Abstract. We derive an upper bound on the action of a direct product of two quantum maps (channels) acting on multi-partite quantum states. We assume that the individual channels $\Lambda_j$ affect single-particle states so, that for an arbitrary input $\rho_j$, the distance $D_j(\Lambda_j[\rho_j], \rho_j)$ between the input $\rho_j$ and the output $\Lambda_j[\rho_j]$ of the channel is less than $\epsilon$. Given this assumption we show that for an arbitrary separable two-partite state $\rho_{12}$ the distance between the input $\rho_{12}$ and the output $\Lambda_1 \otimes \Lambda_2[\rho_{12}]$ fulfills the bound $D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) \leq \sqrt{2 + 2\sqrt{(1 - 1/d_1)(1 - 1/d_2)}} \epsilon$ where $d_1$ and $d_2$ are dimensions of first and second quantum system respectively. On the contrary, entangled states are transformed in such a way, that the bound on the action of the local channels is $D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) \leq 2\sqrt{2 - 1/d} \epsilon$, where $d$ is the dimension of the smaller of the two quantum systems passing through the channels. Our results show that the fundamental distinction between the set of separable and the set of entangled states results into two different bounds which in turn can be exploited for a discrimination between the two sets of states. We generalize our results to multi-partite channels.
1. Introduction

Investigation of properties of communication channels is more than ever today a central issue of information sciences. It is generally accepted that quantum systems have the capacity to carry information efficiently and any transformation of these systems can be considered as an action of a quantum channel (see e.g. Refs. [1, 2, 3, 4, 5]).

Some general questions arising from the transmission of quantum entanglement through quantum channels has been analyzed by Schumacher in Ref. [6]. He has considered a pure entangled state of a pair of two systems $R$ and $Q$ and the system $Q$ has been subjected to a dynamical evolution (quantum channel). Schumacher has shown that the two quantities of interest, the entanglement fidelity $F_e$ and the entropy exchange $S_e$, can be related to various other fidelities and entropies and are connected by an inequality reminiscent of the Fano inequality of classical information theory.

In this paper we address the question how two local channels (each acting independently) do affect a bi-partite quantum state. This scenario is rather general and can be applied to a number of situations, e.g. quantum computation with quantum computer imperfectly isolated from environment or analysis of quantum error correcting codes. In the context of quantum error correction this problem has been addressed by Knill and Laflamme in Ref. [7] for a particular case of two qubits and for a particular choice of a distance (fidelity) characterizing the change of the bi-partite state. In Ref. [8] Aharonov et al. have analyzed errors for a general model of quantum computation with mixed states and non-unitary operations. There however a different measure was introduced. The rationale being that measurable distinguishability of gates (super-operators) should not increase if we consider additional quantum systems which do not evolve. Here on the contrary we are not interested in the distinguishability of superoperators but rather in the actions of the channels on a given state and how to relate these local actions with the change of the global state.

Specifically, consider a pair of quantum channels characterized by maps $\Lambda_1$ and $\Lambda_2$, respectively. It means that after sending a quantum system over, for instance, the first channel the final state of the quantum system (or equivalently the output of the channel) is $\Lambda_1[\rho_1]$ where $\rho_1$ is the corresponding input. Moreover, let the two channels fulfill the following condition

$$D_j(\Lambda_j[\rho_j], \rho_j) \leq \epsilon, \quad \forall \rho_j \in \mathcal{S}(\mathcal{H}_j), \quad j = 1, 2,$$

where $D_j(\cdot, \cdot)$ for $j = 1, 2$ are some distance functions (metric) defined on the set of all density operators $\mathcal{S}(\mathcal{H}_1)$ and $\mathcal{S}(\mathcal{H}_2)$ representing the set of all physically realizable states of quantum systems passing through the channels 1 and 2, respectively. These conditions restrict the action of each of the two channels independently of the action of the other channel. Specifically, the state of a quantum system affected by one of the two channels has to be in a small (epsilon) neighborhood of the state describing the quantum system before the system was sent through the channel.

The parameter $\epsilon$ quantifies the action of the two quantum channels. For $\epsilon = 0$ the two channels are “perfect” (i.e., noiseless, that is, the information transmitted via
channels is not disturbed) as the output equals to the input while for $\epsilon$ large the output can be significantly different from the corresponding input.

The question we would like to address is, how big the change induced by the two local channels is when the inputs are correlated. That is let us prepare an arbitrary initial state $\rho_{12}$ of two quantum systems. The first part of the jointly prepared system is sent over the first channel while the second part is sent over the second channel. Both channels individually fulfill the condition (1), where, e.g. $\rho_1 = \text{Tr}_2 \rho_{12}$. In what follows we will show that the two-partite action of the channel $\Lambda_1 \otimes \Lambda_2$ for all possible physical states $\rho_{12} \in S(H_{12})$ fulfills a bound on its action that is determined by single-partite conditions given by Eq. (1).

Let us note that the problem can be transformed into the estimation of the map $\Omega = \Lambda_1 \otimes \Lambda_2 - \text{Id}_{12}$ where the map $\text{Id}_{12}$ is the identity acting on the joint system. If the distance $D_{12}(\cdot,\cdot)$ as well as distances $D_1(\cdot,\cdot)$ and $D_2(\cdot,\cdot)$ are defined via a norm then our task is to estimate the norm $||\Omega(\rho_{12})||$. Similar expressions for a general class of the so called $p$-norms has been studied extensively for $\Omega$ being a physical map (more specifically the product of two physical maps) in Refs. [9, 10]. However, in our case the map $\Omega$ is neither a positive map nor a direct product of two maps. Due to the fact that the map $\Omega$ is not positive and subsequently not physical our situation is not applicable to Refs. [9, 10] and similar studies.

The paper is organized as follows. In Sec. 2 we introduce necessary definitions and discuss a particular case of separable states, i.e. the initial state of the joint system (the system composed of two quantum systems that are sent over the two quantum channels) is separable. As a next step we drop any assumptions on the initial state and analyze the most general case of an arbitrary initial state in Sec. 3. The results obtained are discussed in Subsection 3.1. In Sec. 4 we extend our analysis to the case of more than two quantum channels and illustrate the nature of changes on a simple example. Finally, in Sec. 5 we summarize our results and outline possible extensions.

2. Separable inputs

In the formulation of the problem we encounter three different metric (distance) functions: $D_1(\cdot,\cdot)$, $D_2(\cdot,\cdot)$ and $D_{12}(\cdot,\cdot)$ acting on different sets and thus measuring distances between different types of objects. In order to make our discussion explicit we will consider a specific choice of the distances offered by the norm of the Hilbert-Schmidt

\[ \|\cdot\|_{HS} \]

Let us note that there is no relation between the parameter $\epsilon$ and the capacity of the channel in general.
spaces corresponding to the systems 1, 2 and the joint system 12, respectively.\footnote{The set of all density operators representing the set of physical states of a quantum system is a subset of a vector space. In such case it is natural to define the metric (distance function) with the help of a norm so that the linear structure of the vector space is respected. There are several ways how to introduce a norm on a vector space. However, the set of all density operators is also a subset of the Hilbert-Schmidt space which is a Hilbert space and we can use the norm induced with the scalar product of the Hilbert space.}

\[
D_a(\rho_a, \sigma_a) \equiv \|\rho_a - \sigma_a\|_a = \sqrt{\text{Tr}_a[(\rho_a - \sigma_a)(\rho_a - \sigma_a)^\dagger]}.
\] (2)

The label $a$ denotes the system 1, 2 or the joint system 12 and $\rho_a, \sigma_a \in \mathcal{S}(\mathcal{H}_a)$ are density operators representing possible physical states of the system labelled $a$. The norms that we have used to define distances $D_1(\ldots)$, $D_2(\ldots)$ and $D_{12}(\ldots)$ are called 2-norms and are only a particular case of the so called $p$-norms. However, due to the fact that we will use only basic properties of the distances $D_1(\ldots)$, $D_2(\ldots)$ and $D_{12}(\ldots)$ we will keep our derivation as general as possible so that it can be repeated with a broad class of different distances. Only in the end we will use the specific choice of distances to derive a tight bound.

Our task is to estimate the distance

\[
D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) ,
\]

for all physically reasonable initial states $\rho_{12} \in \mathcal{S}(\mathcal{H}_{12})$ provided the two maps $\Lambda_1$ and $\Lambda_2$ fulfill the condition \footnote{The set of all density operators representing the set of physical states of a quantum system is a subset of a vector space. In such case it is natural to define the metric (distance function) with the help of a norm so that the linear structure of the vector space is respected. There are several ways how to introduce a norm on a vector space. However, the set of all density operators is also a subset of the Hilbert-Schmidt space which is a Hilbert space and we can use the norm induced with the scalar product of the Hilbert space.} (1). First, note that for any distance inequality (this follows from the triangle property of a distance) holds

\[
D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) \leq D_{12}(\Lambda_1 \otimes \mathbb{1}[\rho_{12}], \rho_{12}) + D_{12}(\mathbb{1} \otimes \Lambda_2[\Lambda_1 \otimes \mathbb{1}[\rho_{12}]].\Lambda_1 \otimes \mathbb{1}[\rho_{12}]).
\]

(4)

It means that instead of considering the case with two local channels it is sufficient to consider only an action of a single local channel acting on one of the two subsystems and estimate the distance $D_{12}(\Lambda_1 \otimes \mathbb{1}[\rho_{12}], \rho_{12})$.

We start with the simplest case - the case of factorizable states of the form $\rho_{12} = \rho_1 \otimes \rho_2$. This corresponds to the situation as if the two channels were considered separately so that the two quantum systems that are sent through the channels are prepared individually. In this case we exploit the following property

\[
D_{12}(\rho_1 \otimes \rho_2, \rho_1 \otimes \rho_2) \leq D_1(\rho_1, \rho_1),
\]

(5)

of the distances $D_1(\ldots)$, $D_2(\ldots)$ and $D_{12}$ where the operators $\rho_1$, $\rho_1'$ and $\rho_2$ are density operators representing states of the first and the second system, respectively. Let us note that this relation holds even if the distances are defined with any $p$-norm or even fidelity. Using Eq. (5) we have that $D_{12}(\Lambda_1 \otimes \mathbb{1}[\rho_1 \otimes \rho_2], \rho_1 \otimes \rho_2) \leq D_1(\Lambda_1[\rho_1], \rho_1)$ and consequently, for the initial state of the form $\rho_1 \otimes \rho_2$, the distance (3) is always less or at most equal to $2\epsilon$

\[
D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_1 \otimes \rho_2], \rho_1 \otimes \rho_2) \leq 2\epsilon ,
\]

(6)
Bounds on action of local quantum channels

due to Eqs. (4) and (11).

The same holds for the initial state $\rho_{12}$ of the form $\rho_{12} = \sum_i \alpha_i \rho_1^i \otimes \rho_2^i$, where $\alpha_i \geq 0$, $\sum_i \alpha_i = 1$ and $\rho_1^i$ and $\rho_2^i$ denote density operators of the system 1 and 2 respectively, that follows from the linearity of the map $\Lambda_1 \otimes \Lambda_2$

$$D_{12}(\Lambda_1 \otimes \Lambda_2 [\sum_i \alpha_i \rho_1^i \otimes \rho_2^i], \sum_i \alpha_i \rho_1^i \otimes \rho_2^i) = D_{12}(\sum_i \alpha_i \Lambda_1 \otimes \Lambda_2 [\rho_1^i \otimes \rho_2^i], \sum_i \alpha_i \rho_1^i \otimes \rho_2^i),$$

and the fact that the distance $D_{12}(.,.)$ is jointly convex, that is

$$D_{12}(\sum_j \alpha_j \Lambda_1 \otimes \Lambda_2 [\rho_1^j \otimes \rho_2^j], \sum_j \alpha_j \rho_1^j \otimes \rho_2^j) \leq \sum_j \alpha_j D_{12}(\Lambda_1 \otimes \Lambda_2 [\rho_1^j \otimes \rho_2^j], \rho_1^j \otimes \rho_2^j).$$

The last expression is a sum of terms where each term is bounded by $2\epsilon$ and the sum of the coefficients $\alpha_i$ is equal to unity. In consequence we obtain the bound

$$D_{12}(\Lambda_1 \otimes \Lambda_2 [\sum_i \alpha_i \rho_1^i \otimes \rho_2^i], \sum_i \alpha_i \rho_1^i \otimes \rho_2^i) \leq 2\epsilon, \quad (7)$$

for an arbitrary separable state.

2.1. Hilbert-Schmidt distance

The bound on the action of a product of two quantum channels on separable states (7) is valid for any triple of distances $D_1(.,.)$, $D_2(.,.)$ and $D_{12}(.,.)$ that satisfy relation (5) (the distance $D_2(.,.)$ has to fulfill the relation (5) with swapped labels 1 and 2) and in addition the distance $D_{12}(.,.)$ has to be jointly convex. That is, the bound is valid if $D_1(.,.)$, $D_2(.,.)$ and $D_{12}(.,.)$ are trace distances or, more generally, the distances defined with $p$-norms or even fidelity. The question is whether it is possible to derive a better (tighter) bound or, in other words, whether the bound is optimal. For the trace distances the bound is optimal indeed and it can be shown that there is a pair of maps such that the bound is saturated. In what follows we will show that for the distances introduced in Eq. (2) the bound can be further optimized.

Let $\rho_1 = 1/d_1 1 + \bar{c}.\bar{\sigma}$ be an input of the channel 1. We have expressed the state of the system labeled as 1 using the identity operator $1$ and $d_1^2 - 1$ generators $\bar{\sigma} = \{\sigma_1, \sigma_2, \ldots\}$ of the group $SU(d_1)$ multiplied with the complex unity where $d_1$ is the dimension of the Hilbert space of the system 1 and the vector $\bar{c} = \{c_1, \ldots\}$ is a real vector with $d_1^2 - 1$ elements. In addition we require that the set of operators $\{\sigma_\alpha\}$ satisfy the ortho-normalization condition $\text{Tr} \sigma_\alpha \sigma_\beta = \delta_{\alpha\beta}$. After the quantum system has been sent through the quantum channel $\Lambda_1$ the state of the system (the output) can be expressed using the same notation $\Lambda_1[\rho_1] = 1/d_1 1 + \bar{c}'.\bar{\sigma}$ with new coefficients $\bar{c'}$ where the prime indicates the fact that the state has been sent through the quantum channel.

The trace distance is defined with the help of the 1-norm and $D(\rho, \sigma)$ is equal to the sum of eigenvalues of the positive operator $|\rho - \sigma|$ where $|\rho - \sigma| = \sqrt{(\rho - \sigma)^\dagger (\rho - \sigma)}$ and $\rho, \sigma \in \mathcal{B}(\mathcal{H})$. ||
Equivalently, $\rho_2 = 1/d_2 \mathbb{1} + \bar{d}.\bar{\tau}$ is the most general state of the system 2 where $\bar{\tau}$ are generators of $SU(d_2)$ multiplied with complex unity, $d_2$ is the dimension of the Hilbert space of the system 2 and the operators $\{\tau_\beta\}$ satisfy relation $\text{Tr} \tau_\beta \tau_\omega = \delta_{\beta\omega}$.

We estimate the distance (3) for an arbitrary separable state and the particular choice of distances (2). Due to the joint convexity of the distance $D_{12}(...)$ and the linearity of the map $\Lambda_1 \otimes \Lambda_2$ it is sufficient to consider the case where the state $\rho_{12}$ is a pure state (for more details see the end of the previous section)

$$\rho_{12} = (1/d_1 \mathbb{1} + \bar{c} \cdot \bar{\sigma}) \otimes (1/d_2 \mathbb{1} + \bar{b} \cdot \bar{\tau})$$

where $\bar{c} \cdot \bar{c} = (1 - 1/d_1)$ and $\bar{b} \cdot \bar{b} = (1 - 1/d_2)$. In this case we do not use the relation Eq. (4) which means that the two channels are not considered separately and the output of the product of the two channels $\Lambda_1$ and $\Lambda_2$ is

$$\Lambda_1 \otimes \Lambda_2[\rho_{12}] = (1/d_1 \mathbb{1} + \bar{c} \cdot \bar{\sigma}) \otimes (1/d_2 \mathbb{1} + \bar{b} \cdot \bar{\tau}) .$$

Inserting the two expressions, input (8) and output (9), into the definition of the distance (2) we obtain that

$$D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) =$$

$$||((\bar{c} \cdot \bar{c}) \cdot \bar{\sigma} \otimes 1/d_2 \mathbb{1} + 1/d_1 \mathbb{1} \otimes (\bar{b} \cdot \bar{b}) \cdot \bar{\tau} + \bar{c} \cdot \bar{\sigma} \otimes \bar{b} \cdot \bar{\tau} - \bar{c} \cdot \bar{\sigma} \otimes \bar{b} \cdot \bar{\tau})||_{12}.$$ (10)

Last expression squared can be bounded from above by a sum of three terms

$$||((\bar{c} \cdot \bar{c}) \cdot \bar{\sigma} \otimes 1/d_2 \mathbb{1})||_{12}^2 + ||1/d_1 \mathbb{1} \otimes (\bar{b} \cdot \bar{b}) \cdot \bar{\tau}||_{12}^2 + [||((\bar{c} \cdot \bar{c}) \cdot \bar{\sigma} \otimes \bar{b} \cdot \bar{\tau})||_{12} + ||\bar{c} \cdot \bar{\sigma} \otimes (\bar{b} \cdot \bar{b}) \cdot \bar{\tau}||_{12}^2].$$

Observing that $||((\bar{c} \cdot \bar{c}) \cdot \bar{\sigma} \otimes 1/d_2 \mathbb{1})||_{12}^2 = 1/d_2 D^2_{2}(|\rho_1|, \rho_1)$, and equivalently $||1/d_1 \mathbb{1} \otimes (\bar{b} \cdot \bar{b}) \cdot \bar{\tau}||_{12} = 1/d_1 D^2_{2}(|\rho_2|, \rho_2)$ and $\bar{b} \cdot \bar{b} \leq (1 - 1/d_2)$ we can bound the distance squared with the expression $1/d_2 \epsilon^2 + 1/d_1 \epsilon^2 + (\sqrt{1 - 1/d_1} + \sqrt{1 - 1/d_2})^2 \epsilon^2$. Finally, the distance between the input and the corresponding output of the product of the two channels fulfills the bound

$$D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) \leq \sqrt{2 + 2\sqrt{(1 - 1/d_1)(1 - 1/d_2)}} \epsilon ,$$ (11)

where $d_1$ and $d_2$ are the dimensions of the Hilbert spaces corresponding to the quantum systems sent through the channels 1 and 2, respectively. Even though we have proved the bound for pure separable states, we note that the result is valid for an arbitrary separable state due to the linearity of the map $\Lambda_1 \otimes \Lambda_2$ and the joint convexity of the distance $D_{12}(...)$. The bound (11) is undoubtedly better than the bound (7) as it has been derived for a specific choice of distances. In addition, it can be shown that the bound is optimal in the sense that there is a pair of maps $\Lambda_1$ and $\Lambda_2$ and a separable state $\rho_{12}$ such that the bound (11) is saturated (optimality is discussed in a more detail in Sec. 5).
3. Entangled states

We have seen that if the initial state of the joint system 12 is factorizable or even separable then the action of the two channels is bounded by the expression $\sqrt{2 + 2\sqrt{(1 - 1/d_1)(1 - 1/d_2)}} \epsilon$ It may be tempting to say that the same holds for an arbitrary state. However, as the next example illustrates, if the joint state of the two systems 1 and 2 is entangled then for certain maps the separable bound can be broken.

Let us consider the Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$ corresponding to the systems 1 and 2 to be two-dimensional spaces. This is the simplest possible case though the physical representations of such systems are numerous. As an example we can mention spin one-half particles, polarized photons or particular internal degrees of freedom of an ion. Let us note that in quantum information theory such systems are denoted as qubits since they represent quantum analogue of a classical bit of information.

Then, any physical state of the system 1 (or equivalently of the system 2) can be written as $\rho_1 = \frac{1}{2}(1 + \vec{\alpha} \cdot \vec{\sigma})$, where $\vec{\alpha} = (\alpha_1, \alpha_2, \alpha_3)$ is a vector in a three dimensional real vector space and the three matrices $\vec{\sigma} = (\sigma_1, \sigma_2, \sigma_3)$ are the well known Pauli operators. For the matrix $\rho_1$ to represent a physical state the norm of the real vector $\vec{\alpha}$ has to be less or equal to 1. It follows that the set of all physically realizable states of the system 1 corresponds to a unit ball (Bloch sphere) in the three dimensional vector space $\mathbb{R}^3$.

The map $\Lambda_1$ we will consider in this particular example is a simple contraction of the ball representing the set of states such that

$$\Lambda_1 : \rho_1 \rightarrow \frac{1}{2}(1 + (1 - k)\vec{\alpha} \cdot \vec{\sigma}), \quad (12)$$

where $(1 - k)$ is a parameter of the contraction. Physically, the map $\Lambda_1$ describes a channel with uncolored (“white”) noise since each input state is mixed with the absolute mixture $1/2 \, 1$ which is the fixed point of the $\Lambda_1$. In order to preserve the condition (1) the parameter $k$ has to fulfill the relation $k \leq \sqrt{2} \epsilon$. In what follows we assume $k = \sqrt{2} \epsilon$.

In the same way the most general state of the system 2 is $\rho_2 = \frac{1}{2}(1 + \vec{\beta} \cdot \vec{\sigma})$, where $\vec{\beta} = (\beta_1, \beta_2, \beta_3)$ is a real vector and $|\beta| \leq 1$. The map $\Lambda_2$ has been chosen to be the same as the map $\Lambda_1$

$$\Lambda_2 : \rho_2 \rightarrow \frac{1}{2}(1 + (1 - k')\vec{\beta} \cdot \vec{\sigma}), \quad (13)$$

with the same contraction parameter $k' = k = \sqrt{2} \epsilon$ so that the condition (11) is fulfilled in this case too.

To show that the separable bound can be broken we have to consider an entangled state. However, we will not consider an arbitrary state but a very specific one - a maximally entangled state known as the Bell state of the form $\rho_{12} = 1/4(|01\rangle - |10\rangle)(|01\rangle - |10\rangle)$, where 0 and 1 denote two basis vectors of $\mathcal{H}_1$ (or $\mathcal{H}_2$). For subsequent calculations it is useful to rewrite the state using the Pauli operators $\rho_{12} = 1/4 (1 - \sigma_1 \otimes \sigma_1 - \sigma_2 \otimes \sigma_2 - \sigma_3 \otimes \sigma_3)$. Inserting $\rho_{12}$ into Eq. (3) and using the linearity of the transformation $\Lambda_1 \otimes \Lambda_2$ as well as Eq. (2) the distance in Eq. (3) reads

$$D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) = \frac{\| -k - k' + kk' \|_{1/2}}{4} \{ \sigma_1 \otimes \sigma_1 + \sigma_2 \otimes \sigma_2 + \sigma_3 \otimes \sigma_3 \}.$$
Both constants, $k$ as well as $k'$ are equal to $\sqrt{2}\epsilon$. Neglecting terms of the order $\epsilon^2$ and evaluating the norm using the scalar product we find

$$D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) \approx \sqrt{6} \epsilon .$$

(14)

This result clearly shows that even though the two maps $\Lambda_1$ and $\Lambda_2$ fulfill the relations (1) the map $\Lambda_1 \otimes \Lambda_2$ constructed as a direct product of the two maps can affect the states it acts on in a much stronger way. How much the joint (and particularly entangled) states can change by two arbitrary maps $\Lambda_1$ and $\Lambda_2$ is addressed in the next paragraph.

Let $\rho_{12}$ be an arbitrary mixed state. The deviation of the output of the channel $\Lambda_1 \otimes \Lambda_2$ from the input $\rho_{12}$ is characterized by the distance Eq. (3). In order to estimate the distance we exploit (as in the case of separable states) the bound given by Eq. (4)

$$D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) \leq D_{12}(\Lambda_1 \otimes 1[\rho_{12}], \rho_{12}) + D_{12}(1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) ,$$

where $\tilde{\rho}_{12} = \Lambda_1 \otimes 1[\rho_{12}]$. As we do not make any assumptions about neither the maps $\Lambda_1$ and $\Lambda_2$ nor the initial state $\rho_{12}$ the two states $\tilde{\rho}_{12}$ and $\rho_{12}$ can be arbitrary physical states of the joint quantum system, i.e. arbitrary density operators. It means that taking, for instance, the first term on the right-hand side of Eq. (15) we need to estimate this term for all possible maps $\Lambda_1$ and all possible states $\rho_{12}$. This fact allows us to rewrite the bound for (3) in a different way

$$D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) \leq 2 \sup_{\{\Lambda_1, \rho_{12}\}} ||\Lambda_1 \otimes 1[\rho_{12}] - \rho_{12}||_{12} ,$$

where the factor 2 appears because we have two terms in Eq. (15) and the supremum runs over all possible maps $\Lambda_1$ and all initial states $\rho_{12}$.

A mixed state $\rho_{12}$ can be decomposed into a mixture of pure states $\rho_{12} = \sum_k \alpha_k |\psi_k\rangle \langle \psi_k|$. Using a basic property of the norm (or joint convexity of the distance) and the normalization condition $\sum_k \alpha_k = 1$ we can simplify the last expression and instead of searching for supremum over all possible states $\rho_{12}$ of the joint system 12 it is sufficient to consider pure states only. It means that

$$D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) \leq 2 \sup_{\{\Lambda_1, |\psi\rangle \langle \psi|\}} ||\Lambda_1 \otimes 1[|\psi\rangle \langle \psi|] - |\psi\rangle \langle \psi||_{12},$$

(16)

where the supremum runs over all possible maps $\Lambda_1$ and all possible pure states $|\psi\rangle \langle \psi| \in \mathcal{S}(\mathcal{H}_{12})$ of the joint system 12. Since we have used only a basic property of the norm the last relation is valid for any distance defined with the help of a norm (or more generally any distance that is jointly convex). However, in what follows we will use specific properties of the Hilbert-Schmidt norm and further results are valid for that particular choice of the norm only.

Any pure state $|\psi\rangle \in \mathcal{H}_{12}$ can be expressed using the Schmidt basis

$$|\psi\rangle = \sum_{k=1}^{n_\psi} \beta_k |k\rangle_1 \otimes |k\rangle_2 ,$$

(17)

Given the fact that we have not specified the dimension of neither the system 1 nor the system 2, the two systems can be different. Therefore we should find supremum over all $\Lambda_1$'s and all $\rho_{12}$ of the first expression in Eq. (15) and all $\Lambda_2$'s and all $\tilde{\rho}_{12}$ of the second expression in Eq. (15). However, the results are the same in both cases.
where \(|k_1\rangle\) and \(|k_2\rangle\) are two sets of orthonormal vectors of \(\mathcal{H}_1\) and \(\mathcal{H}_2\), respectively, and \(\beta_k\) are real positive coefficients. The integer \(n_\psi\) denotes the number of elements in the Schmidt decomposition of the given pure state and is always less or equal to the dimension of the smaller of the two Hilbert spaces \(\mathcal{H}_1\) and \(\mathcal{H}_2\). In this particular basis the state \(\rho_{12} = |\psi\rangle\langle\psi|\) has the form

\[
|\psi\rangle\langle\psi| = \sum_{k,l=1}^{n_\psi} \beta_k \beta_l |k_1\rangle\langle l | \otimes |k_2\rangle\langle l |.
\]

Let us now estimate the expression \(\|\Lambda_1 \otimes 1 [ |\psi\rangle\langle\psi|] - |\psi\rangle\langle\psi| \|_{12}^2\) from Eq. (16). Using Eq. (18) for the density operator \(|\psi\rangle\langle\psi|\) and tracing over the degrees of freedom belonging to the second system we have that

\[
\|\Lambda_1 \otimes 1 [ |\psi\rangle\langle\psi|] - |\psi\rangle\langle\psi| \|_{12}^2 = \sum_{k,l=1}^{n_\psi} \beta_k^2 \beta_l^2 Tr_1 V_{kl}(V_{kl})^\dagger,
\]

where \(V_{kl} = \Lambda_1 |k_1\rangle\langle l | - |k_1\rangle\langle l |\). At this point we apply the relations Eqs. (A.1), (B.1) and (B.2) (proved in Appendix A and Appendix B) and Eq. (1) that establish the following inequalities

\[
Tr_1 V_{kl}(V_{kl})^\dagger \leq 2\epsilon^2 ; \quad \forall k \neq l ;
\]

\[
Tr_1 V_{kk}(V_{kk})^\dagger \leq \epsilon^2 ; \quad \forall k .
\]

These inequalities bound each contribution (trace term) in the sum on the right of Eq. (19). If we replace each term with the corresponding bound and maximize over all possible \(\beta_j\) then we do estimate the expression on the left-hand side of the last equality as

\[
\|\Lambda_1 \otimes 1 [ |\psi\rangle\langle\psi|] - |\psi\rangle\langle\psi| \|_{12}^2 \leq (2 - 1/d) \epsilon^2,
\]

where \(d\) is the dimension of the smaller of the two Hilbert spaces \(\mathcal{H}_1\) and \(\mathcal{H}_2\) in case the two subsystems 1 and 2 are different. Since the result is independent of both the map \(\Lambda_1\) and the state \(|\psi\rangle\langle\psi|\) it holds for all maps \(\Lambda_1\) and all density operators \(|\psi\rangle\langle\psi|\) (representing pure states). Consequently, the supremum over all maps \(\Lambda_1\) and all pure states \(\rho_{12}\) is less or equal to this value and so is the distance (3)

\[
D_{12}(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) \leq 2\sqrt{2 - 1/d} \epsilon.
\]

The bound (20) is valid for entangled as well as separable states. However, for separable states we have already found a tighter bound \(\sqrt{2 + 2\sqrt{(1 - 1/d_1)(1 - 1/d_2)}}\epsilon\) [see Eq. (11)] which means that the entangled states can be affected by independent channels more strongly than separable states.

\[\text{+ If the two subsystems 1 and 2 are different then the number of elements in the Schmidt decomposition Eq. (17) \(n_\psi\) is always less or equal to \(d\) - the dimension of the smaller of the two Hilbert spaces \(\mathcal{H}_1\) and \(\mathcal{H}_2\). Consequently, the number of coefficients \(\beta_j\) we maximize over is always bounded by this number, which in turn bounds the maximum.}\]
3.1. Detection of entanglement

The difference in the behavior of separable and entangled states resulted into two different bounds. The bound for entangled states is weaker and this bound is obeyed by entangled as well as separable states. On the other hand the bound for separable states Eq. (11) is tighter and need not be fulfilled by entangled states. Subsequently, any state that violates the bound (11) is necessarily entangled and a direct product of physical channels can be exploited as a kind of “entanglement witness”. Let us point out that the entanglement witnesses known in the literature, Refs. [11, 12], are based on a different approach. They are constructed using positive but not completely positive maps (that is non-physical maps) acting on one of the two subsystems and the non-positivity of the final operator (output) is the indication of entanglement. On the contrary, in our case, we have a product of two physical maps so that a physical (completely positive) map is acting on each of the two subsystems and the difference between an input and the corresponding output is measured. In addition there is a potential advantage in this approach. Not only the question whether a state is entangled or separable can be answered. If we relate the distance to entanglement then we could answer the question how much entanglement is shared by two quantum systems.

Similarly as in the case of entanglement witnesses, given a pair of maps, the detection need not be (and in general is not) perfect. In other words given a pair of channels only a subset of the set of all entangled states violates the bound Eq. (11) and those are the only states that are detected as entangled. Naturally, it is desirable to optimize the detection so that the whole set of entangled states is detected. There are several things we can do to optimize the detection of entangled states using quantum channels:

(i) Optimal choice of the distances $D_1(.,.), D_2(.,.)$ and $D_{12}(.,.)$
(ii) Optimal choice of the pair of channels (maps $\Lambda_1$ and $\Lambda_2$) and subsequent derivation of the bound for separable states for that particular choice.

It is obvious that both elements influence detection of entanglement. Let us point out that the choice of maps is not limited to physical channels. The problem is usually formulated as follows: Given a density matrix of a bipartite system how strongly the two subsystems are entangled. That is we have a complete knowledge of the elements of the density matrix and we are allowed to execute arbitrary operation (function) on the matrix to calculate the entanglement. Such operation can be non-physical and even non-linear. Construction of entanglement witnesses using a general class of non-physical but linear maps has been investigated in Ref. [13]. The authors have showed that with the help of linear maps it is possible to distinguish perfectly the set of entangled states from the set of separable states. Here we show that this approach could be useful not only for the problem of detection but also for the problem of quantifying entanglement.

Let us express the most general bipartite two-qubit state $\rho_{12}$ using the Pauli
operators $\sigma_j$, $j = 1, 2, 3$

$$\rho_{12} = \frac{1}{4} \left[ 1 + \sum_{j=1}^{3} \alpha_j \sigma_j \otimes 1 + \sum_{k=1}^{3} 1 \otimes \sigma_k + \sum_{j,k=1}^{3} \gamma_{jk} \sigma_j \otimes \sigma_k \right],$$

where $\alpha_j$, $\beta_k$ and $\gamma_{jk}$ for $j,k = 1, 2, 3$ are real parameters. Further, consider a linear map $\Lambda_{12}$

$$\Lambda_{12} : \rho_{12} \rightarrow \rho_{12} + \frac{\epsilon}{4} \left( -1 + \sum_{j,k=1}^{3} \gamma_{jk} \sigma_j \otimes \sigma_k \right). \quad (21)$$

With the help of the map (21) and the trace distance we define the following function

$$F(\rho_{12}) \equiv \frac{1}{\epsilon} \text{Tr}_{12} |\Lambda_{12}[\rho_{12}] - \rho_{12}| - 1. \quad (22)$$

The factor $1/\epsilon$ is there to eliminate the dependence on the epsilon while the $-1$ has been added for a convenience only. The function $F$ has the following properties:

(i) $F(\sum_j \lambda_j \rho_{12}^j) \leq \sum_j \lambda_j F(\rho_{12}^j)$, convexity.

(ii) $F(U_1 \otimes U_2 \rho_{12} U_1^\dagger \otimes U_2^\dagger) = F(\rho_{12})$, local unitary equivalence $\forall U_1$ and $\forall U_2$.

(iii) $F(\rho_{12}) \geq 0$, $\forall \rho_{12}$, non-negativity.

(iv) $F(\rho_{12}) = 0$, for all separable states.

(v) $F(\rho_{12}) = C(\rho_{12})$, where $\rho_{12}$ is pure or Werner state (for definition of the Werner state see Ref. [14]) and $C(\rho_{12})$ is the concurrence (see Ref. [15]).

Through the extension of the proposed method to non-physical maps and a suitable choice of the map acting on the joint state $\rho_{12}$ we have managed to construct a function that detects entanglement on all Werner states. Moreover, some of the listed properties of the function $F$ are supposed to be fulfilled by a function that not only distinguishes separable and entangled states but performs a harder task - measures entanglement between two quantum systems. Though, the constructed function is not a proper measure of entanglement (there are entangled states for which $F$ is zero) a suitable extension might “correct” the function so that all entangled states are detected.

4. $N$ channels

In many physical situations it is less convenient to divide the system under consideration into two large subsystems than into a large number (say $N$) of smaller (but equal systems). Typical example is the envisaged quantum computer composed of small micro-traps each holding a single qubit. In such case individual qubits are spatially separated so that the interaction with environment can be described by local maps $\Lambda_i$ where the index $i$ labels the qubits (or micro-traps). These maps can be derived phenomenologically or determined experimentally so their knowledge can be assumed. Obviously, we want to keep the influence of the environment as small as possible so each of the maps would satisfy a condition similar to Eq. (11)

$$D_i(\Lambda_i[\rho_i], \rho_i) \leq \epsilon; \quad \forall i = 1,..N, \forall \rho_i \in \mathcal{S}(\mathcal{H}_i), \quad (23)$$
where $D_i(.,.)$’s are again metrics (distance functions) and $S(\mathcal{H}_i)$ is the set of all density operators for each $i = 1, \ldots N$. Using these maps we can find out the state of a particular qubit after interaction with the environment. However, what is more important is the final state of the whole system

$$\Lambda_1 \otimes \ldots \otimes \Lambda_N[\rho_{1..N}] ,$$

and, in particular, how much the joint state $\rho_{1..N}$ has changed due to the interaction with the environment. This change can be characterized by a distance between the original state $\rho_{1..N}$ and the output of the product of the individual maps given by Eq. (24)

$$D_{1..N}(\Lambda_1 \otimes \ldots \otimes \Lambda_N[\rho_{1..N}],\rho_{1..N}) ,$$

where the $D_{1..N}$ is a metric (distance function) defined on the set of all density operators $S(\mathcal{H}_{1..N})$ of the joint system $1..N$. Here we use the same definition of the metric (distance) as before and define the functions $D_i(.,.)$ for $j = 1, \ldots N$ and $D_{1..N}(.,.)$ with the help of the norm of the corresponding Hilbert-Schmidt space (for more details see Sec. [2])

$$D_i(\rho,\sigma) \equiv ||\rho - \sigma||_i ,$$

$$D_{1..N}(\rho,\sigma) \equiv ||\rho - \sigma||_{1..N} .$$

Using these definitions it can be shown that the distance in Eq. (25) is always less or equal to $N \sqrt{2 - 1/d \epsilon}$ where $d$ is the dimension of the Hilbert space $\mathcal{H}_i$.

We note that the action of the product of local channels $\Lambda_1 \otimes \ldots \otimes \Lambda_N$ on separable states is such that $D_{1..N}(\Lambda_1 \otimes \ldots \otimes \Lambda_N[\rho_{1..N}],\rho_{1..N}) \leq N \epsilon$. This means, that the restriction to the set of separable states leads to the decrease of the bound on $D_{1..N}$ by the factor $\sqrt{2 - 1/d \epsilon}$.

To prove the statement we will use a very similar line of reasoning as in the case of two subsystems. First, taking advantage of the triangle inequality we bound the distance in Eq. (25) as follows:

$$D_{1..N}(\Lambda_1 \otimes \ldots \otimes \Lambda_N[\rho_{1..N}],\rho_{1..N}) \leq \sum_{i=1}^{N} D_{1..N}(\rho_{1..N},\rho_{1..N}) .$$

Each of the $N$ terms on the right side of the last equation can be rewritten as

$$D_{1..N}(1 \otimes \ldots \otimes 1 \otimes \Lambda_i \otimes 1 \otimes \ldots \otimes 1[\rho_{1..N}^{(i)}],\tilde{\rho}_{1..N}^{(i)}) ,$$

where

$$\tilde{\rho}_{1..N}^{(i)} = 1 \otimes \ldots \otimes 1 \otimes \Lambda_{i+1} \otimes \Lambda_{i+2} \otimes \ldots \Lambda_N[\rho_{1..N}] ,$$

* Here we have used the bound (7) for separable states that can be easily extended to a multi-partite case.
so it is sufficient to bound the expression (29). Next, we divide the whole system into two parts, an elementary system $i$ and the rest. From this point the proof takes the same lines as in the case of two subsystems discussed in the Sec. 3. Therefore we recall the result Eq. (20) obtained there and refer the reader to the Sec. 3 for more details. The Eq. (20) states that

$$D_{1\ldots N}(\mathbb{1} \otimes \ldots \otimes \Lambda_i \otimes \mathbb{1} \otimes \ldots \otimes \tilde{\rho}_{1\ldots N}^{(i)}, \tilde{\rho}_{1\ldots N}^{(i)}) \leq \sqrt{2 - 1/d},$$

where $d$ is the dimension of the $i$-th elementary subsystem. Since we have $N$ terms in the expression on the right in Eq. (28) the distance (25) is bounded by

$$D_{1\ldots N}(\Lambda_1 \otimes \ldots \otimes \Lambda_N[\rho_{1\ldots N}], \rho_{1\ldots N}) \leq N \sqrt{2 - 1/d} \epsilon,$$  

where $N$ is the number of elementary subsystems each satisfying the condition (26) and $d$ is the dimension of the Hilbert spaces $\mathcal{H}_i$ corresponding to the elementary subsystems.

4.1. Example

To illustrate the character of changes induced by the local maps on the global state of the whole system let us consider a simple model of $N$ qubits undergoing a process of decoherence. That is the Hilbert spaces $\mathcal{H}_i$ are two-dimensional and the maps $\Lambda_i$ are chosen to be

$$\Lambda_i : \frac{1}{2}(\mathbb{1} + \tilde{\alpha} \cdot \tilde{\sigma}) \rightarrow \frac{1}{2} \left\{ \mathbb{1} + \alpha_3 \sigma_3 + (1 - k)[\alpha_1 \sigma_1 + \alpha_2 \sigma_2] \right\},$$

where $k$ is equal to $k = \sqrt{2} \epsilon$ in order to fulfill the conditions Eq. (23). The action of the map $\Lambda_i$ is such that it preserves the diagonal elements in basis formed by the eigenvectors of $\sigma_3$ while the non-diagonal elements are suppressed. Such maps describe the process of dephasing, a particular case of decoherence, since the vanishing of off-diagonal elements results into states that describe statistical mixtures.

Consider the initial state of the joint system to be the Greenberger-Horn-Zeiliner (GHZ) state

$$\rho_{1\ldots N} = \frac{1}{2} \left\{ |0\ldots 0\rangle \langle 0\ldots 0| + |0\ldots 0\rangle \langle 1\ldots 1| + |1\ldots 1\rangle \langle 0\ldots 0| + |1\ldots 1\rangle \langle 1\ldots 1| \right\}.$$  

The action of the map $\Lambda_1 \otimes \ldots \otimes \Lambda_N$ on the state $\rho_{1\ldots N}$ described above can be evaluated straightforwardly and we obtain

$$\Lambda_1 \otimes \ldots \otimes \Lambda_N[\rho_{1\ldots N}] = \frac{1}{2} \left\{ |0\ldots 0\rangle \langle 0\ldots 0| + |1\ldots 1\rangle \langle 1\ldots 1| + (1 - k)^N( |0\ldots 0\rangle \langle 1\ldots 1| + h.c.) \right\}.$$  

Despite the fact that the state of each individual qubit remains unchanged (a consequence of this is that the conditions (23) are trivially fulfilled) the state of the whole system changes because the off-diagonal elements are strongly suppressed. The distance (25) between the input $\rho_{1\ldots N}$ and the corresponding output $\Lambda_1 \otimes \ldots \Lambda_N[\rho_{1\ldots N}]$
Bounds on action of local quantum channels

14

gives

\[ D(\Lambda_1 \otimes \cdots \otimes \Lambda_N[\rho_{1\ldots N}], \rho_{1\ldots N}) = \sqrt{\frac{1}{2} [1 + (1 - k)^{2N} - 2(1 - k)^N]} , \]

which for \( \epsilon \) being very small can be estimated as

\[ D(\Lambda_1 \otimes \cdots \otimes \Lambda_N[\rho_{1\ldots N}], \rho_{1\ldots N}) \approx N \epsilon . \]

The deviation of the GHZ state under the action of the direct product of local maps \( \Lambda_i \) for sufficiently small \( \epsilon \) scales as \( N \epsilon \) which confirms our more general result Eq. (30).

Though the result may seem to be optimistic (one might expect worse scaling with \( N \)) the effect of the action of local maps is to disentangle the qubits (destroy quantum correlations between the qubits). In addition, the disentanglement itself is strong since the off-diagonal elements are suppressed exponentially with the increase of the number of systems involved in the dynamics. This example nicely illustrates that though the deviation expressed with the help of the distance (25) scales as \( N \epsilon \) the entanglement may be destroyed much more dramatically.

Finally note that in this example the bound for separable states \( N \epsilon \), derived with the help of Eq. (17), is not violated in spite of the fact that we have used an entangled state. We have already pointed out that it is not necessary for any entangled state to violate the separable bound. To show that the bound can be violated indeed one can choose the map \( \Lambda_1 \) defined in Sec. 3 for maps \( \Lambda_i \) and the initial state of the form \(|\text{bell}\rangle \otimes N/2 \) where \(|\text{bell}\rangle \) denotes one of the Bell states (see, for instance, Sec. 3).

5. Conclusion

We have analyzed the direct product of linear maps that describe local actions of a set of quantum channels. We have found a bound on the action of such product of maps (expressed as a distance between an input and output of the product) provided the linear maps composing the product are bounded as well. We have addressed two typical scenarios. In the first, a quantum system is divided into two subsystems and the product is composed of two maps acting on the two subsystems, respectively. In the second scenario a joint system is composed of \( N \) equal subsystems and we have \( N \) linear maps acting on \( N \) subsystems of a given quantum system.

Our analysis has shown that the fundamental difference between the set of separable and entangled states yields two different bounds. For separable states the distance Eq. (3) is bounded by \( \sqrt{2 + 2 \sqrt{(1 - 1/d_1)(1 - 1/d_2)} \epsilon} \) while in the case of entangled states the distance can be larger and is bounded from above by \( 2 \sqrt{2 - 1/d} \epsilon \).

Let us note that the bound for separable states (11) is optimal. That is there exists a pair of channels \( \Lambda_1 \) and \( \Lambda_2 \) such that the bound is saturated (examples are presented in Appendix C). It is interesting to note that the channels that saturate the bound are the same channels that saturate the separable bound (17) for the case of the trace distance (see Appendix C) or the bound (20) for entangled states in case of
two-dimensional systems. Clearly, to establish the upper bound on the action of a pair of local quantum channels it is sufficient to find a pair of channels for which the action is maximal and set the bound to this maximum. The form of the channels may depend on the dimensions $d_1$ and $d_2$. However, our results suggest that the channels for which the bounds are maximal are of the same form for arbitrary $d_1$ and $d_2$ and are the channels that we have used in our examples.

In the end let us point out that our analysis is not restricted to the case of physical maps only and can be extended to the case of linear and hermicity preserving maps that are not physical.

**Appendix A.**

We prove the relation

$$
|| \Lambda[ |k\rangle\langle l|] - |k\rangle\langle l| ||^2 = || \Lambda[ |l\rangle\langle k|] - |l\rangle\langle k| ||^2 = \\
\frac{1}{4} \left\{ || \Lambda[ (|k\rangle\langle l| + |l\rangle\langle k|)] - (|k\rangle\langle l| + |l\rangle\langle k|) ||^2 \\
+ || \Lambda[ (|k\rangle\langle l| - |l\rangle\langle k|)] - (|k\rangle\langle l| - |l\rangle\langle k|) ||^2 \right\} .
$$

(A.1)

for all physical (linear, hermicity preserving and completely positive) maps $\Lambda$ with the norm defined in Eq.(2) and $k \neq l$.

Let us denote by $V_{kl}$ the expression $\Lambda[ |k\rangle\langle l|] - |k\rangle\langle l|$. Using the definition of the norm in Eq. (2) we have that for any physical map $\Lambda$

$$
|| \Lambda[ |k\rangle\langle l|] - |k\rangle\langle l| ||^2 = \text{Tr} V_{kl} V_{kl}^\dagger , \\
|| \Lambda[ |l\rangle\langle k|] - |l\rangle\langle k| ||^2 = \text{Tr} V_{kl}^\dagger V_{kl} , \\
|| \Lambda[ (|k\rangle\langle l| + |l\rangle\langle k|)] - (|k\rangle\langle l| + |l\rangle\langle k|) ||^2 = \text{Tr} (V_{kl} + V_{kl}^\dagger)(V_{kl}^\dagger + V_{kl}) , \\
|| \Lambda[ (|k\rangle\langle l| - |l\rangle\langle k|)] - (|k\rangle\langle l| - |l\rangle\langle k|) ||^2 = \text{Tr} (V_{kl} - V_{kl}^\dagger)(V_{kl}^\dagger - V_{kl}) .
$$

Eq. (A.1) is a direct consequence of the last result.

**Appendix B.**

In this appendix we prove two relations

$$
|| \Lambda[ (|k\rangle\langle l| + |l\rangle\langle k|)] - (|k\rangle\langle l| + |l\rangle\langle k|) || \leq 2\epsilon , \quad \text{(B.1)} \\
|| \Lambda[ (|k\rangle\langle l| - |l\rangle\langle k|)] - (|k\rangle\langle l| - |l\rangle\langle k|) || \leq 2\epsilon . \quad \text{(B.2)}
$$
for all physical (linear, completely positive and hermicity preserving) maps \( \Lambda \) satisfying
the condition given by Eq. (1) and \( k \neq l \). The two expressions

\[
\| \Lambda [ (|k\rangle \langle l| + |l\rangle \langle k|)] - (|k\rangle \langle l| + |l\rangle \langle k|)] \|
\]

\[
\| \Lambda [ (|k\rangle \langle l| - |l\rangle \langle k|)] - (|k\rangle \langle l| - |l\rangle \langle k|)] \|
\]

can be rewritten as

\[
\| \Lambda [ (\rho_1 - \rho_2)] - (\rho_1 - \rho_2) \|
\]

\[
\| \Lambda [ i(\rho_3 - \rho_4)] - i(\rho_3 - \rho_4) \|
\]

where

\[
\rho_1 = \frac{1}{2} (|k\rangle + |l\rangle)( h.c. )
\]

\[
\rho_2 = \frac{1}{2} (|k\rangle - |l\rangle)( h.c. )
\]

\[
\rho_3 = \frac{1}{2} (|k\rangle + i|l\rangle)( h.c. )
\]

\[
\rho_4 = \frac{1}{2} (|k\rangle - i|l\rangle)( h.c. ).
\]

By using the triangle inequality

\[
\| \Lambda [ (\rho_1 - \rho_2)] - (\rho_1 - \rho_2) \| \leq \| \Lambda [ \rho_1] - \rho_1 \| + \| \Lambda [ \rho_2] - \rho_2 \|
\]

\[
\| \Lambda [ i(\rho_3 - \rho_4)] - i(\rho_3 - \rho_4) \| \leq \| \Lambda [ \rho_3] - \rho_3 \| + \| \Lambda [ \rho_4] - \rho_4 \|
\]

we obtain the relations Eq. (B.1) and Eq. (B.2) owing to the conditions Eq. (1).

Appendix C.

Here we present an example showing that the bounds (7) and (11) are optimal. In this example we will consider a more general case of distances \( D_{1}(...) \), \( D_{2}(...) \) and \( D_{12}(...) \) and define the distances with \( p \)-norms

\[
D_{a}^{p}(\rho_a, \sigma_a) = \langle \text{Tr}[\rho_a - \sigma_a]^{p}\rangle^{1/p},
\]

where \( a \) labels the system 1, 2 or 12, \( \rho_a \) and \( \sigma_a \) are density operators and \( p \) is a positive integer. The map \( \Lambda_1 \) is chosen to be a contraction of the form

\[
\Lambda_1[\rho_1] = (1 - k_1) \rho_1 + k_1 \frac{1}{d_1} \mathbb{1},
\]

where \( d_1 \) is the dimension of the Hilbert space \( \mathcal{H}_1 \) and \( k_1 \) is the contraction parameter. In what follows we assume \( k_1 = \epsilon /[(1 - 1/d_1)^{p} + (d_1 - 1)/d_1]^{1/p} \) so that the condition (11) is fulfilled. Similarly, the map \( \Lambda_2 \) is a contraction

\[
\Lambda_2[\rho_2] = (1 - k_2) \rho_2 + k_2 \frac{1}{d_2} \mathbb{1},
\]

where \( d_2 \) is the dimension of the Hilbert space \( \mathcal{H}_2 \) and \( k_1 = \epsilon /[(1 - 1/d_2)^{p} + (d_2 - 1)/d_2]^{1/p} \). For the initial state we choose a pure state of the form \( \rho_{12} = |00\rangle \langle 00| \). Keeping only
terms of the order of $\epsilon$ the distance between the input $\rho_{12}$ and the output $\Lambda_1 \otimes \Lambda_2[\rho_{12}]$ gives

$$D_{12}^p(\Lambda_1 \otimes \Lambda_2[\rho_{12}], \rho_{12}) = \left(\frac{k_1}{d_1} \left(1 - \frac{1}{d_1}\right) + \frac{k_2}{d_2} \left(1 - \frac{1}{d_2}\right)\right)^p + \left[\frac{k_1}{d_1} \left(1 - 1/d_1\right)\right]^p + \left[\frac{k_2}{d_2} \left(1 - 1/d_2\right)\right]^p \right)^{1/p}. \quad (C.1)$$

**Case study: Trace distance**

The trace distance is defined with the help of the 1-norm so that $p = 1$. The two contraction parameters $k_1$ and $k_2$ read $k_1 = \epsilon/[2(1 - 1/d_1)]$ and $k_2 = \epsilon/[2(1 - 1/d_2)]$. Using these relation in Eq. (C.1) the distance between the input and the output reads

$$D_{12}(\Lambda_1 \otimes \Lambda_1[\rho_{12}], \rho_{12}) = 2\epsilon. \quad (C.2)$$

**Case study: Hilbert-Schmidt distance**

The Hilbert-Schmidt distance is defined with the help of the 2-norm so that $p = 2$. The two contraction parameters $k_1$ and $k_2$ read $k_1 = \epsilon/\sqrt{1 - 1/d_1}$ and $k_2 = \epsilon/\sqrt{1 - 1/d_2}$. Using these relations in Eq. (C.1) the distance between the input and the corresponding output reads

$$D_{12}(\Lambda_1 \otimes \Lambda_1[\rho_{12}], \rho_{12}) = \sqrt{2 + 2\sqrt{(1 - 1/d_1)(1 - 1/d_2)} \epsilon}. \quad (C.3)$$
