We give a complete classification of mass dimension five Lorentz-non-invariant interactions composed from the Standard Model fields, using the effective field theory approach. We identify different classes of Lorentz violating operators, some of which are protected against transmutation to lower dimensions even at the loop level. Within each class of operators we determine a typical experimental sensitivity to the size of Lorentz violation.
I. INTRODUCTION

Lorentz symmetry is one of the most important ingredients of the Standard Model (SM) of particles and fields, as well as its extensions at the electroweak scale. Even though there is a robust evidence that Lorentz symmetry is maintained to a high degree of accuracy, the searches of the so-called ”Lorentz Violation” (LV) are still reasonably well-motivated. The intriguing possibility is that an a priori unknown physics at high energy scales could lead to a spontaneous breaking of Lorentz invariance by giving an expectation value to certain non-SM fields that carry Lorentz indices, such as vectors, tensors, and gradients of scalar fields. The interaction of these fields with operators composed from the SM fields, fully Lorentz-symmetric before the spontaneous breaking, below the scale of the condensation will manifest itself as effective LV terms. Schematically, one has

\[ O_{\mu\nu...}^{SM} C_{\mu\nu...} \rightarrow O_{\mu\nu...}^{SM} \langle C_{\mu\nu...} \rangle, \]  

where \( C_{\mu\nu...} \) is an external field that undergoes condensation, and \( O_{\mu\nu...}^{SM} \) is the SM operator that transforms under the Lorentz group. It would be fair to say that the dynamical breaking of Lorentz invariance is difficult to achieve in a consistent UV-complete theory, and most of the papers studying LV shy away from this issue. Nevertheless, leaving aside the question of the dynamical LV, the spurion or the effective field theory approach to the problem \[1, 2\] has been instrumental in comparing the sensitivity of various LV tests.

If the generation of interaction (1) is a true UV phenomenon, it proves extremely useful to classify all operators of lowest dimensions coupled to a given spurion field \( C_{\mu\nu...} \). At dimension three and four levels, this was done nearly a decade ago by Colladay and Kostelecky [1, 2, 3]. Dimension three Lorentz violating interactions, e.g. \( b^\mu \psi \bar{\gamma}_\mu \gamma_5 \psi \) and \( a^\mu \psi \bar{\gamma}_\mu \psi \), must defy the naive dimensional counting, according to which \( a^\mu \) and \( b^\mu \) scale linearly with the UV energy scale responsible for LV, \( a^\mu, b^\mu \sim \Lambda_{UV} \). This is, of course, in a stark contradiction with reality, where typical values for e.g. \( b_\mu \) of light quarks are known to be smaller than \( 10^{-31} \) GeV. It can be hypothesized that spurions at dimension three and four levels are in fact not fundamental, but indeed effective, implying a different type of scaling, e.g. \( a^\mu, b^\mu \sim \Lambda_{IR}^2/\Lambda_{UV} \), where \( \Lambda_{IR} \) is the energy scale associated with the SM. The appearance of \( \Lambda_{UV} \) in the denominator implies that above the scale \( \Lambda_{IR} \) one should be able to formulate all LV interactions in terms of the higher-dimensional LV operators.
The purpose of this paper is to give a complete account of LV operators of dimension five in QED and in the SM. Previously, only certain subclasses of higher-dimensional operators have been considered. Notably, dimension six LV operators and their phenomenological consequences have been studied at length in the context of the canonical non-commutative field theories [4, 5, 6, 7]. The operators that introduce the UV modifications of the dispersion relations for particles have been a subject of intense investigations over a number of years [3, 8, 9, 10, 11, 12, 13, 14]. Finally, the supersymmetrized versions of the dimension five LV operators have been studied in detail in [15, 16]. Our paper includes all previously known cases of LV dimension five interactions, but also extends LV to operators that have never been discussed in the literature.

Our intention is to write down a generic LV theory with mass dimension five interactions, compatible with the Standard Model and to classify the inherent LV operators. We count the dimension of the SM operators $O_{\mu\nu...}^{\text{SM}}$, and thus dimension five corresponds to all background LV spurions to be of the inverse energy scale. It is easy to see that a theory with LV interactions of mass dimension five admits a more diverse set of operators and as a consequence more LV backgrounds $C_{\mu\nu...}^{\text{LV}}$ than one has at dimension three and four levels. Since there is a significant freedom in the choice of LV spurions, we take an approach that each of them represents an irreducible Lorentz tensor structure, which leads to a significant facilitation of the analysis of loop effects, and often protects dimension five operators from transmuting into lower dimensions when the quantum effects are taken into account. Thus, we augment the requirements specified in [11] by demanding that LV spurions be irreducible tensors under the Lorentz group transformations. In total, these conditions look as follows: an LV operator of specific dimension must be

- gauge invariant
- Lorentz invariant, after contraction with a background tensor
- not reducible to lower dimension operators by the equations of motion
- not reducible to a total derivative
- coupled to an irreducible background tensor.

We find that operators built in this manner can be subdivided into three main groups. The first group includes the “unprotected operators”, \( i.e. \) those which can generate lower-
dimensional interactions by developing quadratic divergencies. Such operators are therefore
dangerous, and as a rule, severely constrained by strong limits on lower dimensional operators
multiplied by the square of the UV scale. The second group is the UV-enhanced operators,
which induce modifications of the dispersion relations that grow with particle’s energy.
These operators induce new testable LV signatures in the laboratory experiments and in
astrophysics, and are severely constrained by both. The last group is formed by “soft LV
interactions” which are protected from developing quadratic divergencies at loop level and
do not significantly modify the propagation of energetic particles in the UV. Typically, such
operators are constrained by the laboratory searches of spatial anisotropy.

The structure of this paper is as follows. In Section II we analyze the case of Quantum
Electrodynamics (QED), extended by all possible LV interactions of dimension five. QED is
one of the most popular testing grounds for LV \cite{3, 8, 11, 16, 17}, and the detailed study of LV
QED facilitates a smooth transition to the Standard Model. Within QED, we develop one-
loop renormalization group equations for the LV interactions. Going over to the Standard
Model in Section III, we observe that the chirality of matter fields imposes further restrictions
on the type of admissible LV interactions. However, the abundance of field content makes
possible for more diverse structures and links between them. A complete RG analysis in
the Standard Model may be highly desirable for refining the phenomenological constraints
on LV operators. However, due to the excessively complicated structure of interactions, we
only elaborate on the example of operators which modify dispersion relations, which are of
the most phenomenological interest. In Section IV, we subdivide operators into the major
groups according to their phenomenological consequences and give a brief account of typical
limits one can expect from the currently available tests of Lorentz violation.

II. DIMENSION 5 OPERATORS IN QED

In order to build a Lorentz-violating extension of QED, we take an approach similar to
Myers-Pospelov electrodynamics \cite{11}. The Lagrangian of QED was modified by adding a
number of LV operators which were generated by an absolutely symmetric 3-rank irreducible
tensor background. Originally, the choice of symmetric tensors was motivated by the fact
that LV operators can modify the dispersion relations, and also that they do not induce
dangerous quadratic divergencies. Our intention is to classify all dimension five operators
in Quantum Electrodynamics, and thus the list of the external LV tensors will necessarily be expanded. Generic operators will produce new non-minimal interactions between the electron and the photon. The LV extension of the photon sector of QED appears to be the most simple, whereas the matter sector shows a rich structure of LV terms.

A. Purely Gauge Operators in QED

Dimension five LV interactions can admit LV backgrounds up to rank five. Higher ranks can appear only in combination with operators of dimension six or higher. There are 26 numbered Young tableaux to consider, which in fact lead to only one LV operator.

It can be shown that a generic content of a gauge invariant tensor has to be bilinear in the field strength $F_{\mu\nu}$ and contain one extra derivative, which must be a covariant derivative in the case of a non-abelian field.

The only non-vanishing terms that satisfy these properties are

$$F_{\mu\nu} \partial^\nu F^{\mu\rho}, \quad F_{\mu\nu} \partial^\nu F^{\rho\sigma}, \quad F_{\mu\lambda} \partial_{\nu} F^{\rho\lambda} \quad \text{and} \quad F^{\mu\nu} \partial^{\lambda} F^{\rho\sigma}. \quad (2)$$

It can be easily seen that the first two terms are reducible on the equations of motion, and, in accord with our requirements should be ignored. Amongst the two structures left, $F_{\mu\lambda} \partial_{\nu} F^{\rho\lambda}$ and $F^{\mu\nu} \partial^{\lambda} F^{\rho\sigma}$, the first has been studied in [11] and shown to modify the dispersion relations of the photon. It was shown in particular that this operator has to be contracted with an irreducible absolutely symmetric tensor,

$$C^{\mu\nu\rho} F_{\mu\lambda} \partial_{\nu} F^{\rho\lambda}, \quad C^{\mu\rho} = 0. \quad (3)$$

Conditions of absolute symmetry and irreducibility of the tensor $C^{\mu\nu\rho}$ follow from the requirement of independence of this operator of the lower-rank operators of (2), which is also a way of protection against the mixing with such operators at the loop level.

The last structure in (2), the five-index object $F^{\mu\nu} \partial^{\lambda} F^{\rho\sigma}$, upon a naive substitution into the equations of motion, seems to modify the dispersion relations in a manner similar to (3). However, that would be a misleading conclusion. As in the case of the 3-rd rank operator just discussed, one needs to separate it from all lower-rank interactions. In other words, one needs to subtract all possible $g^{\mu\nu}$ and $\epsilon^{\mu\nu\rho\sigma}$ traces of this term, and then substitute it into the equations of motion. It turns out that this operator is completely expressible in terms
of its $\epsilon^{\mu\nu\rho\sigma}$-trace, which coincides with the operator $C^{\mu\nu\rho}$:

$$F_{\mu\nu} \partial_\lambda F_{\rho\sigma} =$$

$$- \frac{1}{5} \epsilon_{\mu\nu\rho\chi} \tilde{F}^{\chi\lambda} \partial_\lambda F_{\rho\sigma} + \frac{1}{5} \epsilon_{\mu\sigma\chi} \tilde{F}^{\chi\lambda} \partial_\lambda F_{\rho\nu} + \frac{1}{5} \epsilon_{\rho\sigma\chi} \tilde{F}^{\chi\lambda} \partial_\lambda F_{\mu\nu} - \frac{1}{5} \epsilon_{\rho\sigma\chi} \tilde{F}^{\chi\lambda} \partial_\lambda F_{\mu\rho} \quad [6]$$

This relation shows that it is not possible to bring the rank five operator to an irreducible form, and consequently there is no dimension 5 LV interaction contracted with irreducible rank five tensor. We conclude that the only possible LV operator in QED is $C^{\mu\nu\rho}$. All these arguments straightforwardly extend to a non-abelian gauge field.

**B. Matter Sector of QED**

In contrast to what we have seen in the gauge sector, the LV terms in the matter sector of QED have much wider variety. The reason for that is that the operators can be formed both by using covariant derivatives $D_\mu$ and by inserting gamma matrices.

In order to make the enumeration of operators more systematic, we use Young tableaux, see Appendix B. Omitting the details, we show the result for the LV operators in the matter sector,

$$\mathcal{L}_{\text{QED}}^{\text{matter}} =$$

$$\left[ c_1^{\mu} \cdot \bar{\psi} \gamma^\lambda F_{\mu\lambda} \psi^+ \right] + \left[ c_2^{\mu} \cdot \bar{\psi} \gamma^\lambda \gamma^5 F_{\mu\lambda} \psi^- \right] + \tilde{c}_1^{\mu} \cdot \bar{\psi} \gamma^\lambda F_{\mu\lambda} \psi^+ + \tilde{c}_2^{\mu} \cdot \bar{\psi} \gamma^\lambda \gamma^5 \tilde{F}_{\mu\lambda} \psi^- +$$

$$+ f_1^{\mu\nu} \cdot \bar{\psi} F_{\mu\nu} \psi^- + f_2^{\mu\nu} \cdot \bar{\psi} F_{\mu\nu} \gamma^5 \psi^- + h_1^{\mu\nu} \cdot \bar{\psi} [D_\mu D_\nu] \psi^+ + h_2^{\mu\nu} \cdot \bar{\psi} [D_\mu D_\nu] \gamma^5 \psi^+ +$$

$$+ C_1^{\mu\nu\rho} \cdot \bar{\psi} \gamma_{(\mu} D_\nu D_\rho) \psi^- + C_2^{\mu\nu\rho} \cdot \bar{\psi} \gamma_{(\mu} \gamma^5 D_\nu D_\rho) \psi^+ +$$

$$+ D_1^{\mu\nu\rho} \cdot \bar{\psi} \gamma_{(\mu} F_{\nu\rho)} \psi^+ + D_2^{\mu\nu\rho} \cdot \bar{\psi} \gamma_{(\mu} F_{\nu\rho)} \gamma^5 \psi^- +$$

$$+ E_1^{\mu\nu\rho\lambda} \cdot \bar{\psi} \gamma_{\sigma_{(\mu}} D_{(\nu} D_{\lambda)} \psi^- + E_2^{\mu\nu\rho\lambda} \cdot \bar{\psi} \gamma_{\sigma_{(\mu}} F_{\rho(\nu)} \psi^+ + E_3^{\mu\nu\rho\lambda} \cdot \bar{\psi} \gamma_{\sigma_{\rho}} F_{\phi(\lambda)\psi^+} +$$

$$+ E_4^{\mu\nu\rho\lambda} \cdot \bar{\psi} \gamma_{(\mu} \gamma^5 D_{(\nu} D_{\lambda)} \psi^- + 2 \sigma_{\nu\rho} D_{(\mu} D_{\lambda)} \psi^+ .$$

In this formula, + and − superscripts refer to the parity of the corresponding LV term under the charge conjugation. We stress again that all structures shown here assume their coefficients to be irreducible tensors of the corresponding rank. Square brackets over the
first two operators, \( c_1^\mu \) and \( c_2^\mu \), indicate that these two terms vanish upon the use of EOM, but we list them for the reason they become nontrivial in the non-abelian case.

We would like to make a side note on the symmetrizations in the interactions in (4) and in subsequent formulae. We take the field operators to have certain symmetries (dictated by the corresponding Young tableaux), while their Wilson coefficients to be just traceless tensors. Equivalently, one could have cast all symmetrizations onto the Wilson coefficients, e.g.

\[
E_1^{\mu\nu\rho\lambda} \bar{\psi} \sigma_{\mu\nu} D_\rho D_\lambda \psi \rightarrow E_1^{(\mu)(\nu)(\rho)(\lambda)} \bar{\psi} \sigma_{\mu\nu} D_\rho D_\lambda \psi,
\]

or just imply \( E_1^{\mu\nu\rho\lambda} \) to obey the corresponding symmetries:

\[
E_1^{\mu\nu\rho\lambda} \cdot \bar{\psi} \sigma_{\mu\nu} D_\rho D_\lambda \psi.\]

We emphasize that this is only a matter of notation, and choose to expose the symmetry properties of tensors via explicit symmetrizations on the Lorentz indices of the field operators.

C. 1-loop RG coefficients

If the violation of Lorentz invariance is a true UV phenomenon, one has to evaluate the operators down to the IR scale, where the majority of tests is performed. For this purpose, we study the renormalization group (RG) equations for operators (3) and (4). The RG running brings about the change in the magnitude of Wilson coefficients and mixing of different operators.

Due to a rather large number of LV operators, one might expect that this mixings can be rather complicated. However, the two reasons, namely the discrete symmetries and irreducibility of the Lorentz tensors, reduce this mixing to a minimum. The charge conjugation symmetry, which is an exact symmetry in QED, prevents the mixing of \( C \)-odd and \( C \)-even operators. The irreducibility of the background tensors dictates that any tensor of higher rank will not mix with a tensor of a lower rank. Thus, only operators of the same rank can admix to each other.

A brief examination of (4) reveals that \( \tilde{c}_1^\mu \) cannot mix with \( \tilde{c}_2^\mu \) due to \( C \)-parity. Similarly, \( f_{1,2}^{\mu\nu} \) cannot admix to \( h_{1,2}^{\mu\nu} \), but they can mix within each other. At the level of rank three tensors, the photon operator (3) is even under charge conjugation and therefore it can mix only with the \( C_2^{\mu\nu\rho} \) operator.

As we have admitted generic tensor structures to the theory we need to ensure that the latter is free of quadratic divergencies. It is obvious that quadratically divergent operators must necessarily couple to a vector background, as there are no dimension three structures
which would be CPT-odd and contracted with a tensor background simultaneously. In our list \( \tilde{c}_1^{\mu} \), only the \( \tilde{c}_1^{\mu} \) term generates quadratically divergent corrections to LV dimension three operators. The result of explicit computation gives the following set of RG equations:

\[
\frac{d}{dt} \tilde{c}_1^{\mu} \text{ formally } = -\frac{13e^2}{96\pi^2} \tilde{c}_1^{\mu}
\]
\[
\frac{d}{dt} \bar{f}_{1,2}^{\mu\nu} = -\frac{7e^2}{24\pi^2} f_{1,2}^{\mu\nu} + \frac{7e^2}{48\pi^2} \bar{f}_{2,1}^{\mu\nu}
\]
\[
\frac{d}{dt} \tilde{c}_1^{\mu\nu\rho} = \frac{25e^2}{48\pi^2} C_1^{\mu\nu\rho}
\]
\[
\frac{d}{dt} D_1^{\mu\nu\rho} = -\frac{e^2}{16\pi^2} D_1^{\mu\nu\rho}
\]
\[
\frac{d}{dt} E_1^{\kappa\mu\nu\rho} = \frac{13e^2}{24\pi^2} E_1^{\kappa\mu\nu\rho}
\]
\[
\frac{d}{dt} E_2^{\kappa\mu\nu\rho} = \frac{e^2}{12\pi^2} E_2^{\kappa\mu\nu\rho} + \frac{d}{dt} \tilde{f}_{1,2}^{\kappa\mu\nu\rho} \equiv \frac{1}{2} \epsilon^{\mu\nu\rho\sigma}(f_{1,2})_{\rho\sigma}
\]
\[
\frac{d}{dt} \tilde{c}_2^{\mu} = \frac{e^2}{32\pi^2} \tilde{c}_2^{\mu}
\]
\[
\frac{d}{dt} h_{1,2}^{\mu\nu} = \frac{e^2}{2\pi^2} h_{1,2}^{\mu\nu}
\]
\[
\frac{d}{dt} C_2^{\mu\nu\rho} = \frac{25e^2}{48\pi^2} C_2^{\mu\nu\rho} - \frac{5e^2}{48\pi^2} C_2^{\mu\nu\rho}
\]
\[
\frac{d}{dt} C_2^{\mu\nu\rho} = \frac{e^2}{48\pi^2} C_2^{\mu\nu\rho} - \frac{e^2}{6\pi^2} C_2^{\mu\nu\rho}
\]
\[
\frac{d}{dt} D_2^{\mu\nu\rho} = \frac{5e^2}{48\pi^2} D_2^{\mu\nu\rho}
\]
\[
\frac{d}{dt} E_3^{\kappa\mu\nu\rho} = \frac{e^2}{3\pi^2} E_3^{\kappa\mu\nu\rho}
\]
\[
\frac{d}{dt} E_4^{\kappa\mu\nu\rho} = \frac{e^2}{8\pi^2} E_4^{\kappa\mu\nu\rho}
\]

Here we have introduced \( \tilde{f}_{1,2}^{\mu\nu\rho} \equiv \frac{1}{2} \epsilon^{\mu\nu\rho\sigma}(f_{1,2})_{\rho\sigma} \). As anticipated, most operators renormalize independently. It is also clear that one can easily form the linear combinations of LV interactions that are eigenvectors of one-loop RG equations.

\[\text{III. CLASSIFICATION OF OPERATORS OF DIMENSION V IN THE STANDARD MODEL}\]

In the Standard Model, the set of LV operators is more complicated, due to the wider gauge group. Since the LV physics in our approach is associated with the UV scale, the LV operators must respect all the symmetries which are present at that scale. Although the UV physics and its symmetries are not known, it is quite natural to require that LV interactions be invariant under \( SU_C(3) \otimes SU_L(2) \otimes U(1) \). Clearly the existence of families causes coefficients of all LV interactions in the matter sector \( \text{(4)} \) to be matrices in the flavor space \( \text{[1]} \). Furthermore, the presence of the Higgs sector creates new possibilities for LV interactions. However, there is one simplification arising from intrinsic chirality of SM spinors, which together with gauge invariance would essentially prohibit all \( E^{\kappa\mu\nu\rho} \) operators at dimension five level. In the rest of this section, we present our results for LV operators in different sectors of the SM.
A. Operators in the Gauge Sector of the Standard Model

As in the QED case, the gauge sector is the simplest since we already know that the only possible LV gauge structure is (3). Thus we replicate this structure for the three gauge groups of the SM:

$$\mathcal{L}_{\text{gauge}}^{\text{SM}} = C_{\text{U}(1)}^{\mu\nu\rho} \cdot F_{\mu\lambda} \partial_\nu \tilde{F}^\lambda_\rho + C_{\text{SU}_L(2)}^{\mu\nu\rho} \cdot \text{tr} W_{\mu\lambda} D_\nu \tilde{W}^\lambda_\rho + C_{\text{SU}_C(3)}^{\mu\nu\rho} \cdot \text{tr} G_{\mu\lambda} D_\nu \tilde{G}^\lambda_\rho.$$  (5)

B. Matter Sector of the Standard Model

Although the matter sector of the Standard Model is more diverse than that of QED, the number of “types” of operators is smaller. Due to chirality of both leptons and quarks, the structures with an even number of $\gamma$-matrices in (4) are not SU$_L$(2)-gauge invariant. That greatly simplifies the structure of the LV Lagrangian, as one can only have operators with an odd number of gamma matrices. In the resulting Lagrangian we have to abandon the C-parity eigenstates, (4) and list operators using $V - A$ and $V + A$ combinations of Dirac matrices.

Since in QED

$$D_{[\mu} D_{\nu]} = i e F_{\mu\nu},$$  (6)

the first two terms in (4) actually vanish on the equations of motion. However, with the exception of right-handed leptons, the covariant derivatives for SM field contain different gauge potentials. For example, for quarks one has

$$D_{[\mu} D_{\nu]} = i Y g' F_{\mu\nu} + i g W_{\mu\nu} + i g_3 G_{\mu\nu},$$  (7)

where $Y$ is the hypercharge of the quark. The use of equations of motion allows then to express one of the operators $\overline{Q} \gamma^\lambda F_{\mu\lambda} Q$, $\overline{Q} \gamma^\lambda W_{\mu\lambda} Q$ and $\overline{Q} \gamma^\lambda G_{\mu\lambda} Q$ in terms of the other two but cannot eliminate such operators completely. Taking this into account, in the quark
sector one obtains the following LV interactions:

\[
\mathcal{L}_{\text{SM}}^{\text{quark}} = \\
C_{Q,1}^\mu \cdot \overline{Q} \gamma^\lambda F_{\mu \lambda} Q + C_{Q,3}^\mu \cdot \overline{Q} \gamma^\lambda W_{\mu \lambda} Q + C_u^\mu \cdot \overline{u} \gamma^\lambda L_{\mu \lambda} u + C_d^\mu \cdot \overline{d} \gamma^\lambda L_{\mu \lambda} d + \\
+ \overline{c}_{Q,1}^\mu \cdot \overline{Q} \gamma^\lambda \tilde{F}_{\mu \lambda} Q + \overline{c}_{Q,2}^\mu \cdot \overline{Q} \gamma^\lambda \tilde{W}_{\mu \lambda} Q + \overline{c}_{Q,3}^\mu \cdot \overline{Q} \gamma^\lambda \tilde{G}_{\mu \lambda} Q + \\
+ C_{u,1}^\mu \cdot \overline{u} \gamma^\lambda \tilde{F}_{\mu \lambda} u + C_{u,3}^\mu \cdot \overline{u} \gamma^\lambda \tilde{G}_{\mu \lambda} u + \overline{c}_{d,1}^\mu \cdot \overline{d} \gamma^\lambda \tilde{F}_{\mu \lambda} d + \overline{c}_{d,3}^\mu \cdot \overline{d} \gamma^\lambda \tilde{G}_{\mu \lambda} d + \\
+ C_{\mu}^{u,\nu} \cdot \overline{Q} \gamma(\mu D_{\nu} D_{\rho}) Q + C_{\mu}^{u,\nu} \cdot \overline{\nu} \gamma(\mu D_{\nu} D_{\rho}) \nu + C_{d}^{\mu,\nu} \cdot \overline{\nu} \gamma(\mu G_{\rho}) \nu \nu + \\
+ D_{\mu,1}^{u,\nu} \cdot \overline{d} \gamma(\mu F_{\rho}) \nu d + D_{\mu,3}^{u,\nu} \cdot \overline{d} \gamma(\mu G_{\rho}) \nu d.
\]

Here all coefficients are assumed to be Hermitian matrices in the flavor space, e.g.

\[
C_{Q,1}^\mu \cdot \overline{Q} \gamma^\lambda F_{\mu \lambda} Q \equiv (C_{Q,1}^\mu)_{ik} \cdot \overline{Q}_i \gamma^\lambda F_{\mu \lambda} Q_k.
\]

Similarly, LV interactions in the lepton sector of the Standard Model take the form:

\[
\mathcal{L}_{\text{SM}}^{\text{lepton}} = \\
C_{\nu}^\mu \cdot \overline{\nu} \gamma^\lambda L_{\mu \lambda} L + C_{\nu,1}^\mu \cdot \overline{\nu} \gamma^\lambda \tilde{F}_{\mu \lambda} L + C_{\nu,2}^\mu \cdot \overline{\nu} \gamma^\lambda \tilde{W}_{\mu \lambda} L + \\
+ C_{\nu,3}^\mu \cdot \overline{\nu} \gamma^\lambda \tilde{G}_{\mu \lambda} L + \\
+ C_{\nu}^{\mu,\nu} \cdot \overline{\nu} \gamma(\mu D_{\nu} D_{\rho}) \nu \nu + C_{\nu}^{\mu,\nu} \cdot \overline{\nu} \gamma(\mu G_{\rho}) \nu \nu + \\
+ D_{\nu,1}^{u,\nu} \cdot \overline{\nu} \gamma(\mu F_{\rho}) \nu \nu + D_{\nu,3}^{u,\nu} \cdot \overline{\nu} \gamma(\mu G_{\rho}) \nu \nu.
\]

As one can see, the absence of strong interactions for leptons makes (9) more compact compared to (8).

### C. Higgs sector

The scalar sector of the SM in its minimal form contains one electroweak doublet, which also admits LV extensions. All LV operators with the use of the Higgs field can be further
subdivided into two groups. The first are interactions built of the Higgs field and derivatives:

\[ \mathcal{L}_{\text{Higgs–gauge}} = \]

\[ l^\mu \cdot i \dot{H} \gamma_\mu H + k^{\mu \nu \rho} \cdot i \dot{H} D_\mu D_\rho \partial_\nu H + m_1^\mu \cdot i \dot{H} F_\mu \partial_\nu \partial_\rho + m_2^\mu \cdot i \dot{H} W_\mu \partial_\nu \partial_\rho \partial_\rho \partial_\nu \partial_\mu + \text{h.c.} \]  

\[ + n_1^{\mu \nu \rho} \cdot i \dot{H} F_{\nu (\mu} D_{\rho)} H + n_2^{\mu \nu \rho} \cdot i \dot{H} W_{\nu (\mu} D_{\rho)} H + \text{h.c.} \]  

(10)

The second group contains all possible LV extensions of interaction of Higgs field and fermions. This group is somewhat larger and includes higher-rank structures. The following are the operators involving quarks:

\[ \mathcal{L}_{\text{Higgs–quark}} = h^\mu_{QQ} \cdot \overline{Q} \gamma_\mu H \gamma_\mu Q + \]

\[ + p_{QQ}^\mu \cdot \overline{Q} \gamma_\mu Q \gamma_\mu H \gamma_\mu H + p_{uu}^\mu \cdot \overline{u} \gamma_\mu u \gamma_\mu H \gamma_\mu H + p_{dd}^\mu \cdot \overline{d} \gamma_\mu d \gamma_\mu H \gamma_\mu H + \text{h.c.} \]  

\[ + q_{Qd}^{(1) \mu} \cdot \overline{Q} d D_\mu H + q_{Qu}^{(1) \mu} \cdot \overline{Q} u D_\mu H^* + \text{h.c.} \]  

\[ + q_{Qd}^{(2) \nu} \cdot \overline{Q} \sigma^{\mu \nu \rho} D_\mu D_\rho H + q_{Qu}^{(2) \nu} \cdot \overline{Q} \sigma^{\mu \nu \rho} D_\mu D_\rho H^* + \text{h.c.} \]  

\[ + r_{Qd}^{(1) \mu \nu \rho} \cdot \overline{Q} D_{(\mu} \sigma_{\nu)} D_{\rho) H} + r_{Qu}^{(2) \mu \nu \rho} \cdot \overline{Q} D_{(\mu} \sigma_{\nu)} D_{\rho) H^*} + \text{h.c.} \]  

(11)

where \( \epsilon H^* \) is the charge conjugate of the Higgs field. One also has the similar set of operators for interaction of the Higgs with leptons:

\[ \mathcal{L}_{\text{Higgs–lepton}} = h_{LL}^\mu \cdot \overline{L} H \gamma_\mu L \gamma_\mu H + p_{LL}^\mu \cdot \overline{L} \gamma_\mu L \gamma_\mu L \gamma_\mu H + p_{ee}^\mu \cdot \overline{e} \gamma_\mu e \gamma_\mu H \]

\[ + q_{Le}^{(1) \mu} \cdot \overline{L} e D_\mu H + q_{Le}^{(2) \nu} \cdot \overline{L} \sigma^{\mu \nu \rho} e D_\mu H + \text{h.c.} \]  

(12)

\[ + r_{Le}^{(1) \mu \nu \rho} \cdot \overline{L} D_{(\mu} \sigma_{\nu)} e D_{\rho) H} + r_{Le}^{(2) \mu \nu \rho} \cdot \overline{L} \sigma_{(\mu \nu)} e D_{(\rho \mu} H + \text{h.c.} \]

\[ + \varsigma^{\mu \nu} \cdot (H^T L)^T \sigma_{\mu \nu} (H^T L) + \text{h.c.} \]

The last term in the Higgs-lepton sector, which couples to matrix \( \varsigma^{\mu \nu} \) antisymmetric in the flavor space, is unusual. It is special in a sense that it does not have analogues in other sectors, or in lower dimensions as it violates the lepton number by two units.

This completes the list of the dimension V Lorentz-violating operators in the Standard Model. The set of operators in the Standard Model appears to be much wider than that in QED due to the diversity of fields and interactions. Loop corrections are expected to intermix
the operators in an even more complicated way. Clearly, there are many operators that give rise to dimension 3 LV interaction with quadratically divergent coefficients. Although, as indicated earlier, studying renormalization of interactions is beneficial for refining constraints on LV, we are not setting the goal to derive all one-loop RG equations similarly to what we have done in QED.

On the other hand, of particular interest are the rank three absolutely symmetric operators $C^\mu\nu\rho(X)$ and $\kappa^\mu\nu\rho$ that modify the dispersion relations for the SM particles. For these operators, we calculate the one-loop RG equations and present the results in Appendix A.

**IV. OVERVIEW OF LV PHENOMENOLOGY AT DIMENSION 5 LEVEL**

We now discuss typical limits on sensitivity to LV dimension 5 operators, which can be inferred from experimental tests of Lorentz symmetry in laboratory, astrophysical observations and data on neutrino oscillations. Given the abundance of non-minimal interactions we have derived in the last section, it would be useful to separate them in several classes and deduce a typical experimental sensitivity within each class.

Many of the constraints result from laboratory experiments or astrophysical observations at energies much lower than the weak scale. The Higgs boson, $W$ and $Z$ bosons and heavy SM fermions do not propagate at these energies and can be integrated out. Such integration at tree level provides new operators of higher mass dimensions which we are not considering here. One should keep in mind, however, that loop effects admix LV operators with heavy particles to the light quark and lepton LV operators of the same dimension. Such (typically one-loop) corrections include the logarithmic mixing under the RG running, as well as the finite threshold corrections. Therefore, the bounds discussed below contain an intrinsic sensitivity to LV interactions involving Higgs and weak bosons.

For most phenomenological applications it is useful to rewrite the LV Lagrangian at the normalization scale of around 1 GeV, the borderline of applicability for the quark-gluon description. At this scale it is useful to abandon chiral fermions and combine the left- and right-handed fields into full Dirac spinors as well as split the SU$_L$(2) doublets.

For practical reasons, one can also pass to the mass basis of the flavor matrices, as it
facilitates the decoupling of heavy quarks:

\[
c_Q, c_u \rightarrow c_u \Bigg|_{\text{below EW}} = \frac{1}{2} \left( W_u^\dagger c_u W_u + U_u^\dagger c_Q U_u \right)
\]

\[
\rightarrow c_{u,5} \Bigg|_{\text{below EW}} = \frac{1}{2} \left( W_u^\dagger c_u W_u - U_u^\dagger c_Q U_u \right)
\]

\[\cdots\cdots\]

\[u_L \rightarrow U_u u_L, ~ u_R \rightarrow W_u u_R, ~ d_L \rightarrow U_d d_L, ~ d_R \rightarrow W_d d_R.\]

For consistency of the effective theory, we need to ensure that the operators that we have introduced do not transmute into lower dimensions, and thereby not develop quadratic divergencies. We can formulate certain criteria to ensure that operators cannot induce lower dimensional interactions:

- **Tensor structure.** Since in the Standard Model there are no CPT-odd dimension three operators of rank higher than one, any LV structure that is coupled to an irreducible tensor (which is not a vector) is unconditionally protected from developing quadratic divergencies.

- **Supersymmetry.** In the supersymmetric Standard Model, dimension three SV operators do not exist at all. Therefore, as long as the theory is considered above the supersymmetry breaking scale, those operators which fall into supermultiplets of the LV MSSM, are protected [16]. By cancellation of loop contributions due to superpartners, the quadratic divergencies turn into logarithmic ones if supersymmetry is exact. It turns out that there is only one type of such operators

\[
\mathcal{L}_{\text{SUSY}} = \bar{c}_{\text{SUSY},Q} \left( Y_Q g^\prime Q^\gamma \tilde{F}_{\mu\lambda} Q + g Q^\gamma \tilde{W}_{\mu\lambda} Q + g_3 Q^\gamma \tilde{G}_{\mu\lambda} Q \right) + \cdots
\]

(here, \(Y_Q\) refers to the hypercharge of the left quark doublet) which, in the case of quarks, must form a certain linear combination to be part of a supermultiplet. Linear combinations orthogonal to the above one are not supersymmetric and therefore not protected. When the supersymmetry is broken, the above operators are allowed to induce quadratic divergencies, which will be stabilized at the supersymmetry breaking scale.

- **\(T\)-invariance.** Since in the Standard Model one needs multiple loops to flip \(T\)-parity
of flavor-diagonal interactions, one can conclude that the operators which do not have dimension three counterparts with the same T-parity, are protected.

- **Lepton-number violation.** There are no dimension three LV operators compatible with the Standard Model which would violate the lepton number. We know that there is only one \( \Delta L = 2 \) operator of dimension five — \( \zeta^{\mu\nu} \), which therefore is protected against developing quadratic divergencies.

The operators for which the above criteria do not apply, have no reason to be protected, and therefore will intermix with lower-dimensional interactions in a UV-sensitive way. We call such operators “unprotected”. Such interactions are dangerous and we will exclude them from our low energy effective theory. Using T-parity it is easy to show that the dangerous operators in the quark and lepton sectors (Eqs. (8) and (9)) are the ones coupled to the dual field strengths

\[
L_{\text{divgt}} = \tilde{c}_{Q,1} \cdot \overline{Q} \gamma^\lambda \tilde{F}^\mu_{\mu \lambda} Q + \tilde{c}_{Q,3} \cdot \overline{Q} \gamma^\lambda \tilde{G}^\mu_{\mu \lambda} Q + \tilde{c}_{q,1} \cdot \overline{q} \gamma^\lambda \tilde{F}^\mu_{\mu \lambda} q + \tilde{c}_{q,3} \cdot \overline{q} \gamma^\lambda \tilde{G}^\mu_{\mu \lambda} q \\
+ \tilde{c}_{L,1} \cdot \overline{T} \gamma^\lambda \tilde{F}^\mu_{\mu \lambda} L + \tilde{c}_e \cdot \overline{e} \gamma^\lambda \tilde{F}^\mu_{\mu \lambda} e + L_{\text{divgt}}^{\text{Higgs}},
\]

(15)

where we have abbreviated \( q = u, d \). In the Higgs sector, the following operators in Eqs. (10)-(12) are unprotected from transmuting into lower dimensional terms:

\[
L_{\text{divgt}}^{\text{Higgs}} = b^\mu \cdot i H^\dagger H \cdot H^\dagger D_{\mu} H + \tilde{m}_1^\mu \cdot i \bar{H}^\dagger \tilde{F}^\mu_{\mu \lambda} \bar{H} + \tilde{m}_2^\mu \cdot i \bar{H}^\dagger \tilde{W}^\mu_{\lambda \lambda} \bar{H} + \\
+ h_{QQ}^\mu \cdot \overline{Q} H \gamma_{\mu} H^\dagger Q + h_{LL}^\mu \cdot \overline{T} H \gamma_{\mu} H^\dagger L + \\
+ p_{QQ}^\mu \cdot \overline{Q} \gamma_\mu Q \cdot H^\dagger H + p_{uu}^\mu \cdot \overline{u} \gamma_\mu u \cdot H^\dagger H + p_{dd}^\mu \cdot \overline{d} \gamma_\mu d \cdot H^\dagger H + \\
+ p_{LL}^\mu \cdot \overline{T} \gamma_\mu L \cdot H^\dagger H + p_{ee}^\mu \cdot \overline{e} \gamma_\mu e \cdot H^\dagger H \\
+ q_{Qd}^{(2)\nu} \cdot \overline{Q} \sigma^{\mu\nu} d \cdot D_{\nu} H + q_{Qu}^{(2)\nu} \cdot \overline{Q} \sigma^{\mu\nu} u \cdot D_{\nu} e H + q_{Le}^{(2)\nu} \cdot \overline{L} \sigma^{\mu\nu} e \cdot D_{\nu} H + \text{h.c.}
\]

(16)

Using the quadratic divergence of the loop corrections generated by operators (15), one can estimate the strength of the naturalness constraints resulting from experimental limits on dimension 3 LV terms [18]:

\[
|b^\mu| = (\text{loop factor}) \Lambda^2 |\tilde{c}^\mu| \lesssim 10^{-29} \text{ GeV}.
\]

(17)

Even in the very conservative assumption about the UV cutoff, e.g. \( \Lambda = \Lambda_{\text{weak}} \), this limit would make futile any efforts of detecting interactions (15) directly. We again note that
even though certain linear combinations (14) might be protected by supersymmetry, below
the supersymmetry breaking scale they are unprotected and therefore subject to constraints
(17).
From this moment, we concentrate only on UV-safe operators and list the following
effective interactions in the quark sector at the scale of 1 GeV:

\[
L_{\text{quark}}^{\text{SM 1 GeV}} =
\frac{1}{\sqrt{2}} q^\mu \gamma^\nu D_\mu \gamma^\rho \gamma^5 D_\rho q
+ \frac{1}{\sqrt{2}} \bar{q} \gamma^\nu (\mu D_\nu D_\rho) \gamma^5 q
+ \frac{1}{\sqrt{2}} \bar{q} \gamma^\nu (\mu D_\nu D_\rho) \gamma^5 q
+ \frac{1}{\sqrt{2}} \bar{q} \gamma^\nu (\mu D_\nu D_\rho) \gamma^5 q
+ \frac{1}{\sqrt{2}} \bar{q} \gamma^\nu (\mu D_\nu D_\rho) \gamma^5 q
\]

and similarly in the lepton sector:

\[
L_{\text{lepton}}^{\text{SM 1 GeV}} =
\frac{1}{\sqrt{2}} l^\mu \gamma^\nu D_\mu \gamma^\rho \gamma^5 D_\rho \psi
+ \frac{1}{\sqrt{2}} \bar{l} \gamma^\nu (\mu D_\nu D_\rho) \gamma^5 \psi
+ \frac{1}{\sqrt{2}} \bar{l} \gamma^\nu (\mu D_\nu D_\rho) \gamma^5 \psi
+ \frac{1}{\sqrt{2}} \bar{l} \gamma^\nu (\mu D_\nu D_\rho) \gamma^5 \psi
\]

Passing to the gauge sector, we refer to Eq. (5). At low energies the LV Lagrangian in
the gauge sector takes the form

\[
L_{\text{gauge}}^{\text{SM 1 GeV}} =
\frac{1}{\sqrt{2}} C_{\mu \nu \rho}^{\text{emp}} \cdot F_{\mu \lambda} \gamma_{\nu} \gamma_{\rho} \gamma^5 F_{\mu \lambda}
+ \frac{1}{\sqrt{2}} C_{\mu \nu \rho}^{\text{SU}(3)} \cdot \gamma_{\nu} \gamma_{\rho} \gamma^5 \psi
+ \frac{1}{\sqrt{2}} C_{\mu \nu \rho}^{\text{SU}(2)} \cdot \gamma_{\nu} \gamma_{\rho} \gamma^5 \psi
+ \frac{1}{\sqrt{2}} C_{\mu \nu \rho}^{\text{U(1)}} \cdot \gamma_{\nu} \gamma_{\rho} \gamma^5 \psi
\]

Here, the electromagnetic operator \( C_{\mu \nu \rho}^{\text{emp}} \) emerges as a linear combination of the LV tensors
from the U(1) and SU_L(2) sectors:

\[
C_{\mu \nu \rho}^{\text{emp}} \bigg|_{M_\text{W}} =
C_{\mu \nu \rho}^{\text{U(1)}} \bigg|_{M_\text{W}} \cos^2 \theta_W
+ C_{\mu \nu \rho}^{\text{SU}(3)} \bigg|_{M_\text{W}} \sin^2 \theta_W
\]

In the Higgs sector, in Eqs. (10)-(12) many “protected” terms involve a space-time deriva-
tive acting on the Higgs field. Below the EW scale, where Higgs does not propagate, such
terms do not contribute. One is left with the following low-energy interactions:

\[
L_{\text{Higgs-induced}}^{\text{SM 1 GeV}} =
\frac{v}{\sqrt{2}} q^\mu \gamma^\nu D_\nu \gamma^5 \psi q
+ \frac{v}{\sqrt{2}} \bar{q} \gamma^\nu \gamma^5 \psi D_\nu \gamma^5 \psi
+ \text{h.c.}
\]

\[
+ \frac{v^2}{2} \bar{\psi} \gamma^\nu \gamma^5 \sigma_{\mu \nu} \psi
+ \text{h.c.}
\]

where \( q = u, d \) and \( \psi = e, \nu \). The last operator in Eq. (20) violates the lepton number by
two, and in the low-energy theory can only exist for neutrinos.

The interactions in (18)-(19) can be divided into two groups. The first group is formed by the operators which modify dispersion relations and grow with energy [11], which we call the **UV-enhanced operators**. The second group, correspondingly, hosts all other structures, which we designate as “soft” LV interactions (see Table I). We now outline the main sources of constraints applicable to these groups of low-energy LV interactions.

*Ultra-high energy cosmic rays.* The existence of high-energy cosmic rays of energies $E_{\text{max}} \sim 10^{12}$ GeV puts stringent bounds on UV-enhanced operators in certain sectors of the Standard Model, depending on relative magnitude of LV sources in these sectors [18]. Renormalization group equations (see Appendix A) then spread these limits on the other sectors. The UV-enhanced operators modify the dispersion relations of the particles, and this would allow the nucleons in the cosmic rays to emit photons or light leptons, and therefore efficiently lose all their energy before reaching the Earth. The fact of observation of high-energy cosmic rays sets typical constraints on UV-enhanced LV of the order of $10^{-33-34}$ GeV$^{-1}$. It would be fair to say that not all “corners” of the parameter space of UV-enhanced operators are covered by these limits. For example, sufficiently strong LV in the up quark sector would allow protons in the cosmic rays to decay into $\Delta^{++}$ which could become stable at high energies [18].

*Precision experiments.* Astrophysical constraints are not applicable to soft LV interactions, since the latter do not modify propagation of particles. For this type of interactions
the bounds from low-energy precision experiments are in order. The strongest limits occur when an operator induces the interaction of nuclear spin with the nuclear electric or chromomagnetic field. One finds that the operators $D_{q}^{\mu\nu\rho}$, $D_{qg}^{\mu\nu\rho}$ and $r_{q}^{\mu\nu\rho}$, when averaged over the nucleus give an effective interaction

$$\mathcal{L}_{\text{eff}} \propto \nabla(\mu \sigma_{\nu})_{\rho} N,$$

multiplied by a coefficient $\sim \Lambda_{\text{QCD}}$ which can be estimated by a naive dimensional counting of the nucleon matrix element [19]. For a non-relativistic nucleus this induces the interaction of the nuclear spin with the external preferred directions. Known limits [20] on interaction of nuclear spin with external directions allow one to estimate typical constraints on operators

$$|D_{qg}^{0k}|, \quad |D_{qg,5}^{ijk}| < 10^{-30} \text{ GeV}^{-1}, \quad |r_{q}^{0k}| < 10^{-31} \text{ GeV}^{-1}.$$

The limits on the interactions $D_{q}^{\mu\nu\rho}$, $D_{qg}^{\mu\nu\rho}$ and $c_{q}^{\mu}$ are less strong by a factor of $\alpha$ due to the suppression of the nuclear electric field relative to the chromomagnetic field strength. In constraining the leptonic operators $D_{l}^{\mu\nu\rho}$ and $r_{e}^{\mu\nu\rho}$ one loses the advantage of using the strong internal nuclear fields, and the corresponding bounds are weakened by the ratio of the characteristic atomic energy scale to the nuclear energy scale $p_{\text{at}}/p_{\text{nuc}} \sim \alpha m_{e}/\Lambda_{\text{QCD}}$.

**Electric dipole moments.** The operators $D_{q,5}^{\mu\nu\rho}$, $D_{gq,5}^{\mu\nu\rho}$ and $D_{l,5}^{\mu\nu\rho}$, written in terms of low-energy effective Hamiltonian possess the signature of Electric Dipole Moment interactions. Averaged over the nucleus, the first two induce nuclear EDMs, for which the existing limits can be used to constrain the amount of Lorentz violation [21]:

$$|c_{q,5}^{0}|, \quad |D_{q,5}^{0k}| \lesssim 10^{-12} \text{ GeV}^{-1}.$$

The electron operator $D_{l,5}^{\mu\nu\rho}$ applied to paramagnetic atoms induces the electric dipole moment of the atom, and this way a bound of the similar strength is obtained [21].

**Neutrino phenomenology.** The operator $\varsigma_{\mu}^{\nu} \cdot \nu T \sigma_{\mu\nu}\nu$ is capable of changing the patterns of neutrino oscillations. Constraints from reactor and atmospheric neutrino oscillation data can be used [22] to limit various flavor components of $\varsigma_{\mu}^{\nu}$. In the best case scenario, the sensitivity of the neutrino oscillation experiments could provide the limits at the level of

$$|\varsigma_{\mu}^{\nu}| \lesssim 10^{-23-24} \text{ GeV}^{-1}.$$

We comment that the constraints on LV operators displayed in this section do not generically restrict all the components of corresponding LV tensors. However, a customary argument applies, that the “unobservable” parts of the tensors could induce the detectable
effects due to the Lorentz boost caused by motion of the Earth relative to the Galaxy, and so cannot exceed the observable components by more than $O(10^3)$.

V. CONCLUSION

We have presented a systematic Lorentz-violating extension of Quantum Electrodynamics and the Standard Model with all possible dimension five operators. Quantum Electrodynamics is the simplest phenomenological example to consider. At the level of mass dimension five, QED admits a plethora of LV interactions, parametrized by background vectors and tensors, most of which are concentrated in the matter sector. We found the one-loop logarithmic renormalization group equations for the QED LV operators, and identified one operator that has quadratic sensitivity to the UV-cutoff.

Extending QED to full Standard Model, we list all possible LV interactions satisfying the criteria of the effective field theory given in the Introduction. Certainly, the wider gauge group and the diversity of field content lead to a sufficiently broader set of LV structures than in QED, although the gauge sector remains very simple. However, one quickly runs into the problem of dimensional transmutation into dimension three operators via quadratic divergencies, which can easily invalidate the distinction between operators of different dimensions. One therefore is naturally lead to an additional requirement of the absence of uncontrollable divergencies in a consistent effective theory. We identify broad classes of LV operators that are protected against dimensional transmutations by a variety of different mechanisms. These mechanisms include the protection by the irreducibility of the LV spurion tensor structures, supersymmetry, $T$-invariance, and the lepton number conservation.

The protected operators of the effective low-energy theory can be divided into several qualitatively different groups. The first group of interactions directly affects the propagation of particles by introducing a (species-dependent) “speed-of-light”. We call such operators UV-enhanced, since they introduce corrections to the dispersion relations which grow with the energy. The bounds on UV-enhanced operators are well-known to be of the order $10^{-33–34}$ GeV$^{-1}$ and come from astrophysical observations. Although these bounds are well studied, we calculate the renormalization group equations that govern the logarithmic evolution of these operators over the energy scales, which can be helpful in strengthening the bounds on operators involving heavy fields.
All the other protected operators present in our effective theory do not grow with energies of propagating particles, and we call them soft LV interactions. In general strong astrophysical constraints are not applicable to such operators. Limits of the order $10^{-28-30} \text{ GeV}^{-1}$ on several classes of such operators can be deduced from clock comparison types of laboratory experiments, and are still sufficiently tight. Among less constrained type of operators are those that violate lepton number by two units, and $T$-odd operators that are limited only by the electric dipole moment constraints.

The strength of the analysis performed in this paper is in its generality. Indeed, if one day a theory of quantum gravity or any other UV-sensitive theory would reach the stage of predicting the low-energy LV phenomenology, such predictions can be readily compared with the set of operators derived in this work, and in addition can be tested for consistency with respect to their UV behavior at the loop level.
Appendix A: RG EQUATIONS FOR DIMENSION FIVE OPERATORS WHICH MODIFY DISPERSION RELATIONS

We list one-loop RG equations for LV operators which modify propagation of particles, i.e. those which couple to absolutely symmetric tensors. Although the set of such interactions in the Standard Model is not diverse, the equations appear to be complicated. The notations for the operators are introduced in section III B. All operators bear three indices $\mu$, $\nu$ and $\rho$ which we omit for brevity.

In what follows, $Y_X$ are the hypercharges of the corresponding particles; $\lambda_X$ are Yukawa coupling matrices for species $X$; $g'$, $g$ and $g_3$ are correspondingly the U(1), SU$_L$(2) and SU$_C$(3) gauge coupling constants; we introduce

$$
\alpha_1 = \frac{5/3 N_g + 1/8}{6\pi^2},
$$
$$
\alpha_2 = -\frac{19 - 8N_g}{48\pi^2},
$$
$$
\alpha_3 = -\frac{5 - 4/3 N_g}{8\pi^2},
$$

which are the gauge wavefunction renormalization coefficients for the Standard Model, where $N_g = 3$ is the number of generations; we also use the following notations:

$$
N_W = 2 \quad \text{(dim fund SU(2))} \quad T_W = \frac{N_W^2 - 1}{2N_W},
$$
$$
N_S = 3 \quad \text{(dim fund SU(3))} \quad T_S = \frac{N_S^2 - 1}{2N_S}.
$$

Below we present the RG equations for UV-enhanced LV operators above the EW symmetry breaking scale. The Wilson coefficients are assumed to be flavor matrices given in the
gauge basis.

\[
\begin{align*}
\frac{d}{dt} C_L &= \frac{25}{48\pi^2} \left( g^2 Y_L^2 + g^2 T_W \right) C_L + \frac{1}{32\pi^2} \left\{ \lambda_e^\dagger \lambda_e, C_L \right\} \\
&+ \frac{5g^2}{48\pi^2} Y_L^2 C_{\text{U(1)}} \cdot 1_{\text{flavor}} + \frac{5g^2}{48\pi^2} T_W C_{\text{SU}_L(2)} \cdot 1_{\text{flavor}} \\
&- \frac{1}{96\pi^2} \lambda_e C_e \lambda_e^\dagger - \frac{1}{64\pi^2} \lambda_e^\dagger \lambda_e \cdot \kappa \\
\frac{d}{dt} C_Q &= \frac{25}{48\pi^2} \left( g^2 Y_Q^2 + g^2 T_W + g_3^2 T_S \right) C_Q + \frac{1}{32\pi^2} \left\{ \lambda_d^\dagger \lambda_d + \lambda_u^\dagger \lambda_u, C_Q \right\} \\
&+ \frac{5g^2}{48\pi^2} Y_Q^2 C_{\text{U(1)}} \cdot 1_{\text{flavor}} + \frac{5g^2}{48\pi^2} T_W C_{\text{SU}_L(2)} \cdot 1_{\text{flavor}} + \frac{5g_3^2}{48\pi^2} T_S C_{\text{SU}_C(3)} \cdot 1_{\text{flavor}} \\
&- \frac{1}{96\pi^2} \left( \lambda_d C_d \lambda_d^\dagger + \lambda_u C_u \lambda_u^\dagger \right) - \frac{1}{64\pi^2} \left( \lambda_d^\dagger \lambda_d - \lambda_u^\dagger \lambda_u \right) \cdot \kappa \\
\frac{d}{dt} C_e &= \frac{25g^2}{48\pi^2} Y_e^2 C_e + \frac{1}{16\pi^2} \left\{ \lambda_e^\dagger \lambda_e, C_e \right\} \\
&- \frac{5g^2}{48\pi^2} Y_e^2 C_{\text{U(1)}} \cdot 1_{\text{flavor}} - \frac{1}{48\pi^2} \lambda_C \lambda_e \lambda_e^\dagger + \frac{1}{32\pi^2} \lambda_e^\dagger \lambda_e \cdot \kappa \\
\frac{d}{dt} C_u &= \frac{25}{48\pi^2} \left( g^2 Y_u^2 + g_3^2 T_S \right) C_u + \frac{1}{16\pi^2} \left\{ \lambda_u^\dagger \lambda_u, C_u \right\} \\
&- \frac{5g^2}{48\pi^2} Y_u^2 C_{\text{U(1)}} \cdot 1_{\text{flavor}} - \frac{5g_3^2}{48\pi^2} T_S C_{\text{SU}_C(3)} \cdot 1_{\text{flavor}} \\
&- \frac{1}{48\pi^2} \lambda_u^\dagger C_Q \lambda_u - \frac{1}{32\pi^2} \lambda_u^\dagger \lambda_u \cdot \kappa \\
\frac{d}{dt} C_d &= \frac{25}{48\pi^2} \left( g^2 Y_d^2 + g_3^2 T_S \right) C_d + \frac{1}{16\pi^2} \left\{ \lambda_d^\dagger \lambda_d, C_d \right\} \\
&- \frac{5g^2}{48\pi^2} Y_d^2 C_{\text{U(1)}} \cdot 1_{\text{flavor}} - \frac{5g_3^2}{48\pi^2} T_S C_{\text{SU}_C(3)} \cdot 1_{\text{flavor}} \\
&- \frac{1}{48\pi^2} \lambda_d^\dagger C_Q \lambda_d + \frac{1}{32\pi^2} \lambda_d^\dagger \lambda_d \cdot \kappa
\end{align*}
\]
The analogous RG equations for the gauge LV operators take the form:

\[
\frac{d}{dt} C_{U(1)} = -\frac{g^2}{48\pi^2} \text{tr} \left( Y_L^2 C_L + N_S Y_Q^2 C_Q - Y_e^2 C_e - N_S Y_u^2 C_u - N_S Y_d^2 C_d \right) + \alpha_1 g^2 C_{U(1)}
\]

\[
\frac{d}{dt} C_{SU(2)} = -\frac{g^2}{192\pi^2} \text{tr} \left( C_L + N_S C_Q \right) + \left( \alpha_2 g^2 + \frac{7}{12\pi^2} N_W g^2 \right) \cdot C_{SU(2)}
\]

\[
\frac{d}{dt} C_{SU(3)} = -\frac{g^2}{192\pi^2} \text{tr} \left( 2C_Q - C_u - C_d \right) + \left( \alpha_3 g^2 + \frac{7}{12\pi^2} N_S g^2 \right) \cdot C_{SU(3)}
\]

(A2)

\[
\frac{d}{dt} \kappa = \frac{5}{12\pi^2} \left[(g')^2 Y^2_H + g^2 T_W \right] \cdot \kappa
\]

\[
+ \frac{1}{8\pi^2} \text{tr} \left( \lambda_e \lambda_e^\dagger + N_S \lambda_u \lambda_u^\dagger + N_S \lambda_d \lambda_d^\dagger \right) \cdot \kappa
\]

\[
- \frac{1}{12\pi^2} \text{tr} \left( N_S \lambda_d^\dagger C_Q \lambda_d + \lambda_d^\dagger C_L \lambda_e - N_S \lambda_u^\dagger C_Q \lambda_u - N_S \lambda_d C_d \lambda_d^\dagger - \lambda_e C_e \lambda_e^\dagger + N_S \lambda_d C_u \lambda_u^\dagger \right) \right).
\]

We observe that mixing of RG operators is quite noticeable between all sectors of the Standard Model.

The RG equations for UV-enhanced LV interactions below the EW scale read as:

\[
\frac{d}{dt} C_{\nu} = 0
\]

\[
\frac{d}{dt} C_{\nu,5} = 0
\]

\[
\frac{d}{dt} C_e = \frac{25e^2}{48\pi^2} \cdot C_e
\]

\[
\frac{d}{dt} C_{e,5} = \frac{25e^2}{48\pi^2} \cdot C_{e,5} + \frac{5e^2}{48\pi^2} \cdot C_{EM} \cdot 1_{\text{flavor}}
\]

\[
\frac{d}{dt} C_u = \frac{25}{48\pi^2} \left( q_u^2 e^2 + T_S g_3^2 \right) \cdot C_u
\]

\[
\frac{d}{dt} C_{u,5} = \frac{25}{48\pi^2} \left( q_u^2 e^2 + T_S g_3^2 \right) \cdot C_{u,5} + \frac{5}{48\pi^2} \left( q_u^2 e^2 C_{EM} + g_3^2 T_S C_{SU(3)} \right) \cdot 1_{\text{flavor}}
\]

\[
\frac{d}{dt} C_d = \frac{25}{48\pi^2} \left( q_d^2 e^2 + T_S g_3^2 \right) \cdot C_d
\]

\[
\frac{d}{dt} C_{d,5} = \frac{25}{48\pi^2} \left( q_d^2 e^2 + T_S g_3^2 \right) \cdot C_{d,5} + \frac{5}{48\pi^2} \left( q_d^2 e^2 C_{EM} + g_3^2 T_S C_{SU(3)} \right) \cdot 1_{\text{flavor}}
\]

for matter operators, and

\[
\frac{d}{dt} C_{EM} = \frac{e^2}{48\pi^2} \text{tr} \left( C_{e,5} + N_S q_u^2 C_{u,5} + N_S q_d^2 C_{d,5} \right) + \alpha_{EM} \cdot C_{EM}
\]

\[
\frac{d}{dt} C_{SU(3)} = \frac{g_3^2}{96\pi^2} \text{tr} \left( C_{u,5} + C_{d,5} \right) + \left( \alpha_3 + \frac{7}{12\pi^2} N_S \right) g_3^2 \cdot C_{SU(3)}
\]

(A4)
for gauge LV interactions. Here the flavor matrices of the Wilson coefficients are given in the mass basis. Below the EW scale we have done an obvious transition to

\[
\frac{C_L + C_e}{2} \equiv C_e|_{\text{EW}}, \quad \frac{C_L - C_e}{2} \equiv C_{e,5}|_{\text{EW}}, \quad \text{etc}.
\]

We have denoted the electric charges by \( q_X \), and introduced

\[
\alpha_{\text{EM}} = \frac{1}{6\pi^2} \times \sum_{\text{species}} q_i^2,
\]

which is the wavefunction renormalization coefficient for the electromagnetic field. Here the sum runs over all species existing at the given scale \( \mu \).

Although the RG mixing in Eqs. (A3), (A4) is not very considerable, we again emphasize that the operators effectively mix above the EW scale, see Eqs. (A1), (A2).
Appendix B: YOUNG TABLEAUX AND IRREDUCIBLE TENSORS OF THE LORENTZ GROUP

To build irreducible tensors of an arbitrary rank one can use the Young tableaux. We describe here a recipe how to expand a tensor of a specific rank into its irreducible components*. In the text we most extensively exploit rank three tensors, which we here now use as a non-trivial but rather simple example.

For a tensor of rank $r$ one builds all possible numbered Young tableaux consisting of $r$ boxes. For each tableau one builds an irreducible component by (anti)symmetrizing its indices as described below. After that, to make a component truly irreducible, one has to subtract from it all its $g^{\mu\nu}$-traces.

For each numbered diagram, one builds a tensor such that each number corresponds to an index (e.g. for $T^{\mu\nu\rho}$, one could identify $1 \to \mu, 2 \to \nu, 3 \to \rho$). Indices whose numbers form horizontal rows in the diagram are symmetrized. Indices which form vertical columns are antisymmetrized. Symmetrization always occurs with respect to the name of the index. Antisymmetrization is always done with respect to the position of the index (in this case the number not always corresponds to one and the same index).

As an illustration to what have been said, we build the diagrams for a tensor $T^{\mu\nu\rho}$. One finds four different Young diagrams which can be built out of three boxes:

$$
\begin{array}{c}
1 & 2 & 3 \\
\begin{array}{c}
1 \\
2 \\
3 \\
\end{array}
\end{array}
\hspace{1cm}
\begin{array}{c}
1 \\
2 \\
3 \\
\end{array}
\hspace{1cm}
\begin{array}{c}
1 & 2 \\
3 \\
\end{array}
\hspace{1cm}
\begin{array}{c}
1 \\
2 & 3 \\
\end{array}
\hspace{1cm}
(B1)
\end{array}
$$

The first diagram corresponds to an absolutely symmetric component of the tensor:

$$S^{\mu\nu\rho} = T^{(\mu\nu\rho)} = T^{\mu\nu\rho} + T^{\nu\rho\mu} + T^{\rho\mu\nu} + T^{\mu\rho\nu} + T^{\rho\nu\mu} + T^{\nu\mu\rho}. $$

The second diagram is the absolutely antisymmetric component:

$$A^{\mu\nu\rho} = T^{[\mu\nu\rho]} = T^{\mu\nu\rho} + T^{\nu\rho\mu} + T^{\rho\mu\nu} - T^{\mu\rho\nu} - T^{\rho\nu\mu} - T^{\nu\mu\rho}. $$

The two “corner” diagrams generate, correspondingly,

$$T_1^{\mu\nu\rho} = T^{\mu\nu\rho} - T^{\rho\nu\mu} + T^{\nu\mu\rho} - T^{\rho\mu\nu},$$

* For more details, the reader is referred to [23].
and

\[
\begin{array}{|c|c|c|}
\hline
1 & 3 \\
2 & & \\
\hline
\end{array} \quad \rightarrow \quad T_{2}^{\mu \nu \rho} = T_{1}^{\mu \nu \rho} - T^{\nu \mu \rho} + T^{\mu \nu \rho} - T^{\nu \rho \mu}.
\]

All four components of (B1) (weighed by appropriate coefficients) sum into the original tensor \(T^{\mu \nu \rho}\):

\[
T^{\mu \nu \rho} = \frac{1}{3!} \left( S^{\mu \nu \rho} + A^{\mu \nu \rho} + 2T_{1}^{\mu \nu \rho} + 2T_{2}^{\mu \nu \rho} \right).
\]  (B2)

The last step to perform is subtract from each component all traces obtained by contraction of any two indices which are not antisymmetrized (contraction of antisymmetrized indices is trivial). The solution can be sought by means of a tensor of a rank less by two:

\[
T_{i}^{\mu \nu \rho} = T_{i}^{\mu \nu \rho} - a_{i}^{\rho} \epsilon_{\mu \nu \rho} + a_{i}^{\mu} \epsilon_{\mu \nu \rho} + \ldots,
\]  (B3)

where \(T_{i}^{\mu \nu \rho}\) is the \(i\)-the component obtained from the corresponding Young tableau. The trace part in the r.h.s. of (B3) should possess the same symmetries as \(T_{i}^{\mu \nu \rho}\) so as to promote these symmetries to the l.h.s. Contracting any two indices in equation (B3) and requiring the result to vanish one can obtain the explicit expression for the trace \(a_{i}^{\rho}\). For the tensors listed in Eq. (B2) one obtains:

\[
S_{(irr)}^{\mu \nu \rho} = S^{\mu \nu \rho} - \frac{1}{6} \left( b^{\mu} \epsilon_{\nu \rho \mu} + b^{\nu} \epsilon_{\rho \mu \nu} + b^{\rho} \epsilon_{\mu \nu \rho} \right), \quad b^{\mu} = S^{\mu \lambda \lambda},
\]

\[
A_{(irr)}^{\mu \nu \rho} = A^{\mu \nu \rho},
\]

\[
T_{1 (irr)}^{\mu \nu \rho} = T_{1}^{\mu \nu \rho} - \frac{1}{3} \left( a_{(1)}^{(\mu)} \epsilon_{\nu \rho \mu} - 2 a_{(1)}^{\rho} \epsilon_{\mu \nu \rho} \right), \quad a_{(1)}^{\mu} = T^{\mu \lambda \lambda} - T^{\lambda \mu \lambda},
\]

\[
T_{2 (irr)}^{\mu \nu \rho} = T_{2}^{\mu \nu \rho} - \frac{1}{3} \left( a_{(2)}^{(\mu)} \epsilon_{\nu \rho \mu} - 2 a_{(2)}^{\rho} \epsilon_{\mu \nu \rho} \right), \quad a_{(2)}^{\mu} = T^{\mu \lambda \lambda} - T^{\lambda \mu \lambda}.
\]

These arguments are easily generalized to tensors of arbitrary ranks.
