ABSTRACT

References to accelerators and accelerator technology in the technical literature from July 1954 through June 1957 are listed in Section I, the bibliography. Most of the references are taken from Nuclear Science Abstracts, Chemical Abstracts, Physics Abstracts, and Electrical Engineering Abstracts.

In Section II, accelerator installations throughout the world are listed together with the types of particles accelerated and the energy and other characteristics of the machines.

INTRODUCTION

This bibliography supplements the following compilations:

1. E. Thomas, P. Mittelman, and H. H. Goldsmith, Particle Accelerators; Bibliography and List of High-Energy Installations, BNL-L-101 and AECU-31 (July 1, 1948).
2. Bonnie E. Cushman, Bibliography of Particle Accelerators July 1948 to December 1950, UCRL-1238 (March 1951).
3. Sergey Shewchuck, Bibliography of Particle Accelerators January to December 1951, UCRL-1951 (September 1952).
4. F. E. Frost and J. M. Putnam, Particle Accelerators, I. Bibliography. II. List of High-Energy Installations, UCRL-2672 (November 16, 1954).

For this compilation, the literature searched includes Nuclear Science Abstracts, Chemical Abstracts, Physics Abstracts (Science Abstracts A), and Electrical Engineering Abstracts (Science Abstracts B) for the period from July 1954 through June 1957. Also included are certain articles and references not derived from the above abstracts. References are arranged in groups according to the accelerator classification and are arranged alphabetically within the accelerator group by author's surname. An author index listing all authors is provided, and each bibliography entry is numbered to facilitate searching for the work of individual authors with the aid of the author index. Articles by companies, societies, organizations, and institutions are arranged alphabetically by source in the author index.

The abbreviations used here include NSA for Nuclear Science Abstracts, CA for Chemical Abstracts, SA A for Physics Abstracts, and SA B for Electrical Engineering Abstracts. Typical examples of the notation system used in this report to describe entries in these publications are:

<u>UCRL-8050 Notation</u>	<u>Explanation</u>
NSA <u>8</u> , 3873 (54)	This is Abstract 3873 of Volume 8 of Nuclear Science Abstracts issued in 1954.
CA <u>48</u> , 9821e (54)	This Abstract is located in Section e of Column 9821 in Volume 48 of Chemical Abstracts for 1954.
SA <u>A57</u> , 6671 (54)	This is Abstract 6671 of Volume 57 of Physics Abstracts (Science Abstracts A) issued in 1954.
SA <u>B57</u> , 6671 (54)	This is Abstract 6671 of Volume 57 of Electrical Engineering Abstracts (Science Abstracts B) issued in 1954.
G. B.	This entry has been noted directly from the literature by the author of this bibliography.

In the preparation of this bibliography every effort has been made to include pertinent publications in the correct categories. Articles of a general nature in the accelerator field are grouped under the heading General. Those articles that discuss more than one type of machine are included in each of the appropriate accelerator groups. Publications that could not readily be classified in any of the aforementioned groups are listed under Miscellaneous.

The author will appreciate notification of duplications, omissions, or other shortcomings in this bibliography.

PARTICLE ACCELERATORS

II. LIST OF ACCELERATOR INSTALLATIONS

Gerald A. Behman

Radiation Laboratory
University of California
Berkeley, California

January 1, 1958

INTRODUCTION

This list is intended to include data on all accelerators throughout the world and supersedes similar lists by Bonnie E. Cushman in UCRL-1238 (March, 1951), by Sergey Shewchuck in UCRL-1951 (September, 1952), and by Frederick E. Frost and Jane M. Putnam in UCRL-2672 (November, 1954).

Data presented here have been acquired in most instances by direct response to a questionnaire sent by the author to the individual installations or, in the case of some foreign countries, to the scientific attachés of the various embassies. In a few cases, it was necessary to acquire the data indirectly through the technical literature or by reference to manufacturers' data.

Of the 411 questionnaires sent out, 224 went to installations in the United States, while 187 went to other countries. Replies were received from 89% of the installations polled in the United States, and from 74% of the foreign installations. Questionnaires submitted to Argentina, Brazil, Chile, China, Mexico, Rumania, and Turkey were not answered.

A time interval of ten months was arbitrarily set for response to the questionnaire. In some instances, not all of the desired information was furnished on the returned questionnaire; these cases are indicated in the list by n. a. (not available).

For rapid and ready reference, the information is classified, first, according to the type of accelerator and, second, according to the address of the installation. Each accelerator group is grossly separated into those machines located in the United States and those located elsewhere in the world.

The general types of accelerators included are direct-current (dc) machines, induction machines, and resonance accelerators. The dc machines comprise cascade rectifiers (Cockcroft-Walton), electrostatic generators (Van de Graaff), and certain transformer-rectifier combinations. The primary example of an accelerator operating on the principle of induction is the betatron. Resonance accelerators include both traveling- and standing-wave linear accelerators as well as magnetic accelerators of the cyclotron or synchrotron type. In this survey, the category cyclotron includes continuous-wave (CW) and frequency-modulated (FM) machines. The synchrotron group includes proton, electron, and fixed-field alternating-gradient (FFAG) machines.

For the convenience of the reader, the distribution of these machines throughout the world is summarized by type of accelerator and country in Table I. The distribution of types of establishments having accelerators in the United States is analyzed in Table II according to type of machine and primary activity of the organization.

Every effort has been made to avoid duplication or omission of information. The author will appreciate notification of such errors.

ACKNOWLEDGMENTS

The author sincerely appreciates the aid and encouragement that he has received from many sources during the preparation of this bibliography and accelerator list. The aid of various members of the Technical Information Division staff has been invaluable. Special thanks are due to Dr. Edwin M. McMillan for suggesting the accelerator classification system used here.

This work was performed under the auspices of the United States Atomic Energy Commission.

Corrections

Certain fixed-field alternating-gradient (FFAG) accelerators were included in the synchrotron group in the recently published list by this author.¹ McMillan has pointed out that, under the classification system suggested by him for this list, all FFAG accelerators belong in the cyclotron class because the field does not vary as a function of time.¹² Accordingly, the FFAG machines listed for the Midwestern Universities Research Association, Madison, Wis. should be included in the cyclotron group in this list.

In the classification system used, two general types of cyclotrons were indicated. These are continuous-wave (CW) and frequency-modulated (FM) machines. It should be noted that the FM class of cyclotrons may be referred to alternatively as synchrocyclotrons.

The dimensions of the larger of two Van de Graaff machines at Argonne National Laboratory, Lemont, Illinois were listed incorrectly. This machine has a 15-ft accelerating tube, can accelerate protons, deuterons, or alpha particles, and has a maximum energy of 4.5 Mev.²

D.C. machines listed at the Centre d'Etudes Nucléaires, Grenoble, France and at the Laboratoire de Physique Atomique et Moléculaire, Collège de France, Paris are Felici-type accelerators rather than Van de Graaff generators.⁷ As contrasted with the belt system of charge transport of the Van de Graaff machines, the Felici machine uses a dielectric cylinder which rotates about a slightly conducting glass stator. Thin steel strips charge and discharge the rotor as a result of induction of metallic inductors within the glass cylinder. For improved efficiency, the machine usually operates under a high pressure.¹³

The proper location of the betatron listed for the Knolls Atomic Power Laboratory is General Engineering Laboratory, General Electric Company, Schenectady, N. Y.³

¹²Edwin M. McMillan, Lawrence Radiation Laboratory, private communication (1958).

¹³Emile Labin, Electromechanical Design 2, No. 11, 24 (1958).

The 4-Mev Van de Graaff machine and 32-Mev proton linac formerly at University of California in Berkeley have been moved to the University of Southern California at Los Angeles, California.

Acknowledgments

The author is deeply grateful to the scientists of various countries who provided the new and revised information published here. Thanks are due Dr. Edwin McMillan for helpful suggestions and to other members of the staff of the Lawrence Radiation Laboratory for their aid.
