(Received 12 August 2009; published 9 November 2009)

Considering the present limits on their masses from the Tevatron experiments, the fourth-family quarks are expected to have masses larger than the top quark. Because of their expected large masses, they could have different dynamics than the third-family quarks of the standard model. The resonant production of the fourth-family up-type quark $t'$ has been studied via the anomalous production subprocess $gg \rightarrow t'$ (where $q_i = u, c$) at the LHC, with center-of-mass energies of 10 TeV and 14 TeV. The signatures of such a process are discussed within the standard model decay modes. The sensitivity to the anomalous coupling $\kappa/\Lambda = 0.1$ TeV$^{-1}$ can be reached at $\sqrt{s} = 10$ TeV and $L_{\text{int}} = 100$ pb$^{-1}$.

I. INTRODUCTION

The number of fermion families in nature, the pattern of fermion masses, and the mixing angles in the quark/lepton sectors are unresolved issues in the standard model (SM). The repetition of quark and lepton families remains a mystery as part of the flavor problem. On theoretical grounds, the asymptotic freedom in quantum chromodynamics imposes an indirect bound on the number of quark flavors, which should be less than 18. The electroweak precision measurements done by the CERN LEP experiments imply that the number of light neutrinos ($m_\nu < 45$ GeV) is equal to 3 [1]. The most recent analyses indicate that an additional family of heavy fermions is not inconsistent with the precision electroweak data at the available energies [2–8]. Indeed, the presence of three or four fermion families is equally consistent with the electroweak precision data; moreover the four-family scenario is favored if the Higgs boson is heavier than 200 GeV [4].

The fourth-family quarks have the Yukawa couplings running with the scale, and these couplings reach the Landau pole at just a little above 1 TeV. The discovery of the fourth-family quarks could reveal a dynamical symmetry breaking and mass formation via fermion condensation through strong interactions. The fourth family may play an important role in our understanding of the flavor structure of the SM. The flavor democracy is one of the main motivations for the existence of the fourth-family fermions [9]. Another motivation for the fourth family comes from the charge-spin unification [10]. Additional fermions can also be accommodated in many models beyond the SM [11]. A recent review of the fourth SM family, including the theoretical and experimental aspects, can be found in [12].

A lower limit on the mass of the fourth-family quark $b'$ is $m_{b'} > 325$ GeV from Tevatron experiments [13], whereas the upper limit from partial wave unitarity is about 1 TeV. The recent results from the Collider Detector at Fermilab (CDF) exclude the $t'$ mass below 311 GeV at 95% C.L. using the data of 2.8 fb$^{-1}$ [14].

The tree-level flavor changing processes occur only via the charged current interactions in the SM. The first two rows of the Cabibbo-Kobayashi-Maskawa (CKM) matrix [15] are in good agreement with the unitary condition. The data for the number of $b$ jets in top quark pair production at the Tevatron constrain the ratio $R = |V_{tb}|^2/|\sum_{q} V_{tq}|^2$, which is closely related to $V_{tb}$ if the CKM is unitary. The direct constraints on $|V_{tb}|$ come from the single production of top quarks at the Tevatron. From the average cross section $\sigma = 3.94 \pm 0.88$ pb, the lower limit $|V_{tb}| > 0.78$ at 95% C.L. is given by the CDF and D0 Collaborations [16]. A measurement of the single top production cross section that is smaller than the SM prediction would imply $V_{tb} < 1$ or evidence of extra families of quarks mixed with the third generation. A flavor extension of the SM, with a

†yildiz@mail.cern.ch
‡ocakir@mail.cern.ch
§gokhan.une@cern.ch
fourth generation of quarks, leads to an extended CKM matrix which could have \( V_{tb} \) smaller than 1. In the extended model, the strongest constraint on \( V_{tb} \) comes from the ratio \( R_b = \Gamma(Z \to b\bar{b})/\Gamma(Z \to \text{hadrons}) \), with \( R > 0.9 \) for \( m_t \cong 1.5 m_t \). For an extra up-type quark \( t' \) and another extra down-type quark \( b' \), the \( 4 \times 4 \) matrix is unitary, for which any \( 3 \times 3 \) submatrix becomes nonunitary as long as these new quarks mix with quarks of three families. Hence, the new flavor changing neutral currents (FCNC) could appear without violating the existing bounds from current experimental measurements [17,18].

The existence of a fourth generation of quarks would have interesting implications. Taking into account the current bounds on the mass of the fourth-family quarks [1], the anomalous interactions can emerge in the fourth family. Furthermore, extra families will yield an essential enhancement in the Higgs boson production at the LHC [19]. The single production [20,21] mechanism of fourth-family quarks will be suppressed by the elements \( (t',b') \) of the \( 4 \times 4 \) CKM matrix. The fourth-family quark pairs can already be produced at the LHC at an initial center-of-mass energy of \( \sqrt{s} = 10 \text{ TeV} \) and an initial luminosity of \( L = 10^{31} \text{ cm}^{-2} \text{ s}^{-1} \). At the nominal center-of-mass energy \( \sqrt{s} = 14 \text{ TeV} \), the initial luminosity will be \( 10^{33} \text{ cm}^{-2} \text{ s}^{-1} \) which will later increase to \( 10^{34} \text{ cm}^{-2} \text{ s}^{-1} \) corresponding to 10 and 100 fb\(^{-1}\) per year, respectively.

In this work, we present an analysis of the anomalous resonant production of \( t' \) quarks at the LHC. Here, we assume the case \( t' \) decays through SM dominated channel (via charged currents) in which the magnitude of \( V_{tb} \) is important, leading to a final state \( W^\pm b_{\text{jet}} \) for \( t' \) anomalous production. A fast simulation is performed for the detector effects on the signal and background. Any observations of the invariant mass peak in the interval 300–800 GeV with the final state containing \( W^\pm b_{\text{jet}} \) can be interpreted as the signal for \( t' \) anomalous resonant production.

II. FOURTH-FAMILY QUARK INTERACTIONS

Fourth-family quarks can couple to charged weak currents by \( W^\pm \) boson exchange, neutral weak currents by \( Z^0 \) boson exchange, electromagnetic currents by photon exchange, and strong color currents by gluon exchange. We include the fourth-family quarks in the enlarged framework (primed) of the SM. The interaction Lagrangian is given by

\[
L' = -g_{\gamma} \sum_{Q_i} \bar{Q}_i \gamma^\mu Q_i A_\mu - g_s \sum_{Q_i} \bar{Q}_i T^a_\mu \gamma^\mu Q_i G^a_\mu
- \frac{g_{\gamma}}{2 \cos \theta_w \sin \theta_w} \sum_{Q_i} \bar{Q}_i \gamma^\mu (g_\gamma - g^\mu A^\gamma) Q_i Z^\mu
- \frac{g_{\gamma}}{2 \sqrt{2} \sin \theta_w} \sum_{Q_i} V_{ij} \bar{Q}_i \gamma^\mu (1 - \gamma^5) q_j W^\pm + \text{H.c.,}
\]

where \( g_{\gamma} \) is the electromagnetic coupling constant and \( g_s \) is the strong coupling constant. The vector fields \( A_\mu, G_\mu, Z_\mu, \) and \( W^\pm_\mu \) denote the photon, gluon, \( Z^0 \) boson, and \( W^\pm \) boson, respectively. \( Q_\times \) is the electric charge of fourth-family quarks, and \( T^a \) are the Gell-Mann matrices. The \( g_V \) and \( g_A \) are the couplings for vector and axial-vector neutral currents. Finally, the CKM matrix elements \( V_{ij} \) are expressed as \( V = V^V V^D \). The corresponding \( 4 \times 4 \) CKM matrix is given by

\[
V = \left( \begin{array}{cccc}
V_{ud} & V_{us} & V_{ub} & V_{ub'} \\
V_{cd} & V_{cs} & V_{cb} & V_{cb'} \\
V_{td} & V_{ts} & V_{tb} & V_{tb'} \\
V_{f'd} & V_{f's} & V_{f'b} & V_{f'b'}
\end{array} \right).
\] (2)

The magnitude of the \( 3 \times 3 \) CKM matrix elements is determined from the low energy and high energy experiments: these are \( |V_{ud}| = 0.974 18 \pm 0.000 27 \), \( |V_{ct}| = 0.2255 \pm 0.0019 \), \( |V_{ub}| = 0.003 93 \pm 0.000 36 \), \( |V_{cd}| = 0.230 \pm 0.011 \), \( |V_{cs}| = 1.04 \pm 0.06 \), \( |V_{cb}| = 0.0412 \pm 0.0011 \), \( |V_{td}| = 0.0081 \pm 0.0006 \), \( |V_{ts}| = 0.0387 \pm 0.0023 \) (assuming \( |V_{tb}| \) is equal to unity) [1], and single top production yields \( |V_{tb}| = 0.91 \pm 0.11 \) at 95% C.L. [22]. In the fourth-family case, these elements should be less than their mean values. For a \( 4 \times 4 \) CKM matrix, from the unitarity requirement, the first three rows are calculated as \( |V_{ub'}|^2 \leq 0.00011 \), \( |V_{cb'}|^2 \leq 0.13519 \), and \( |V_{tb'}|^2 \leq 0.29524 \). For the first three columns one calculates the values \( |V_{f'd}|^2 \leq 0.00199 \), \( |V_{f's}|^2 \leq 0.13395 \), and \( |V_{f'b'}|^2 \leq 0.17019 \). We see that there is a loose constraint for the mixing between third- and fourth-family quarks. Recent studies [23] have shown that CKM mixing between third-family quarks and fourth-family quarks can be as large as the Cabibbo mixing. The electroweak oblique parameters \( (S, T) \) are within the experimentally allowed regions if the fourth-family quarks have a mass splitting \( |m_t - m_b| \approx 50 \text{ GeV} \) [4]. In the case \( m_t = m_b + 50 \text{ GeV} \), the \( t' \) quark decay into \( b'W^+ \) would be accessible, and this has some effects on the \( t' \) branchings depending on the CKM4 parametrization. When \( m_t = m_b - 50 \text{ GeV} \), we expect two-body decay for the \( t' \) quark. In this study, we consider mainly the latter option. Inspired by the Wolfenstein parametrization of the \( 3 \times 3 \) CKM matrix, we could simply consider a parametrization for the fourth row and fourth column of the \( 4 \times 4 \) CKM as \( |V_{q'q}| = |V_{q'q}| = A_{ij} \lambda^{n-1} \), where \( A_{ij} \) can be optimized for the quark flavors \( q_i \) and \( q_j \); \( n \) is the family number and \( \lambda \) is a constant.

We consider the decay width of the \( t' \) quark through \( t' \to W^+ q \), including the final state quark mass; we find

\[
\Gamma(Q' \to Wq) = \frac{1}{16} \frac{1}{\sin^2 \theta_w m_{q'}^2} \lambda^2 \lambda \sqrt{\lambda},
\] (3)
\[ \lambda_r = 1 + \frac{m_W^2}{m_{Q_r}^2} + \frac{m_{Q_r}^4}{m_{Q_r}^4} - 2m_W^2 + 2m_{Q_r}^2 - 2m_{Q_r}^2/m_{Q_r}^4 \]

\[ \lambda_W = 1 + \frac{m_W^2}{M_Q^2} - 2m_{Q_r}^2 + \frac{m_{Q_r}^4}{m_{Q_r}^4} + 2m_{Q_r}^4/m_{Q_r}^4 \]

To calculate the decay width numerically, we assume three parametrizations—PI, PII, and PIII—for the fourth-family mixing matrix elements. For the PI parametrization, we assume the constant values \( |V_{Qq}| = |V_{Qq}| = 0.01 \), PI contains dynamical parametrization \( V_{Qq} = |V_{Qq}| \approx \lambda^{4-n} \) with a preferred value of \( \lambda = 0.1 \), and the PIII parametrization assumes maximal mixings \( |V_{Qq}| \approx 0.063 \), \( |V_{Qq}| \approx 0.46 \), \( |V_{Qq}| \approx 0.47 \), \( |V_{Qq}| \approx 0.044 \), \( |V_{Qq}| \approx 0.46 \), \( |V_{Qq}| \approx 0.47 \), \( |V_{Qq}| \approx 0.47 \), \( |V_{Qq}| \approx 0.47 \), \( |V_{Qq}| \approx 0.47 \), \( |V_{Qq}| \approx 0.47 \), \( |V_{Qq}| \approx 0.47 \), and \( |V_{Qq}| \approx 0.47 \), given by Ref. [24], corresponding to the case of one sigma deviation from the mean values of \( |V_{Qq}|^2 \) and \( |V_{Qq}|^2 \).

The flavor changing neutral current interactions are known to be absent at tree level in the SM. However, the fourth-family quarks, being heavier than the top quark, could have different dynamics than other quarks; they can couple to the FCNC currents, leading to an enhancement in the resonance processes at the LHC. Moreover, the arguments for the anomalous interactions of the top quark given in [25] are more valid for \( t' \) and \( b' \) quarks. The effective Lagrangian for the anomalous interactions among the fourth-family quarks \( t' \) and \( b' \), ordinary quarks \( q \), and the neutral gauge bosons \( V = \gamma, Z, g \) can be written explicitly:

\[
L_a = \sum_{q_j = u,c,t} \frac{\kappa^2_{q_j}}{\Lambda} Q_{q_j} g_{\mu
u} \frac{\sigma_{\mu\nu}}{2} q_{q_j} F_{\mu\nu} + \sum_{q_j = u,c,t} \frac{\kappa^2_{q_j}}{\Lambda} g_{\mu \nu} \frac{\sigma_{\mu\nu}}{2} q_{q_j} Z_{\mu\nu} + \sum_{q_j = u,c,t} \frac{\kappa^2_{q_j}}{\Lambda} g_{\mu \nu} \frac{\sigma_{\mu\nu}}{2} q_{q_j} G_{\mu\nu} + \text{H.c.}
\]

where \( F_{\mu\nu}, Z_{\mu\nu}, \text{and } G_{\mu\nu} \) are the field strength tensors of the gauge bosons; \( \sigma_{\mu\nu} = i(\gamma_\mu \gamma_\nu - \gamma_\nu \gamma_\mu)/2 \); \( \lambda_\alpha \) are the Gell-Mann matrices; \( Q_{q_j} \) is the electric charge of the quark \( q_j \); \( g_e, g_Z, \text{and } g_s \) are the electromagnetic, neutral weak, and strong coupling constants, respectively. \( g_z = g_e / \cos \theta_w \sin \theta_w \), where \( \theta_w \) is the weak angle. \( \kappa^2_{\gamma} \) is the anomalous coupling with the photon, \( \kappa^2_{\gamma} \) is the for the \( Z \) boson, and \( \kappa^2_k \) is the coupling with the gluon. \( \Lambda \) is the scale for new interactions.

For the decays \( Q' \rightarrow Vq \), where \( V = \gamma, Z, g \), we use the effective Lagrangian to calculate the anomalous decay widths,

\[
\Gamma(Q' \rightarrow gq) = \frac{2}{3} \left( \frac{\kappa^2_{\gamma}}{\Lambda} \right)^2 \alpha m_{Q_r}^3 \lambda_0,
\]

\[
\Gamma(Q' \rightarrow \gamma q) = \frac{1}{2} \left( \frac{\kappa^2_{\gamma}}{\Lambda} \right)^2 \alpha \sqrt{m_{Q_r}^3 \lambda_0},
\]

\[
\Gamma(Q' \rightarrow Zq) = \frac{1}{16} \left( \frac{\kappa^2_{\gamma}}{\Lambda} \right)^2 \frac{\alpha m_{Q_r}^3 \lambda_0}{\sin^2 \theta_w \cos \theta_w} \lambda_Z \sqrt{\lambda_r},
\]

with

\[ \lambda_0 = 1 - 3m_q^2/m_{Q_r}^2 + 3m_q^4/m_{Q_r}^4 - m_q^6/m_{Q_r}^6, \]

\[ \lambda_Z = 2 - 2m_q^2/m_{Q_r}^2 - m_q^4/m_{Q_r}^4 + 2m_q^4/m_{Q_r}^4 - 6m_q^6/m_{Q_r}^6 - m_q^2/m_{Q_r}^2. \]

The anomalous decay widths in different channels are proportional to \( \Lambda^{-2} \), and they begin to contribute more when \( \kappa/\Lambda > 0.1 \text{ TeV}^{-1} \).

The total decay width of the \( t' \) quark is shown in Fig. 1. In Table I, we give the numerical values of the total decay width and branching ratios for the parametrizations PI–PIII. As it can be seen from these tables, for the mass range of \( m_t' \) relevant to LHC experiments, the fractions of

![FIG. 1 (color online). Decay width of the \( t' \) quark depending on its mass for different \( V_{Qq} \) parametrizations and \( \kappa/\Lambda \) values.](http://example.com/figure1.png)
the anomalous decay modes are 99.9% (95%–96%), 98% (37%–41%), and 58%–62% (99%) at $\kappa/\Lambda = 1(0.1)$ TeV$^{-1}$ for the parametrizations PI, PII, and PIII, respectively. However, SM decay modes of $t'$ become dominant at PII and PIII parametrizations when $\kappa/\Lambda = 0.1$ TeV$^{-1}$.

If the CKM unitarity is strictly applied and the $Q'$ mixing with light quarks is strongly constrained, which corresponds to $|V_{q'i}| \approx 0$ for the light quarks $q_i$, there still remains room for the SM decays $t' \to W^+ b$ and the possible anomalous decays $t' \to Vq_i$. In this case, $t'$ can have significant FCNC couplings. When the anomalous interactions greatly dominate over the SM decays, still allowing only the nonvanishing element $|V_{q'i}| \approx 1$ (but assuming $t'$ and $b'$ are mass degenerate), the decay widths and branching ratios of the fourth-family quarks with the anomalous interactions are shown in Table II. Taking the anomalous coupling $\kappa/\Lambda = 0.1$ TeV$^{-1}$, we calculate the $t'$ anomalous decay widths $\Gamma = 8.79 \times 10^{-2}$ GeV, $\Gamma = 3.86 \times 10^{-1}$ GeV, and $\Gamma = 1.02$ GeV for $m_{t'} = 350$, 550, and 750 GeV, respectively.

### III. ANOMALOUS RESONANT PRODUCTION OF $t'$ QUARKS

In order to study the resonant production of fourth-family quarks, we have implemented the anomalous interaction vertices with the new particles $t'$ into the COMPHEP package [26]. In all numerical calculations, the parton distribution functions (PDF) $f_g(x, Q^2)$ and $f_q(y, Q^2)$ are set to the CTEQ6M parametrization [27] and the factorization scale $Q^2 = m_{t'}^2$ is used. The total cross section for the process $pp \to W^+ bX$ is given by

$$\sigma = \int_{\tau_{\text{min}}}^{1} d\tau \int_{\tau}^{1} \frac{dx}{x} f_g(x, Q^2)f_q(\frac{\tau}{x}, Q^2)\hat{\sigma}(\tau s),$$

where $\hat{\sigma} = \sigma$ and $\tau_{\text{min}} = (m_{t'} + m_{q_i})^2/s$; $\hat{\sigma}$ is the partonic cross section for a given process. We consider the production $qg \to t'$ and the decay $t \to W^+ b_j$. In the generic

![Diagrams for the $gq_i \to W^+ q_j$ subprocess including $Q'qg$ (where $Q' = t'$) anomalous vertices; $q_i$ can be any of the quarks inside the proton, while $q_j$ can be any of the quark flavors depending on the charged current interaction. For the $W^+ q_j$ final states we may change the direction of the current lines and replace the incoming antiquarks.](095009-4)

IV. SIGNAL AND BACKGROUND

The resonant production mechanisms of the fourth-family $t'$ quarks depend on the anomalous coupling $\kappa/\Lambda$, while their anomalous decays and charged current decays depend on both these couplings and the $4 \times 4$ CKM matrix elements. The signal process $pp \rightarrow W^+bX$ includes $t'$ exchange in the $s$ channel. The $s$-channel contribution to

the signal process would manifest itself as resonance around the $t'$ mass value in the $W$-boson + jet reconstructed invariant mass. When we consider the leptonic $W$ decays, the $t'$ signal search will be $\ell^+ + b_{\text{jet}} + \not{E}_T$, where $\ell = e, \mu$. For the hadronic $W$ decays one would seek the events with one $b$ jet alongside two more jets, requiring these to have an invariant mass peak around the $W$ mass. If we consider the dominance of the SM decay mode over the anomalous decay, the $t'$ resonant production signal will be

$$pp \rightarrow t'(\tilde{t})X, \quad t'(\tilde{t}) \rightarrow W^+(\tilde{b})_b \quad \text{or} \quad W^+(\tilde{b})_j,$$

which includes further leptonic or hadronic decays of the

FIG. 7 (color online). Partonic-level $p_T$ distributions of $b$ quarks from the signal + background process $pp \to W^+ bX$ at $\sqrt{s} = 14$ TeV. Here, the scale is taken as $\Lambda = 1$ TeV. The peaks occur around respective half mass values of the $t'$ quark masses.
W⁺ boson. In the second and third lines, the elements of the 4 × 4 CKM matrix, $V_{tb}$ and $V_{tq}$, enter the decay process for the $t'$ signal. The cross section for the SM process $pp \rightarrow W^+ bX$ ($pp \rightarrow W^- \bar{b}X$) is $10.14 \text{ pb}$ ($9.78 \text{ pb}$) without any cuts at 14 TeV, and $5.73 \text{ pb}$ ($5.49 \text{ pb}$) at 10 TeV. For the cross section estimates, we assume the efficiency for $b$ tagging to be $e_b = 50\%$, and rejection factors $r_j = 100$ for light jets, and $r_c = 10$ for $c(\bar{c})$ quark jets since they are assumed to be mistagged as $b$ jets. The $p_T$ distributions for both signal and background are given in Fig. 7, including the interference terms. Moreover, different background processes contributing to the same final state are presented in Table VI with various $p_T$ cuts. At the center-of-mass energy $\sqrt{s} = 10$ TeV, the background cross sections are calculated as $0.375 \text{ pb}$ ($0.354 \text{ pb}$) for $W^+ b$ ($W^- b$), and $2.69 \times 10^3 \text{ pb}$ ($1.88 \times 10^3 \text{ pb}$) for $W^+ j$ ($W^- j$) with $p_T > 50$ GeV. The invariant mass distributions of the $b\ell\nu$ system at partonic level for

**TABLE VI.** Cross sections for the backgrounds ($W^\pm b$ and $W^\pm j$) with $p_T$ cuts at the center-of-mass energy $\sqrt{s} = 14$ TeV.
FIG. 9 (color online). Transverse momentum of the $b$ jet versus $W^+b$ invariant mass at $\sqrt{s} = 14$ TeV. On the upper panel only the background distribution with $W^+b$ (black) and $W^+j(b)$ (cyan) events is shown, while on the lower panel both the background and signal distributions with masses of 350 (red), 550 (green), and 750 GeV (blue) are shown. Here, the anomalous coupling is taken to be $\kappa/\Lambda = 1$ TeV$^{-1}$ and the mixing with the fourth-family quark $t'$ is parametrized as the PII.

FIG. 10 (color online). The $p_T$ distributions of jets, electrons, and muons from the signal ($t' \rightarrow W^+b$, left panel) and background ($W^+b$, right panel) after detector simulation. The jets are ordered according to the magnitude of their transverse momenta; here we apply the cuts $p_T^{j1} > 50$ GeV, $p_T^{j2} > 20$ GeV, $p_T^{j3} > 20$ GeV, and $E_T > 20$ GeV.

FIG. 11 (color online). The $\eta$ distributions of jets, electrons, and muons from the simulated signal ($t' \rightarrow W^+b$, left panel) and background ($W^+b$, right panel). The jets are ordered according to the magnitude of their $p_T$. Typical LHC detectors have the acceptance for $|\eta| < 2.5$ when utilization of the inner tracker is imposed.
different parametrizations are given in Fig. 8. Here, the $W^+ b$ and $W^+ j$ backgrounds are included with the assumed efficiencies and acceptance factors. In Fig. 9, we show a density plot of the transverse momentum of the $b$ quark and the invariant mass distribution of the $W^+ b$ system with the $t'$ mass constraint.

V. ANALYSIS

At the generator level, we have required a $b$ jet with transverse momentum of at least $p_T^b > 50$ GeV for the $W^+ b$ events. The events generated for each subprocess are mixed using the “mix” script which can be found in the COMPHEP package [26], and passed to the PYTHIA [28] for further decays and hadronization using the CPYTH package [29]. After $W$-boson decay and hadronization, the detector effects, such as acceptance and resolution, are simulated with the PGS4 program [30] using generic LHC detector [31] parameters. This fast simulation includes the most important detector effects, such as $p_T$ smearing, $E_{\text{em}}$

![Graph 2](image2.png)

Fig. 13 (color online). Mass reconstruction of the $t'$ signal ($b\ell\nu$) (solid line) with $\kappa/\Lambda = 0.4$ TeV$^{-1}$ for $m_{t'} = 400$ GeV (upper-left panel), $m_{t'} = 500$ GeV (upper-right panel), and $m_{t'} = 600$ GeV (lower panel), and the corresponding background (dashed line) at $\sqrt{s} = 10$ TeV.
and $E_{\text{had}}$ smearing, energy deposited in towers (granularity), and tag efficiencies of the remaining detector effects such as misidentifications. More realistic simulations require the resources of the LHC collaborations and are beyond the scope of this work. The EXROOTANALYSIS package [32] is used for PGS4 data and the output is analyzed and histogrammed with the ROOT [33] macros. Since the cross section for $t' \rightarrow W^+ b$ is about 5 times larger than the $t' \rightarrow W^-\bar{b}$ cross section, the analysis for the former process has been considered for the remainder of this study.

Typical kinematical distributions are shown in Figs. 10 and 11. In the event analysis, the signal ($t' \rightarrow W^+ b$, with $\kappa/\Lambda = 0.1 \text{ TeV}^{-1}$ and $m_{t'} = 400, 500, 600 \text{ GeV}$) and background ($W^+ b$) are taken into account assuming the PIII parametrization. The $W$-boson invariant mass can be reconstructed from its leptonic or hadronic decays. For the leptonic reconstruction case, the criteria applied to the electrons or muons are $p_T > 20 \text{ GeV}$ and $|\eta| < 2.5$, whereas for missing transverse energy, the requirement is $E_T > 20 \text{ GeV}$. For the hadronic reconstruction case, we require at least two jets with $p_T > 20 \text{ GeV}$ and $|\eta| < 2.5$. For the reconstruction of the $t'$-quark invariant mass, the $b$-tagged jets are required to have $p_T > 50 \text{ GeV}$ and $|\eta| < 2$ for both cases.

The final results are presented only for the case where the $W$ boson is reconstructed from its leptonic decays. The four-momentum vector of the neutrino is calculated from lepton and missing transverse energy assuming a $W$-boson rest mass constraint. The plots for the reconstructed $t'$ invariant mass after detector simulation are given in Fig. 12 at $\sqrt{s} = 14 \text{ TeV}$ and in Fig. 13 at $\sqrt{s} = 10 \text{ TeV}$. We include the possible backgrounds contributing to the same final state, and count the signal ($S$) and background ($B$) events in the corresponding mass intervals to calculate the statistical significance (SS) defined as [34]

$$SS = \sqrt{2 \left( \frac{S+B}{B} \ln \left( \frac{S+B}{B} \right) - \frac{S}{B} \right)}$$  \hspace{1cm} (14)  

In Table VII, the significance calculations are presented for different mass and anomalous coupling values at $\sqrt{s} = 10 \text{ TeV}$. Here, we use the mass bin width $\Delta m = \text{max}(2\Gamma, \delta m)$ to count signal and background events with the mass resolution $\delta m$. The significance increases with $\kappa/\Lambda$, assuming a maximal mixing between the fourth- and the third-family quarks. The results of this study show that, with early LHC data, one can discover extra up-type quarks if there is a large anomalous coupling with other up-type quarks.

## VI. CONCLUSION

Anomalous interactions could become significant at tree-level processes due to possible large masses of the fourth-family quarks. The fourth-family $t'$ quarks can be produced with large numbers if they have anomalous couplings that dominate over the SM chiral interactions. Following the results from the signal significance for $t'$ anomalous production, the sensitivity to the anomalous coupling $\kappa/\Lambda$ can be reached down to $0.1 \text{ TeV}^{-1}$ in the $b$-jet + lepton + $E_T$ channel at $\sqrt{s} = 10 \text{ TeV}$, assuming a maximal parametrization for the extended CKM elements. The LHC experiments can observe the fourth-family quarks mostly in pairs, and single in the $s$-channel if they have large anomalous couplings to the known quarks. If detected at the LHC experiments, the fourth-family quarks will change our perspective on the flavor and the mass.
