Recent results of searches for exotic phenomena (new phenomena other than Supersymmetry) with the ATLAS experiment at the Large Hadron Collider conducted with proton–proton collision data at $\sqrt{s} = 8$ TeV taken 2012 were presented. If not explicitly stated otherwise a dataset with 20.3 fb$^{-1}$ is used by the discussed analyses.

Keywords: ATLAS; Exotic; Searches.

PACS numbers:

1. Introduction

Recent results of searches for exotic phenomena (new phenomena other than Supersymmetry) with the ATLAS experiment at the Large Hadron Collider (LHC) conducted with proton–proton collision data at a centre-of-mass energy of $\sqrt{s} = 8$ TeV taken 2012 were presented. If not explicitly stated otherwise a dataset with 20.3 fb$^{-1}$ is used by the discussed analyses.

2. Multi-jet Search

A search for evidence of physics beyond the Standard Model (SM) in final states with multiple high-transverse-momentum jets is performed. To identify high-$p_T$, high-multiplicity final states resulting from high-mass objects, a suitable variable is the scalar sum of the $p_T$ of the jets in the event, $H_T$. No significant excess of events beyond SM expectations is observed (see: Figure 1). A wide variety of models for black hole and string ball production and decay are considered, and the upper limit on the cross-section times acceptance is as low as 0.16 fb at the 95% confidence level (CL) (see: Figure 2).

3. Search for Black Holes and String Balls with Leptons and Jets

A search for an excess of events with multiple high transverse momentum objects including charged leptons and jets is presented. No excess of events beyond SM expectations is observed (see: Figure 3). The analysis considers events at high $\sum p_T$, defined as the scalar sum of the $p_T$ of the selected reconstructed objects (hadronic jets and leptons), containing at least three high-$p_T$ objects (leptons or jets), at least one of which must be a lepton. Using extra-dimensional models for black hole and string ball production and decay, exclusion contours are determined as a function of the mass threshold for production and the fundamental gravity scale for two, four and six extra dimensions (see: Figure 4). For six extra dimensions, mass thresholds of 4.8–6.2 TeV are excluded at 95% CL, depending on the fundamental gravity scale and model assumptions.

4. Dark Matter

Results of a search for new phenomena in events with large missing transverse momentum and a Higgs boson decaying to two photons are reported. The observed data are well described by the expected SM backgrounds. Exclusion limits are presented for models of physics beyond the SM featuring dark matter candidates, as for example illustrated in Figure 5. Prior to these results, no bounds have been placed by collider experiments on the Higgs boson+dark matter models.
Fig. 2. Upper limits on the visible cross-section (cross-section ($\sigma$) times acceptance ($A$) times efficiency ($\epsilon$)) at the 95% CL versus inclusive $H_T$ for different inclusive jet multiplicities, (a) $N_{\text{jet}} \geq 3$ and (b) $N_{\text{jet}} \geq 8$. The solid (dashed) lines correspond to the observed (expected) upper limits. The green (dark) and yellow (light) bands represent one and two standard deviations from the expected limits.

Fig. 3. The $\sum p_T$ distributions in the (a) electron and (b) muon channels. Two representative signal distributions for rotating black holes with $n = 6$ are overlaid to illustrate the signal properties. The lower panels show the ratio of the data to the expected background, with the statistical uncertainty on data (points), and separately, the fractional total uncertainty on the background (shaded band).
Fig. 4. The exclusion limits in the (a) $M_{th}-M_D$ and (b) $M_{th}-M_S$ plane, with electron and muon channels combined, for (a) non-rotating black hole models two, four and six extra dimensions, simulated with BlackMax and (b) rotating and non-rotating string ball models with six extra dimensions. The solid (dashed) lines show the observed (expected) 95% CL limits, with the band illustrating the expected $\pm 1\sigma$ variation of the expected limits for the (a) $n=6$ (b) non-rotating case. The $\pm 1\sigma$ variation is comparable for the (a) $n=2$ and $n=4$ models (b) rotating case. Masses below the corresponding lines are excluded. The lighter grey lines indicate constant (a) $k = M_{th}/M_D$ (b) $k = M_{th}/M_S$.

Fig. 5. (a) Distribution of the diphoton invariant mass $m_{\gamma\gamma}$. An unbinned maximum-likelihood fit to the spectrum is used to estimate the number of events from the continuum background and from $H \rightarrow \gamma\gamma$ decays the individual components are shown as well as their sum. (b) Limits on coupling parameters for simplified models with a heavy mediator with mass of 1 TeV. All constraint contours exclude larger couplings or mixing angles. Regions excluded due to perturbativity arguments are indicated red, green and pink contours denote results from collider searches for invisible $H$ decays and monojet searches, and the LUX Collaboration respectively.
5. Excited Quarks and Quark Compositeness Searches with Dijet Angular Distributions

A search for new phenomena in LHC proton–proton collisions at $\sqrt{s} = 8$ TeV was performed with the ATLAS detector using an integrated luminosity of 17.3 fb$^{-1}$. The angular distributions are studied in events with at least two jets the highest dijet mass observed is 5.5 TeV. All angular distributions are consistent with the predictions of the SM (see: Figure 6). In a benchmark model of quark contact interactions, a compositeness scale below 8.1 TeV in a destructive interference scenario and 12.0 TeV in a constructive interference scenario is excluded at 95% CL.

6. One Measurement many Interpretations: Search for Top Quark Pair Resonances

A search for new particles that decay into top quark pairs, $t\bar{t}$, is reported. The lepton-plus-jets final state is used, where the top pair decays to $W^+bW^-\bar{b}$, with one $W$ boson decaying leptonically and the other hadronically. The invariant mass spectrum of top quark pairs is examined for local excesses or deficits that are inconsistent with the SM predictions (see: Figure 7). Events are reconstructed assuming...
the final state originated from a $t\bar{t}$ decay. To calculate $m_{t\bar{t}}^{\text{reco}}$, the neutrino four-momentum must be determined. The neutrino transverse momentum is taken to be the $E_{T}^{\text{miss}}$ vector. The longitudinal component of the neutrino momentum, $p_{z}$, is calculated by constraining the lepton plus missing momentum system to have the $W$ boson mass and solving the resulting quadratic equation in the neutrino’s longitudinal momentum $p_{z}$. If no real solution exists, the $E_{T}^{\text{miss}}$ vector is varied by the minimal amount required to produce exactly one real solution. If two real solutions are found, the one with the smallest $|p_{z}|$ is used for the boosted-topology reconstruction, while the choice is made by a $\chi^2$ algorithm. For the boosted topology, $m_{t\bar{t}}^{\text{reco}}$ is computed from the four-momenta of the neutrino, lepton, the selected small-radius jet and the large-radius jet. In this case the assignment of jets to the semileptonically decaying top quark and hadronically decaying top quark is unambiguous. No evidence for a top quark pair resonance is found, and 95% CL limits on the production rate are determined for massive states in benchmark models. The upper limits on the cross-section times branching ratio of a narrow a $Z'$ boson decaying to top pairs range from 4.2 pb to 0.03 pb for resonance masses from 0.4 TeV to 3.0 TeV. A narrow leptophobic topcolour $a_{Z}'$ boson with mass below 1.8 TeV is excluded. Upper limits are set on the cross-section times branching ratio for a broad colour-octet resonance with $\Gamma/m = 15\%$ decaying to $t\bar{t}$. These range from 4.8 pb to 0.09 pb for masses from 0.4 TeV to 3.0 TeV. A Kaluza–Klein excitation of the gluon in a Randall–Sundrum model is excluded for masses below 2.2 TeV (see: Figure 8).

Searches for Exotic Phenomena with the ATLAS Detector

(a) $Z'$, resolved and boosted combination. (b) $g_{KK}$, resolved and boosted combination.

(c) $G_{KK}$, resolved and boosted combination. (d) Scalar resonance, resolved and boosted combination.

Fig. 8. Observed and expected upper limits on the production cross-section times branching ratio to $t\bar{t}$ final states as a function of the mass of (a) Topcolour-assisted-technicolour $Z'_{TC2}$, (b) Bulk RS Kaluza–Klein gluon, (c) Bulk RS Kaluza–Klein graviton, (d) scalar resonance. The expected limits are derived from nominal (pre-fit) background estimates. The theoretical predictions for the production cross-section times branching ratio at the corresponding masses are also shown.

7. Vector Like Quarks

A search for pair production of vector-like quarks, both up-type ($T$) and down-type ($B$), as well as for four-top-quark production (see: Figure 9), is presented. Data are analysed in the lepton-plus-jets final state, characterised by an isolated electron or muon with high transverse momentum, large missing transverse momentum and multiple jets. Dedicated analyses are performed targeting three cases: a $T$ quark with significant branching ratio to a $W$ boson and a $b$-quark ($TT \rightarrow WbX$), and both a $T$ quark and a $B$ quark with significant branching ratio to a Higgs boson and a third-generation quark ($TT \rightarrow Ht+X$ and $BB \rightarrow HbX$ respectively, see for example: Figure 10). No significant excess of events above the SM expectation is observed, and 95% CL lower limits are derived on the masses of the vector-like $T$ and $B$ quarks under several branching ratio hypotheses assuming...
contributions from $T \rightarrow Wb, Zt, Ht$ and $B \rightarrow Wt, Zb, Hb$ decays. The 95% CL observed lower limits on the $T$ quark mass range between 715 GeV and 950 GeV for all possible values of the branching ratios into the three decay modes, and are the most stringent constraints to date (see: Figure 11).

Fig. 9. Representative leading-order Feynman diagrams for $T \bar{T}$ production probed by (a) the $T \bar{T} \rightarrow Wb+X$ search and (b) the $T \bar{T} \rightarrow Ht+X$ search, and (c) for $B \bar{B}$ production probed by the $B \bar{B} \rightarrow Hb+X$ search.

8. Heavy Long-Lived Multi-Charged Particles

A search for heavy long-lived multi-charged particles was presented. Particles producing anomalously high ionisation, consistent with long-lived massive particles with electric charges from $|q| = 2e$ to $|q| = 6e$ are searched for. No signal candidate events are observed, and 95% CL cross-section upper limits are interpreted as lower mass limits for a Drell–Yan production model (see: Figure 12). The mass limits range between 660 and 785 GeV.

9. Outlook

Searches for exotic signatures with the ATLAS detector were presented. A non-exhaustive overview of results of the ATLAS Exotics group is provided in Figure 9. In the LHC Run II data and its analyses the cross-section improvements due to the increased centre-of-mass energy of the LHC of $\sqrt{s} = 13$ TeV compared to $\sqrt{s} = 8$ TeV in Run I will significantly expand our sensitivity for new physics.
Fig. 10. \( T\bar{T} \to Ht+X \) search: comparison between data and prediction for the distribution of the scalar sum (\( H_{T} \)) of the transverse momenta of the lepton, the selected jets and the missing transverse momentum in each of the analysed channels after final selection: (a) (5 j, 2 b), (b) (\( \geq 6 \) j, 3 b, low \( M_{bb}^{\min} \)), (c) (5 j, 2 b), and (d) (\( \geq 6 \) j, 3 b, low \( M_{bb}^{\min} \)). The background prediction is shown after the fit to data under the background-only hypothesis. The small contributions from W/Z+jets, single top, diboson and multi-jet backgrounds are combined into a single background source referred to as “Non-\( \bar{t}t \)”. The last bin in all figures contains the overflow. The bottom panel displays the ratio of data to the total background prediction. The hashed area represents the total uncertainty on the background.
Fig. 11. Summary of the most restrictive observed limit (95% CL) on the mass of the (a) $T$ quark in the plane of $\text{BR}(T \rightarrow Ht)$ versus $\text{BR}(T \rightarrow Wb)$ and (b) $B$ quark in the plane of $\text{BR}(B \rightarrow Hb)$ versus $\text{BR}(B \rightarrow Wt)$ from all ATLAS searches for $TT$ or $BB$ production, respectively. Contour lines are provided to guide the eye.\[10]

Fig. 12. (a) Normalised distributions of the $dE/dx$ significance in the Monitored Drift Tubes (MDT), $S(\text{MDT } dE/dx)$ versus the Transition Radiation Tracker of the Inner Detector (TRT), $S(\text{TRT } dE/dx)$ after the $z \geq 3$ tight selection. The distributions of the data and the simulated signal samples (here for a mass of 600 GeV) are shown. (b) Observed 95% CL cross-section upper limits and theoretical cross-sections as functions of the multi-charged particle’s mass for values of $z$ between 2 and 6.\[15]
Fig. 13. Reach of ATLAS searches for new phenomena other than Supersymmetry. Blue (green) bands indicate 7 TeV (8 TeV) data results. Only a representative selection of the available results is shown (always up-to-date results are available here: https://twiki.cern.ch/twiki/bin/view/AtlasPublic/ExoticaPublicResults).
