Measurement of the Top Differential Cross Section in the tt-bar to Dilepton Channel in pp Collisions at 13 TeV

Youn Jung Roh for the CMS Collaboration

Abstract

Differential cross sections of top-quark pair production are measured in dilepton decay channel with proton-proton collisions at a center-of-mass energy of 13 TeV. The measurement is performed with a RunII data using CMS detector at the Large Hadron Collider. In this analysis, we measure the differential cross sections with respect to kinematic variables of leptons, bjets, and top-quarks.

Differential cross sections of top-quark pair production are measured in the dilepton decay channel with proton-proton collisions at a center-of-mass energy of 13 TeV. The measurement is performed with a Run II data using CMS detector at the Large Hadron Collider. In this analysis, we measure the differential cross sections with respect to kinematic variables of leptons, b jets, and top-quarks.
1. Introduction

Normalized differential cross sections for top quark pair productions are measured in dilepton (electron or muon) decay channel (shown in Figure 1) with proton-proton collisions at a center-of-mass energy of 13 TeV using CMS experiment [1] in 2015.

Figure 1: Feynman diagram of top-quark pair production in dilepton decay channel. The $l^{\pm}$ symbol indicates a charged lepton.

2. Data samples

The measurement is done with Run II data recorded in 2015 by CMS detector corresponding to an integrated luminosity of 42 pb$^{-1}$. We have used double lepton (electron or muon) triggered data samples and simulation data samples which are generated by POWHEG, MG5_aMC@NLO and Madgraph, showered with either Pythia8 or Herwig++. The simulation includes $t\bar{t}$+jets, Drell-Yan (DY), W+jets, single top quark production and dibosons (WW,ZZ,WZ).

3. Event selection

Figure 2 shows the distribution for the number of jets, jets identified as b’s, and the transverse momentum of leptons and b jets after applying the following event selection and before the kinematic reconstruction of the $t\bar{t}$ system.

- **Electron**: $P_T > 20$ GeV, $|\eta| < 2.4$
- **Muon**: $P_T > 20$ GeV, $|\eta| < 2.4$
- **Jet**: $P_T > 30$ GeV, $|\eta| < 2.4$
- Opposite signed two leading $P_T$ leptons ($ee/\mu\mu/e\mu$) $M_{ll} > 20$ GeV, Z mass veto ($|M_{ll} - 91| < 15$ GeV) for $ee/\mu\mu$
- Missing $E_T > 40$ GeV for $ee/\mu\mu$, 2 jets, 1 b-tagged jet
First measurement of differential cross sections for $t\bar{t}$ production in dilepton final state at 13 TeV collisions

4. Top reconstruction

The top quarks are determined from the four momenta of all final-state objects by means of an algebraic kinematic reconstruction method. The following constraints are imposed: the balance of $P_T$ of the two neutrinos; the W boson and the top quark mass. Effects of detector resolution are accounted by studying of object’s detector response. The neutrino momenta are yielded with smallest invariant mass of the $t\bar{t}$ system. In case of ambiguity, the solution for the momenta of the neutrinos is chosen as the one which yields the lowest mass of the $t\bar{t}$ system. For each solution, a weight is calculated based on the expected true invariant mass spectrum of the lepton and b jet.
Over 100 reconstruction attempts, the top quarks are calculated as a weighted average.

5. Normalized differential cross section

Normalized differential $t\bar{t}$ cross section is measured as a function of jet multiplicity and of kinematic variables of top quark and $t\bar{t}$ system, as follows:

$$\frac{1}{\sigma} \frac{d\sigma_i}{dX} = \frac{1}{\sigma} \frac{x_i}{\Delta_i X}$$ (1)

where $x_i$ is the number of signal events measured in data after background subtraction and corrected for detector efficiencies, acceptances, and migrations. The correction is done using a regularized unfolding method $(\Sigma_j A_{ij} - 1)[N_{data,j} - N_{bk,j}]$ where $A$ : response matrix of kinematic variables, $N_{data/bk}$: number of data/estimated background). $\Delta_i X$ is the bin width. $\sigma$ is total cross section. $X$ represents a variable such as the jet multiplicity, top $P_T$, top rapidity, $t\bar{t} P_T$ [2].

6. Result

The normalized differential cross section as a function of the jet multiplicity is determined at the particle level, where the physics objects are defined as follows: $P_T > 20$ GeV, $|\eta| < 2.4$. The top quark and $t\bar{t}$ system observables are defined with respect to the top quarks or antiquarks before the decay (parton level) and after QCD radiation, and extrapolated to the full phase space (See Figure 3).

7. Conclusion

Normalized differential cross sections for top quark pair production are measured in dilepton decay channel with respect to the jet multiplicity, top $P_T$, top rapidity, $t\bar{t} P_T$. The measurements are compared to predictions from POWHEG + PYTHIA8, MG5 aMC@NLO + PYTHIA8, MADGRAPH + PYTHIA8, and POWHEG + HERWIG++. The measurements are in agreement with standard model predictions.
