Abstract

The spectrum of the Quantum pendulum with the anisotropy parameter being a root of unity is expressed in terms of an algebraic Bethe ansatz. Within this context a short survey about the connections between the involved algebras of the sine-Gordon and Volterra model is given.

1 Introduction

The content of this paper is mainly based on the work of Faddeev and Volkov in [FV], [F], [V]. In [V] the so-called quantum Volterra model was established. This involved in particular the derivation of an quantum Volterra-L-Operator, which satisfies the usual Quantum-Yang-Baxter equation with the trigonometric R-Matrix of the sine-Gordon model. A fundamental L-Operator acting as an R-Matrix on quantum space was constructed. In [FV] it was shown how this integrability could be written as a Quantum Zero Curvature condition on the lattice and quantum evolution operators were constructed. Among others a connection between the quantum Volterra model and the quantum sine-Gordon model was found in [FV] via the construction of the sine-Gordon L-operator from the Volterra-L-operator by expressing it in terms of the sine-Gordon Π and Φ fields. In [F] the algebraic Bethe ansatz for this L-operator was given.

The fundamental L-operator of the Volterra model is, as found in [V], dependent on a subalgebra of the original Volterra algebra, which we would like to call the C-Algebra. This subalgebra can be depicted as being an algebra on the faces of the lattice rather than being an algebra on the edges of the lattice, as in the case of the original Volterra algebra. Since the Hamiltonian of the Volterra model is

*Supported by the Deutsche Forschungsgemeinschaft, Sonderforschungsbereich 288

derived from this fundamental L-operator it depends also only on this subalgebra. In [BKP] it was shown at the example of the monodromy of four lattice sites (the Quantum pendulum) that the trace of a multiple of the Volterra-L-Operator might also be expressed in terms of this algebra. Furthermore it was shown that the zero curvature equation of the Volterra model can be written in this subalgebra, which gives the quantum discrete sine-Gordon equation.

In this paper it will be shown that the C-Algebra is not only a subalgebra of the Volterra algebra, but also of the Π and Φ sine-Gordon algebra. Since it is only a subalgebra, the algebraic Bethe ansatz constructed in [F] can not fully be applied. Consequently only parts of the spectrum of the Quantum pendula can be recovered in terms of the algebraic Bethe ansatz of [F].

2 Connections between the models

Let us consider the L-operator of the quantum Volterra model [V].

$$V_n(\lambda) = \begin{pmatrix} u_n & -e^\lambda v_n^{-1} \\ e^\lambda v_n & u_n^{-1} \end{pmatrix} \quad (2.1)$$

with u, v obeying the ultralocal commutation relations:

$$u_n v_n = e^{-\alpha} v_n u_n \quad [u_j, u_k] = [v_j, v_k] = [u_j, v_k] = 0, \text{ if } j \neq k.$$

It satisfies the fundamental commutation relations (FCR):

$$R(\lambda - \mu) V_n(\lambda, a) \otimes V_n(\mu, a) = V_n(\mu, a) \otimes V_n(\lambda, a) R(\lambda - \mu) \quad (2.2)$$

where $R(\lambda)$ is the R-matrix of the Sine-Gordon model (see e.g. [IK],[STF]):

$$R(\lambda) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & b(\lambda) & c(\lambda) & 0 \\ 0 & c(\lambda) & b(\lambda) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad \begin{aligned} b(\lambda) &= \frac{e^{-\alpha} - e^\alpha}{e^{\mu-\lambda-\alpha} - e^{\lambda-\mu+\alpha}}; \\ c(\lambda) &= \frac{e^{\mu-\lambda} - e^{\lambda-\mu}}{e^{\mu-\lambda-\alpha} - e^{\lambda-\mu+\alpha}} \end{aligned}$$

The fundamental L-operator $\mathbf{L}_{\alpha,\beta}(\lambda) = \mathbf{P}_{\alpha,\beta} l(\lambda, u_\alpha^{-1} u_\beta^{-1} v_\alpha^{-1} v_\beta)$ satisfies the equation [V]:

$$\mathbf{L}_{\alpha,\beta}(\lambda) V_\alpha(\lambda + \mu) V_\beta(\mu) = V_\beta(\mu) V_\alpha(\lambda + \mu) \mathbf{L}_{\alpha,\beta}(\lambda) \quad (2.3)$$

where $\mathbf{L}_{\alpha,\beta}(0) = \mathbf{P}_{\alpha,\beta}$, is the permutation operator on the two quantum spaces α and β and l a function given in [V]. Faddeev and Volkov constructed in [FV] shift operators $U_\pm$ which determine the evolution in the light cone directions:

$$\tilde{V}_\alpha(\lambda - \omega) = U_+^{-1} V_\alpha(\lambda - \omega) U_+ \quad \tilde{V}_\beta(\lambda + \omega) = U_- V_\beta(\lambda + \omega) U_-^{-1}.$$

Due to (2.3) and (2.2) the zero curvature condition is satisfied:

$$V_\alpha(\lambda - \omega) V_\beta(\lambda + \omega) = \tilde{V}_\beta(\lambda + \omega) \tilde{V}_\alpha(\lambda - \omega) \quad (2.4)$$

If one multiplies the Volterra-L-operator on two consecutive lattice sites as in [FV]:

$$L_n(\lambda) = V_{2n}(\lambda - \omega) V_{2n-1}(\lambda + \omega) \quad (2.5)$$

and defines on each Cauchy surface

$$\begin{aligned} e^{i\Pi_n} &:= u_{2n} v_{2n-1}^{-1} \\ e^{i\Phi_n} &:= u_{2n}^{-1} u_{2n-1}^{-1} \\ e_n^a &:= u_{2n} v_{2n}^{-1} u_{2n-1} v_{2n-1} \end{aligned}$$

then one obtains the L-operator

$$L_n(\lambda, a) = \begin{pmatrix} e^{-i\Phi_n} - e^{2\lambda} e^{i\Phi_n + a} & -e^{i\Pi_n} h_+(\Phi_n, a) \\ h_-(\Phi_n, a) e^{-i\Pi_n} & e^{i\Phi_n} - e^{2\lambda} e^{-i\Phi_n - a} \end{pmatrix} = \begin{pmatrix} L_n^{11} & L_n^{12} \\ L_n^{21} & L_n^{22} \end{pmatrix} (\lambda, a) \quad (2.6)$$

with

$$\begin{aligned} h_+(\Phi_n, a) &= e^{\lambda+\omega} + e^{\lambda-\omega} e^{2i\Phi_n - \alpha + a} \\ h_-(\Phi_n, a) &= e^{\lambda+\omega} + e^{\lambda-\omega} e^{-2i\Phi_n + \alpha - a}, \quad \text{where } a \in i\mathbb{R}; \lambda \in \mathbb{C} \end{aligned}$$

e^a is a Casimir in the algebra generated by the Π 's and Φ 's. In [F] it was set equal to one: $e^a = 1$, but it will be shown in the following that this constraint has to be given up in order to construct the algebraic Bethe ansatz for the Quantum pendulum. $e^{i\Pi}$ and $e^{i\Phi}$ commute again ultralocally, i.e. $e^{i\Pi_n} e^{i\Phi_n} = e^\alpha e^{i\Phi_n} e^{i\Pi_n}$. Let us define:

$$C_n := u_{2n}^{-1} u_{2n-1}^{-1} v_{2n}^{-1} v_{2n-1} \text{ and } [C_n, C_{n-1}] = 0 \quad (2.7)$$

Note that this operator already appeared in the fundamental L-operator of the Volterra model (2.3). It may be depicted as being an operator on the faces of the lattice, rather than the u and v which can be looked at as operators on its edges. In [BKP] it was shown that the zero curvature condition of the Volterra model can be written in terms of the above algebra:

$$C_u = \frac{k + e^\alpha C_l}{1 + k e^\alpha C_l} C_d \frac{1 + k e^\alpha C_r}{k + e^\alpha C_r} \quad (2.8)$$

The C_i commute nontrivially on adjacent faces only:

$$C_u C_l = e^{2\alpha} C_l C_u,$$

$$C_d C_l = e^{2\alpha} C_l C_d.$$

Proposition 2.1 *Let N be the period of the lattice, then the product $C_{d_1} \dots C_{d_N}$ is preserved by the evolution, i.e*

$$C_{u_1} \dots C_{u_N} = C_{d_1} \dots C_{d_N}$$

Proof:

$$C_{u_1} \dots C_{u_N} = \frac{k + e^\alpha C_1}{1 + k e^\alpha C_1} C_{d_1} \dots C_{d_N} \frac{1 + k e^\alpha C_{N+1}}{k + e^\alpha C_{N+1}} = C_{d_1} \dots C_{d_N}$$

since $C_1(C_{d_1} \dots C_{d_N}) = (C_{d_1} \dots C_{d_N})C_1$, i.e $C_{d_1} \dots C_{d_N}$ is a casimir in the algebra. $\square$

If C_r and C_l shall commute in the same way we have to make the following redefinitions :

$$C_l = Q_l, \quad C_r = Q_r^*, \quad C_d = Q_d^*, \quad C_u = Q_u$$

and for the sake of selfconsistency

$$C_l = Q_l^*, \quad C_r = Q_r, \quad C_d = Q_d, \quad C_u = Q_u^*$$

Both definitions lead to the same equation [BKP]:

$$Q_u Q_d = \frac{k + e^\alpha Q_l}{1 + e^\alpha k Q_l} \frac{k + e^\alpha Q_r}{1 + e^\alpha k Q_r} \quad (2.9)$$

which is called the quantum discrete sine-Gordon equation.

Let us consider now the simplest possible case, namely a lattice with face-periodicity $N = 2$.

The trace of the monodromy in terms of the C-Agebra reads in this case as:

$$M(\lambda) = V_4(\lambda) \cdot V_3(\lambda) \cdot V_2(\lambda) \cdot V_1(\lambda) = \begin{pmatrix} A(\lambda) & B(\lambda) \\ C(\lambda) & D(\lambda) \end{pmatrix} \quad (2.10)$$

$$\begin{aligned}
tr M(\lambda) &= A(\lambda) + D(\lambda) \\
&= e^{-\frac{i\beta}{2} - \frac{i\delta}{2}} + e^{4\lambda} e^{\frac{i\beta}{2} - \frac{i\delta}{2}} \\
&\quad - e^{2\lambda} (e^{-i\beta/2 - i\delta/2} (C_r + C_l + C_d + e^{i\delta} C_d + k e^\alpha C_d C_r + \frac{1}{k} e^\alpha C_l C_d)) \\
&\quad + \text{hermitian conjugate}
\end{aligned} \tag{2.11}$$

There are two casimirs:

$$C_d C_{d'} =: e^{i\beta} \quad \text{and} \quad C_r C_l =: e^{i\delta}$$

Since Q_l and Q_r obey the same commutation relations with their neighbours, one can set $Q_l = Q_r$, which refers to the case of a pendulum [BKP]. Taking the above casimirs into consideration we define:

$$\begin{aligned}
C_l &=: Q_n e^{i\delta/2} &\Rightarrow C_r &=: Q^* e^{i\delta/2} \\
C_d &=: Q_{n-1}^* e^{i\beta/2} &C_{d'} &=: Q_{n-1} e^{i\beta/2},
\end{aligned}$$

where n and $n-1$ refer to the evolution in vertical direction (time).

Proposition 2.2 *The trace of the monodromy of (2.10) can be written as*

$$\begin{aligned}
tr M(\lambda) &= e^{-i\beta} + e^{4\lambda} - e^{2\lambda} H(\beta) \\
H(\beta) &= 2 \cos \frac{\beta}{2} (Q_n + Q_n^* + Q_{n-1} + Q_{n-1}^*) \\
&\quad + k(q^{-1} Q_n^* Q_{n-1}^* + q Q_{n-1} Q_n) \\
&\quad + \frac{1}{k} (q Q_n Q_{n-1}^* + q^{-1} Q_{n-1} Q_n^*),
\end{aligned} \tag{2.12}$$

$\beta \in \mathbb{R}$

$H(\beta)$ is called the hamiltonian of the Quantum pendulum.

Proof:

There is a different possibility to define the Q -Algebra:

$$\begin{aligned}
C_r &=: Q_n e^{i\delta/2}, & C_d &=: Q_{n-1} e^{i\beta/2}, \\
C_l &=: Q_n^* e^{i\delta/2} & C_{d'} &=: Q_{n-1}^* e^{i\beta/2}
\end{aligned}$$

If one substitutes both definitions into (2.11) one sees that the Hamiltonian is only invariant under the time-evolution if one demands that $\alpha = \beta$ and hence gets the above hamiltonian (2.12). $\square$

Proposition 2.3 *Let $H_{Hof} = T + T^* + \frac{1}{k}(S + S^*)$ be the Hamiltonian of the Hofstadter model with $ST = e^{i\gamma}$; $\alpha = i\gamma$ Then with the Substitutions:*

$$Q_n = e^{i\gamma/2} T S \quad \text{and} \quad Q_{n-1} = e^{-i\gamma/2} T S^*$$

one has:

$$k H_{Hof}^2 - (k + \frac{1}{k}) = H(\gamma) \tag{2.13}$$

Proof: Direct computation.

So if $\beta = \gamma$ the Quantum pendulum gives the square of the Hofstadter Hamiltonian. Generally the Quantum pendulum is a model for a Nearest Neighbour interaction on a lattice. [K].

3 Algebraic Bethe ansatz

In the last section we learned about the connection between the sine-Gordon model expressed in terms of the $e^{i\Pi}, e^{i\Phi}$ and e^α -algebra on one hand and via the C -algebra on the other hand. In the first case one can write the spectrum of the trace of the monodromy in terms of algebraic Bethe ansatz equations if $e^\alpha = 1$ [F]. It is possible to generalize this method if one demands that $e^{\frac{\alpha_1 + \alpha_2}{2}} = q^\rho$ is a root of unity with $q^{2n+1} = 1$.

For $e^\alpha = q$ with $q^{2n+1} = 1$ the operators $e^{i\Pi}$ and $e^{i\Phi}$ have finite dimensional representations:

$$e^{i\Pi} = e^{i\phi} \begin{pmatrix} 0 & 0 & . & . & 0 & 1 \\ 1 & 0 & . & . & 0 & 0 \\ 0 & 1 & 0 & . & . & 0 \\ . & . & . & . & . & . \\ . & . & . & . & . & . \\ 0 & . & . & . & 1 & 0 \end{pmatrix} \quad e^{i\Phi} = e^{i\theta} \begin{pmatrix} 1 & 0 & . & . & . & 0 \\ 0 & q & 0 & . & . & . \\ . & 0 & q^2 & 0 & . & . \\ . & . & . & . & . & . \\ . & . & . & . & . & 0 \\ 0 & . & . & . & 0 & q^{n-1} \end{pmatrix}$$

We find in the representation, where $\phi = \pi$ and $\theta = 0$ a vacuum state Ω for the offdiagonal $C(\lambda, a, b)$ of the monodromy in (2.10).

Let $\{e_i = (0, \dots, 1, \dots, 0)^T\}$ be a standard basis on $\mathbb{C}^2$, then one obtains,

$$\Omega = \sum_j f(q^j) e_j \otimes e_{-j-\rho-1} \quad \text{with} \quad f(q^j) = q^{-j^2-\rho j} \mathcal{F}(q^{-1} \underbrace{q^{-2j-\rho}}_w)^{-1}.$$

where $\mathcal{F}$ satisfies the functional equation

$$\frac{\mathcal{F}(q^{-1}w)}{\mathcal{F}(q^1w)} = \frac{\tilde{k} + w}{1 + \tilde{k}w}, \quad \tilde{k} = qk \quad \text{and} \quad w^{2n+1} = 1, \quad k \neq 1.$$

A solution of this equation was proposed in [FZ] and [V] with

$$\mathcal{F} = \sum_{-n}^n l_j w^j \quad \text{and} \quad l_j = \prod_{l=1}^j \frac{q^{l-1} - \tilde{k}q^{-l+1}}{q^{-l} - \tilde{k}q^l}$$

Following the method of the algebraic Bethe ansatz we know now that

$$C(\lambda, \rho)\Omega = 0, \quad A(\lambda, \rho) + D(\lambda, \rho)\Omega = \Lambda(\lambda, \rho)\Omega$$

and

$$(A(\lambda, \rho) + D(\lambda, \rho))B(\lambda_1, \rho)B(\lambda_2, \rho)\dots B(\lambda_k, \rho)\Omega = \Lambda(\lambda, \rho, \lambda_1, \lambda_2, \dots, \lambda_k)\Omega$$

where $\lambda_1, \lambda_2, \dots, \lambda_k$ have to be solutions to the Bethe ansatz equations ($e^{2\lambda_i} =: z_i$):

$$\prod_{\substack{i=0 \\ i \neq j}}^{N-1} \frac{z_j q - z_i q^{-1}}{z_j q^{-1} - z_i q} = q^{2\rho} \frac{q + z_j^2 q^{-1} + z(k + \frac{1}{k})}{q^{-1} + z_j^2 q + z(k + \frac{1}{k})} \quad (3.14)$$

So, in principle, if one would solve the Bethe ansatz equation one could compute the spectrum of $A(\lambda, \rho) + D(\lambda, \rho) =: \text{tr} M(\lambda, \rho)$.

4 On the Spectrum of the Quantum Pendulum

The C-algebra is not only a subalgebra of the u and v -algebra, but may be expressed also via the $e^{i\Phi}, e^{i\Pi}, e^a$ -algebra. In the case of the Quantum pendulum this reads as:

$$\begin{aligned} Q_n &= e^{i\Pi_{2n}-i\Pi_{2n-1}} e^{i\Phi_{2n}-i\Phi_{2n-1}-\alpha} \\ Q_{n-1} &= e^{i\Phi_{2n}-i\Phi_{2n-1}} \\ e^{i\delta_n} &= e^{-(a_{2n}+a_{2n-1})} \\ e^{i\beta_n^{op}} &= e^{2i\Phi_{2n-1}+2i\Phi_{2n}+a_{2n}+a_{2n-1}} \end{aligned} \quad (4.15)$$

We see that the operator $e^{i\beta}$, which is a casimir in the C-algebra is not anymore a casimir in the algebra of $e^{i\Pi}, e^{i\Phi}, e^a$, nevertheless, $e^{i\beta_n^{op}} = e^{2i\Phi_{2n-1}+2i\Phi_{2n}} q^{2\rho}$ is a constant of motion and we have:

$$\begin{aligned} e^{\frac{i\beta_1^{op}}{2}} \Omega &= e^{i\Phi_2+i\Phi_1} q^\rho \sum_{j=0}^{2n} f(q^j) e_j \otimes e_{-j-\rho-1} \\ &= \sum_{j=0}^{2n} q^j q^{-j-1-\rho} q^\rho f(q^j) e_j \otimes e_{-j-\rho-1} \\ &= q^{-1} \Omega. \end{aligned}$$

Furthermore, it can be shown that with

$$\phi_l(\lambda_1, \lambda_2, \dots, \lambda_l, \rho) := B(\lambda_1, \rho) B(\lambda_2, \rho) \dots B(\lambda_l, \rho) \Omega$$

one has

$$e^{\frac{i\beta_{op}}{2}} \phi_l(\lambda_1, \lambda_2, \dots, \lambda_l, \rho) = q^{-(l+1)} \phi_l(\lambda_1, \lambda_2, \dots, \lambda_l, \rho).$$

Consequently if we define $e^{\frac{i\beta_l}{2}} := q^{-(l+1)}$ and $k \neq 1$ we know that $\phi_{l+(2n+1)j}(\lambda_1, \lambda_2, \dots, \lambda_l, \rho)$ is a j 'th eigenstate of

$$H = 2 \cos \frac{\beta_l}{2} (Q_n + Q_n^* + Q_{n-1} + Q_{n-1}^*) + k (q^{-1} Q_n^* Q_{n-1}^* + q Q_{n-1} Q_n) + \frac{1}{k} (q Q_n Q_{n-1}^* + q^{-1} Q_{n-1} Q_n^*)$$

so the algebraic Bethe ansatz of the generalized Sine-Gordon model would - if one could solve the Bethe ansatz equations and if these are sufficient - give the spectrum of the Quantum pendulum for all $e^{\frac{\beta_l}{2}} = q^{-(l+1)}$.

Unfortunately e.g. the square lattice Hofstadter hamiltonian doesn't fall into this class, since there $e^{i\beta} = q$.

In the following figure we see how the eigenvalues of Ω are distributed within the band spectrum of the Quantum pendulum for $k = 2$. On the y-axis are the values of γ and on the x-axis the values of the energy given.

The eigenfunction Ω in a representation with $N = 41$ and $k = 2$.

5 Conclusion

An interesting approach for further investigations would be the application of the functional Bethe ansatz as e.g. in [WZ], where Bethe ansatz equations for the
