April 2018
Search for pair production of Higgs bosons in the four b quark final state with the ATLAS detector

Abstract

This thesis presents a search for Higgs boson pair production, in the $bb\bar{b}b$ final state. This search uses the full 2015 and 2016 datasets collected by the ATLAS Collaboration at center of mass energy $\sqrt{s} = 13$ TeV, corresponding to $3.2 \pm 0.2$ fb$^{-1}$ in 2015 and $32.9 \pm 1.1$ fb$^{-1}$ in 2016 of proton-proton collision data. Improvements with respect to the previous analysis come from the larger dataset, detailed background estimation and additional signal regions. Search sensitivity is particularly enhanced for resonance signals between 2500 GeV and 3000 GeV. The data is found to be compatible with the Standard Model predictions and no signs of new physics have been observed. The results are interpreted in the context of the bulk Randall-Sundrum warped extra dimension model with a Kaluza-Klein graviton $k/M_{pl} = 1.0$ or 2.0 decaying to two Higgs bosons, and the Type 2 two-Higgs doublet model ($2HDM$) where the neutral heavy CP-even scalar decays to two Higgs bosons.
Contents

0 Introduction 1

1 Theory and Motivation 4
  1.1 The Standard Model and the Higgs boson 4
  1.2 Standard Model di-Higgs production 6
  1.3 Beyond the Standard Model di-Higgs production 8
  1.4 Di-Higgs decay and LHC previous search results 13
  1.5 Resolved and Boosted 16

2 LHC and ATLAS 18
  2.1 The Large Hadron Collider 19
  2.2 A Toroidal LHC ApparatuS 22

3 Reconstruction and Objects 27
  3.1 ID Tracks and Vertices 28
  3.2 Jets 29
  3.3 Flavor Tagging 34
  3.4 Leptons 38

4 Data and Simulation 39
  4.1 Data 39
  4.2 MC 41

5 Event Selection 45
  5.1 Data Cleaning 45
  5.2 Trigger 46
  5.3 Object Selection 48
  5.4 Resolved Veto 54
  5.5 2D Higgs Mass Cut 56
  5.6 Number of $b$-tagged track jet requirements 58
## 6 Background Estimation

6.1 Overview

6.2 Definition of the sideband and control regions

6.3 QCD multi-jet

6.4 $t\bar{t}$

6.5 Fitting procedure for QCD and $t\bar{t}$ normalization

6.6 QCD reweighting

6.7 $m_{3J}$ in the sideband region

6.8 $m_{3J}$ in the control region

6.9 $m_{3J}$ rescale and smoothing in the signal region

6.10 Yields

## 7 Systematics

7.1 Overview

7.2 Theoretical uncertainties

7.3 Detector and reconstruction uncertainties

7.4 Background normalization uncertainties

7.5 Background $m_{3J}$ shape uncertainties

7.6 Summary of systematics

## 8 Result

8.1 Boosted signal region

8.2 Resolved signal region

8.3 Statistical analysis

8.4 Boosted and resolved combined limits

## 9 Conclusion
## Appendix E  Reweighting Details

## Appendix F  Validations with low mass and high mass signal region

## Appendix G  Discussion on systematic uncertainties

G.1  Uncertainty on $\bar{t}t$ generator  

G.2  Uncertainty on the shape of $\bar{t}t$ $m_{\ell\ell}$ in the 4/3b signal region  

G.3  Uncertainty on smoothing function in the signal region  

## Appendix H  Effects from variations in the sideband and control region definitions

## References
1.1 Fermions and bosons of the Standard Model and their properties, where all values are measured experimentally.

1.2 Leading order Feynman diagrams contributing to di-Higgs production via gluon-gluon fusion, through the Higgs-fermion Yukawa interactions in Figure 1.2a and the Higgs boson self-coupling in Figure 1.2b. Only Figure 1.2b probes $\lambda_{hhb}$.

1.3 Leading order Feynman diagrams contributing to Higgs pair production via VBF.

1.4 Total cross sections (y-axis) at the NLO in QCD for the six largest di-Higgs production channels at $pp$ colliders for different energy (x-axis). Gluon-gluon fusion, VBF, top-pair, $W^\pm$, $Z$, and single-top associated di-Higgs productions are shown. The thickness of the lines corresponds to the uncertainties added linearly. $H$ refers to the SM Higgs.

1.5 BSM Higgs boson pair production: non-resonant production proceeds through changes in the SM Higgs couplings in Figure 1.5a and Figure 1.5b, resonant production proceeds through Figure 1.5c an intermediate resonance, $X$. $H$ and $b$ both refers to the SM Higgs.

1.6 Total cross sections (y-axis) at the LO and NLO in QCD for di-Higgs production channels, at the LHC $\sqrt{s} = 14$ TeV as a function of the self-interaction coupling $\lambda$ (x-axis). The dashed (solid) lines and light- (dark-) color bands correspond to the LO (NLO) results and to the scale and PDF uncertainties added linearly. The SM values of the cross sections are obtained at $\lambda_{SM} = 1$, indicated by the red vertical line. $H$ refers to the SM Higgs.

1.7 Parton luminosity ratios as a function of resonance mass, $M_X$, for $13/8$ TeV. 1, 2, and 3 TeV $M_X$ ratios are indicated by red lines. For a 2 TeV $X$, the luminosity ratio is almost.

1.8 Reach of ATLAS searches for new phenomena. Only a representative selection of the available results is shown. Blue (green) bands indicate 7 TeV (8 TeV) data results.
1.9 Regions of the $[m_A, \tan \beta]$ plane excluded in the hMSSM model via direct searches for heavy Higgs bosons and fits to the measured rates of observed Higgs boson production and decays. Limits are quoted at 95% CL and are indicated for the data (solid lines) and the expectation for the SM Higgs sector (dashed lines). The light shaded or hashed regions indicate the observed exclusions.

1.10 Summary of di-Higgs final states and their ratios. Top left, $b\bar{b}b\bar{b}$, has the largest branching ratio.

1.11 The observed and expected 95% CL upper limits of $\sigma(gg \rightarrow H) \times BR(H \rightarrow hh)$ at $\sqrt{s} = 8$ TeV as functions of the heavy Higgs boson mass, $m_H$, combining resonant searches in Higgs boson pair to $b\bar{b}\tau^+\tau^-$, $W^+W^-\gamma\gamma$, $b\bar{b}\gamma\gamma$, and $b\bar{b}b\bar{b}$ final states. The expected limits from individual searches are also shown. The green and yellow bands represent $\pm 1\sigma$ and $\pm 2\sigma$ uncertainty ranges of the expected combined limits. The improvement above $m_H = 500$ GeV reflects the sensitivity of the $b\bar{b}b\bar{b}$ analysis. The results beyond 1 TeV are from the $b\bar{b}b\bar{b}$ final state alone.

1.12 Cartoon for $X \rightarrow hh \rightarrow b\bar{b}b\bar{b}$, with resolved event topology (left) and boosted event topology (right).

2.1 A schematic view of the LHC ring. LINAC2, Booster, PS, SPS, and LHC accelerate the protons in order. Four main experiments are located at interaction points along the ring. ATLAS and CMS are general purpose experiments, while ALICE focuses on heavy ion collisions and LHCb is dedicated to $B$ physics.

2.2 The luminosity-weighted distribution of the mean number of interactions per bunch crossing for 2015 and 2016 $pp$ collision data at $\sqrt{s} = 13$ TeV.

2.3 A detailed, computer-generated image of the ATLAS detector and it’s systems.

2.4 Geometry of IBL, PIXEL and SCT detectors in Run 2.

2.5 The overall layout of the ATLAS muon spectrometer.

2.6 Cumulative luminosity vs. time delivered to (green) and recorded by ATLAS (yellow) during stable beams for $pp$ collisions at $\sqrt{s} = 13$ TeV.

3.1 Illustration of particle interactions in ATLAS.

3.2 Two collision events recorded in June 2015 with a high leading jet $p_T$ shown in pseudorapidity-azimuthal angle parameter space. The dots are calorimeter-cell clusters with positive energy. Only the two leading jets are shown, with their area demarcated by a colored circle, with gray regions denoting the corresponding $k_t$ sub-jets of size $R_{sub} = 0.2$. The color of both jets and clusters corresponds to their $p_T$. 
3.3 For the trimming algorithm using calorimeter cell clusters as inputs to the anti-\(k_t\) jet reconstruction algorithm with \(R = 1.0\), a comparison of the jet mass distribution for QCD background jets and \(W\) boson jets low \(p_T\) kinematic regions, as determined by the untrimmed truth jet \(p_T\).

3.4 For the trimming algorithm using calorimeter cell clusters as inputs to the anti-\(k_t\) jet reconstruction algorithm with \(R = 1.0\), a comparison of the jet mass distribution for QCD background jets and \(W\) boson jets high \(p_T\) kinematic regions, as determined by the untrimmed truth jet \(p_T\).

3.5 Uncalibrated (dashed line) and calibrated (solid line) reconstructed jet mass distribution Figure 3.5a, and the jet mass resolution vs jet \(p_T\) Figure 3.5b for calorimeter-based jet mass, \(m_{\text{calo}}\) (red), track-assisted jet mass \(m_{\text{TA}}\) (black) and the invariant mass of four-vector sum of tracks associated to the large-radius calorimeter jet \(m_{\text{track}}\) (blue) for \(W/Z\)-jets.

3.6 Secondary vertex reconstruction rate and MV2c10 output for \(b\)-jets (solid blue), \(c\)-jets (dashed green) and light-jets (dotted red) evaluated with simulated \(t\bar{t}\) events.

3.7 \(b\)-jet efficiency for the fixed cut working point with a \(b\)-jet efficiency of 77% as a function of jet \(p_T\) for the comparison between the MV2c10 \(b\)-tagging algorithm employed for the 2016 analyses (2016 config) and the previous version of the tagger, MV2c20 (2015 config), which has 15% \(c\)-fraction in the training.

3.8 Light-flavor jet and \(c\)-jet rejection as a function of jet \(p_T\) for the previous (2015 config) MV2c20 and the current MV2c10 configuration (2016 config). A fixed cut at 77% \(b\)-jet efficiency operating point is used.

4.1 Trigger efficiencies following the full resolved analysis selection as a function of the resonance signal mass. The efficiencies of the triggers used in 2015 and 2016 are shown. In both graphs, the green line shows the efficiency of the “2b4j” trigger; the blue line represents the “2b3j” trigger; the red line represents the “1b1j” trigger. The 2016 triggers are less efficient due to a bug in the online primary vertex reconstruction.

5.1 2015 ATLAS boosted di-Higgs event candidate’s event display. The data is taken in run 282712, lumiblock 503 and has event number 595661746. ID is in gray, ECAL is in green, HCAL is in red and MS is in blue. Only tracks with \(p_T > 25\) GeV are shown. Jets are gray cones, and ID tracks are colored lines in the ID.

5.2 Different trigger efficiencies as a function of the resonance signal mass with respect to all events without additional selections (left) and with respect to events passing the two large-\(R\) jets and leading (subleading) jet \(p_T > 400(250)\) GeV (right).
5.3 Large-\( R \) jet trigger (HLT_j360_a10_lcw, left and HLT_j420_a10_lcw, right) efficiencies with respect to the large-\( R \) jet \( p_T \), defined as the ratio between events that fired the trigger and all the simulated events, measured in 2015 and 2016 data and \( G_{KK}^b \) with \( c = 1.0 \) MC.

5.4 Percentages of truth Higgs boson contained by a large-\( R \) jet with \( \Delta R_{Higgs,jet} < 1.0 \) as a function of \( G_{KK}^b \) masses. The three cases listed in the legend are orthogonal. Two Higgs bosons almost never match to the same large-\( R \) jet.

5.5 Normalized \( \Delta R \) between the truth Higgs (leading on left, subleading on right) and the truth children \( b \)-quarks for \( G_{KK}^b \) MC. Lines are drawn at \( \Delta R = 0.4 \) (\( R \) of small-\( R \) jets) and \( \Delta R = 1.0 \) (\( R \) of large-\( R \) jets).

5.6 Percentage of \( \Delta R < 0.2 \) matching truth \( b \)'s to track jets (leading Higgs on the left, subleading Higgs on the right) for different \( G_{KK}^b \) masses. The cases listed in the legend are orthogonal to each other. The cases not listed on the legend (including when a truth \( b \) is not contained in the large-\( R \) jet) happen in total at most 1.6% of the total for a given \( G_{KK}^b \) mass.

5.7 Kinematics of 1\( \text{TeV} \) \( G_{KK}^b \) MC before (blue) and after (red) muon-in-jet corrections. The reconstructed Higgs masses (top row, left for leading large-\( R \) jet, right for subleading large-\( R \) jet) are closer to 125 GeV after the correction, which improves the signal efficiency for the signal region selection by \( \sim 10\% \) (bottom row, left for \( m_{jj} \), right for event distribution differences on the leading-subleading large-\( R \) jet mass plane.).

5.8 After large-\( R \) jet requirements, normalized \( \Delta \eta_{JJ} \) distribution in 1.5\( \text{TeV} \) \( G_{KK}^b \) and data, where the data consists of mostly multijet events (> 90%). Higgs candidate refers to the two large-\( R \) jets. The background multijet events are more forward in \( \Delta \eta_{JJ} \) distribution.

5.9 Event display of the same event in 2015 data using resolved 5.9a and boosted 5.9b topologies. The resolved reconstruction gives a \( m_{4j} \) of 873 GeV, and the boosted reconstruction gives \( m_{4j} \) of 852 GeV.

5.10 For RSG \( c = 1.0 \) samples, the number of events as a function of leading Higgs candidate mass and subleading Higgs candidate mass, for 1.2\( \text{TeV} \) (left) signal and 2\( \text{TeV} \) (right) signal samples. The red dotted line in the center correspond to the signal region, passing \( X_{hh} < 1.6 \).

5.11 Signal fraction in different \( b \)-tag categories (left) and detailed fraction in different number of track jet and \( b \)-tag categories (right) as a function of signal resonance mass hypothesis for selection cuts. The efficiencies are relative to the total number of events passing the 2D mass cut.
5.12 Selection efficiency (left) and relative efficiency with respect to the previous cut (right) as a function of RSG c=1.0 signal resonance mass hypothesis for selection cuts. The relative efficiency is defined from the previous cut, where the order of cuts is given by the legend. PassTrig means the event passes the trigger selection; PassDiJetPt means the event passes the leading and sub-leading jet $p_T$-cuts; PassDiJetEta means the event passes the leading and sub-leading jet $\eta$ cuts; PassDetaH means the events passes the $|\Delta \eta| < 1.7$ cut; PassBJetSkim means the event contains at least two $b$-tagged track jets, inclusive of $2b$, $2bs$, $3b$ and $4b$ configurations; PassSignal means the event passes the signal region cut $X_{hb} < 1.6$.

6.1 The $m_{\text{lead}}^{\text{jet}}$ vs $m_{\text{subl}}^{\text{jet}}$ distribution of data in $2bs$ region. The signal region is the area surrounded by the inner (red) dashed contour line, centered on ($m_{\text{lead}}^{\text{jet}}=124$ GeV, $m_{\text{subl}}^{\text{jet}}=115$ GeV). The control region is the area between the signal region and the intermediate (orange) contour line. The sideband region is the area between the control region and the outer (yellow) contour line.

6.2 Detailed signal efficiency in different signal/control/sideband regions in $n$-tagged channels and the inclusive $b$-tagged channel, which includes $2b$, $1b$, and $0b$ as well, (bottom right) as a function of $G_{KK}$ resonance mass for selection cuts. The efficiencies are relative to the total number of events in the preselection.

6.3 Normalized $2bs$, $3b$, and $4b$ $\bar{t}$ MC $m_{\text{jet}}$ (mHH) distribution in the signal region. The uncertainties are statistical.

6.4 Simultaneous fit of $\mu_{\text{qcd}}$ and $\alpha_{\text{t}}$ in $4b$, $3b$ and $2bs$ sideband regions using the leading large-$R$ jet mass.

6.5 Comparison of track jet $p_T$ distributions in different $b$-tag channels. Data are shown in the plots. They contain inclusive SB/CR/SR regions for $ob$ and $1b$, and only the SB region for $2bs$. At the bottom of the plots, all the ratios are taken with respect to the $ob$ tagged distribution.

6.6 The $m_{\text{jet}}$ distributions in the sideband region of the boosted analysis for the data and the predicted background for $4b$, $3b$, and $2bs$ channels. The data-to-background ratio (bottom panels) shows the statistical uncertainties as the gray hatched band.

6.7 The $m_{\text{jet}}$ distributions in the control region of the boosted analysis for the data and the predicted background for $4b$, $3b$, and $2bs$ channels. The data-to-background ratio (bottom panels) shows the statistical uncertainties as the gray hatched band.
6.8 Normalized scaled $m_{4j}$ distributions for the 4$b$ (left), 3$b$ (middle), and 2$bs$ (right) signal regions. For comparison, the unscaled $m_{4j}$ distributions are shown on the same plot.

6.9 Fits for scaled background smoothing are shown for the 4$b$ signal region. The figures show the distributions with the fit central value and the fit variations determined by varying the fit parameters within uncertainties and taking into account parameter correlations.

6.10 Fits for scaled background smoothing are shown for the 3$b$ signal region. The figures show the distributions with the fit central value and the fit variations determined by varying the fit parameters within uncertainties and taking into account parameter correlations.

6.11 Fits for scaled background smoothing are shown for the 2$bs$ signal region. The figures show the distributions with the fit central value and the fit variations determined by varying the fit parameters within uncertainties and taking into account parameter correlations.

6.12 Background predictions for 4$b$ signal region using scaled $m_{4j}$ before and after smoothing. The uncertainty band includes only fit statistical uncertainties.

6.13 Background predictions for 3$b$ signal region using scaled $m_{4j}$ before and after smoothing. The uncertainty band includes only fit statistical uncertainties.

6.14 Background predictions for 2$bs$ signal region using scaled $m_{4j}$ before and after smoothing. The uncertainty band includes only fit statistical uncertainties.

7.1 Impact on $m_{4j}$ of the efficiency scale factor $w_{ij}$ and inefficiency scale factor $w_{ij}^{\text{anti}}$. The MC is 2 TeV $G_{KK}^*$ with $c = 1.0$.

7.2 $m_{4j}$ smoothing fit and ratio in the 4$b$ control region. The uncertainty bands contain the smoothing function parameter variations.

7.3 $m_{4j}$ smoothing fit and ratio in the 3$b$ control region. The uncertainty bands contain the smoothing function parameter variations.

7.4 $m_{4j}$ smoothing fit and ratio in the 2$bs$ control region. The uncertainty bands contain the smoothing function parameter variations.

7.5 Impact of each systematic on MC signal region prediction as a function of the $G_{KK}^*$ mass.

8.1 Unscaled $m_{4j}$ distributions in the 4$b$ signal region after unblinding.

8.2 Unscaled $m_{4j}$ distributions in the 3$b$ signal region after unblinding.

8.3 Unscaled $m_{4j}$ distributions in the 2$bs$ signal region after unblinding.

8.4 Scaled $m_{4j}$ distributions in the 4$b$ signal region after unblinding.
8.5 Scaled $m_{3j}$ distributions in the $3b$ signal region after unblinding.  
8.6 Scaled $m_{3j}$ distributions in the $2bs$ signal region after unblinding.  
8.7 Distributions of $m_{4j}$ in the signal region of the resolved analysis for (a) 2015 data and (b) 2016 data, compared to the predicted backgrounds. The hatched bands shown in the bottom panels represent the combined statistical and systematic uncertainties in the total background estimates. The expected signal distributions of $G_{KK}^+$ resonances with masses of 800 and 1200 GeV, the 280 GeV scalar sample and SM non-resonant di-Higgs production ($\times 100$) are also shown. The scalar sample is normalized to a cross section times branching ratio of 2.7 pb.  
8.8 Local $p_0$ of the (a) scalar, (b) $G_{KK}^+$ with $\epsilon = 1$, and (c) $G_{KK}^+$ with $\epsilon = 2$.  
8.9 The impact of nuisance parameters on the fitted cross section, ranked by their post-fit impact. The signal mass used in these fits is 2000 GeV, and the signal model is (a) narrow scalar, (b) $G_{KK}^+$ with $\epsilon = 1$, and (c) $G_{KK}^+$ with $\epsilon = 2$.  
8.10 Post-fit signal region scaled $m_{3j}$ distributions after fitting the data with the 2 TeV $G_{KK}^+$ with $\epsilon = 1.0$ hypothesis. The signal strength is slightly positive.  
8.11 The expected and observed 95% CL upper exclusion limits for the boosted analysis calculated including all systematic uncertainties for the narrow scalar model. The dot-dashed line shows the expected limit when only statistical uncertainties are included. The limits are derived with the asymptotic approximation.  
8.12 The expected and observed 95% CL upper exclusion limits for the boosted analysis calculated including all systematic uncertainties for the $\epsilon = 1.0$ Graviton. The dot-dashed line shows the expected limit when only statistical uncertainties are included. The limits are derived with the asymptotic approximation.  
8.13 The expected and observed 95% CL upper exclusion limits for the boosted analysis calculated including all systematic uncertainties for the $\epsilon = 2.0$ Graviton. The dot-dashed line shows the expected limit when only statistical uncertainties are included. The limits are derived with the asymptotic approximation.  
8.14 The expected and observed 95% CL upper exclusion limits for the combined analysis calculated including all systematic uncertainties for the narrow scalar model. The dot-dashed line shows the expected limit when only statistical uncertainties are included. The limits are derived with the asymptotic approximation.
8.15 The expected and observed 95\% CL upper exclusion limits for the combined analysis calculated including all systematic uncertainties for the $c = 1.0$ $G_{KK}$. The dot-dashed line shows the expected limit when only statistical uncertainties are included. The limits are derived with the asymptotic approximation.

8.16 The expected and observed 95\% CL upper exclusion limits for the combined analysis calculated including all systematic uncertainties for the $c = 2.0$ $G_{KK}$. The dot-dashed line shows the expected limit when only statistical uncertainties are included. The limits are derived with the asymptotic approximation.

A.1 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the leading large-$R$ jet in data and prediction in the sideband region after requiring 4 $b$-tags.

A.2 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the subleading large-$R$ jet in data and prediction in the sideband region after requiring 4 $b$-tags.

A.3 The first two rows show the $p_T$ of the leading (left) and subleading (right) small-$R$ track jets associated to the lead (first-row) and sublead (second-row) large-$R$ jet in data and prediction in the sideband region after requiring 4 $b$-tags. B.9 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the leading large-$R$ jet in data and prediction in the control region after requiring 2 $b$-tags split. ................................................ 137
B.10 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the subleading large-$R$ jet in data and prediction in the control region after requiring 2 $b$-tags split.

B.11 The first two rows show the $p_T$ of the leading (left) and subleading (right) small-$R$ track jets associated to the lead (first-row) and sub-lead (second-row) large-$R$ jet in data and prediction in the control region after requiring 2 $b$-tags split. The third row shows the $\Delta R$ between two leading small-$R$ track-jets associated to the leading (left) and subleading (right) large-$R$ jet.

B.12 Kinematics (invariant mass, $\Delta R$, $\Delta \eta$ and $\Delta \phi$) of the two large-$R$ jets in data and prediction in the control region after requiring 2 $b$-tags split.

C.1 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the leading large-$R$ jet in data and prediction in the signal region after requiring 4 $b$-tags.

C.2 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the subleading large-$R$ jet in data and prediction in the signal region after requiring 4 $b$-tags.

C.3 The first two rows show the $p_T$ of the leading (left) and subleading (right) small-$R$ track jets associated to the lead (first-row) and sub-lead (second-row) large-$R$ jet in data and prediction in the signal region after requiring 4 $b$-tags. The third row shows the $\Delta R$ between two leading small-$R$ track-jets associated to the leading (left) and subleading (right) large-$R$ jet.

C.4 Kinematics (invariant mass, $\Delta R$, $\Delta \eta$ and $\Delta \phi$) of the two large-$R$ jets in data and prediction in the signal region after requiring 4 $b$-tags.

C.5 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the leading large-$R$ jet in data and prediction in the signal region after requiring 3 $b$-tags.

C.6 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the subleading large-$R$ jet in data and prediction in the signal region after requiring 3 $b$-tags.

C.7 The first two rows show the $p_T$ of the leading (left) and subleading (right) small-$R$ track jets associated to the lead (first-row) and sub-lead (second-row) large-$R$ jet in data and prediction in the signal region after requiring 3 $b$-tags. The third row shows the $\Delta R$ between two leading small-$R$ track-jets associated to the leading (left) and subleading (right) large-$R$ jet.

C.8 Kinematics (invariant mass, $\Delta R$, $\Delta \eta$ and $\Delta \phi$) of the two large-$R$ jets in data and prediction in the signal region after requiring 3 $b$-tags.

C.9 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the leading large-$R$ jet in data and prediction in the signal region after requiring 2 $b$-tags split.
C.10 Kinematics ($p_T$, mass, $\eta$, $\phi$) of the subleading large-$R$ jet in data and prediction in the signal region after requiring 2 $b$-tags split. .................................................. 153
C.11 The first two rows show the $p_T$ of the leading (left) and subleading (right) small-$R$ track jets associated to the lead (first-row) and sub-lead (second-row) large-$R$ jet in data and prediction in the signal region after requiring 2 $b$-tags split. The third row shows the $\Delta R$ between two leading small-$R$ track-jets associated to the leading (left) and subleading (right) large-$R$ jet. .......................................................... 154
C.12 Kinematics (invariant mass, $\Delta R$, $\Delta \eta$ and $\Delta \phi$) of the two large-$R$ jets in data and prediction in the signal region after requiring 2 $b$-tags split. ............................... 155

D.1 $tb$ over $0b \mu_{qcd}$ values evaluated in data, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. .......................................................... 157
D.2 $2b$ over $1b \mu_{qcd}$ values evaluated in data, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. .......................................................... 158
D.3 $2bs$ over $1b \mu_{qcd}$ values evaluated in data, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. .......................................................... 158
D.4 $3b$ over $2b \mu_{qcd}$ values evaluated in data, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. The signal region is blinded. .......................................................... 159
D.5 $4b$ over $2b \mu_{qcd}$ values evaluated in data, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. The signal region is blinded. .......................................................... 159
D.6 $tb$ over $0b \mu_{qcd}$ values evaluated in dijet MC, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. .......................................................... 160
D.7 $2b$ over $1b \mu_{qcd}$ values evaluated in dijet MC, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. .......................................................... 160
D.8 $2bs$ over $1b \mu_{qcd}$ values evaluated in dijet MC, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. .......................................................... 161
D.9 $3b$ over $2b \mu_{qcd}$ values evaluated in dijet MC, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. .......................................................... 161
D.10 $4b$ over $2b \mu_{qcd}$ values evaluated in dijet MC, with the $N_{event}$ weighted mean and the Gaussian fit mean listed. .......................................................... 162
E.1 For $2b$ background estimate: the fits to the ratio of the data in the $1b$ category, of the subleading Higgs candidate $1b$-tagged events’ subleading Higgs candidate distributions (black points), over the leading Higgs candidate $1b$-tagged events’ subleading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet’s leading track jet $p_T$ (middle), and large-$R$ jet’s subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.

E.2 For $2b$ background estimate: the fits to the ratio of the data in the $1b$ category, of the leading Higgs candidate $1b$-tagged events’ leading Higgs candidate distributions (black points), over the subleading Higgs candidate $1b$-tagged events’ leading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet’s leading track jet $p_T$ (middle), and large-$R$ jet’s subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.

E.3 For $3b$ background estimate: the fits to the ratio of the data in the $2b$ category, of the subleading Higgs candidate $2b$-tagged events’ subleading Higgs candidate distributions (black points), over the leading Higgs candidate $1b$-tagged events’ subleading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet’s leading track jet $p_T$ (middle), and large-$R$ jet’s subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.
E.4 For $3b$ background estimate: the fits to the ratio of the data in the $2b$ category, of the leading Higgs candidate $2b$-tagged events’ leading Higgs candidate distributions (black points), over the subleading Higgs candidate $1b$-tagged events’ leading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet’s leading track jet $p_T$ (middle), and large-$R$ jet’s subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.

E.5 For $4b$ background estimate: the fits to the ratio of the data in the $2b$ category, of the subleading Higgs candidate $2b$-tagged events’ subleading Higgs candidate distributions (black points), over the leading Higgs candidate $2b$-tagged events’ subleading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet’s leading track jet $p_T$ (middle), and large-$R$ jet’s subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.

E.6 For $4b$ background estimate: the fits to the ratio of the data in the $2b$ category, of the leading Higgs candidate $2b$-tagged events’ leading Higgs candidate distributions (black points), over the subleading Higgs candidate $2b$-tagged events’ subleading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet’s leading track jet $p_T$ (middle), and large-$R$ jet’s subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.

E.7 Reweighted $2b$ sideband region prediction comparisons. The top row is the $m_{3j}$; the second row is leading large-$R$ jet $p_T$; the third row is the leading large-$R$ jet’s leading track jet $p_T$; and the last row subleading large-$R$ jet’s leading track jet $p_T$. On the left are the distributions before reweighting, and on the right are the distributions after reweighting.
E.8 Reweighted 3$\ell$ sideband region prediction comparisons. The top row is the $m_{3\ell}$; the second row is leading large-$R$ jet $p_T$; the third row is the leading large-$R$ jet's leading track jet $p_T$; and the last row subleading large-$R$ jet's leading track jet $p_T$. On the left are the distributions before reweighting, and on the right are the distributions after reweighting.

E.9 Reweighted 4$\ell$ sideband region prediction comparisons. The top row is the $m_{3\ell}$; the second row is leading large-$R$ jet $p_T$; the third row is the leading large-$R$ jet's leading track jet $p_T$; and the last row subleading large-$R$ jet's leading track jet $p_T$. On the left are the distributions before reweighting, and on the right are the distributions after reweighting.

E.10 Reweighted 2$\ell$ control region prediction comparisons. The top row is the $m_{3\ell}$; the second row is leading large-$R$ jet $p_T$; the third row is the leading large-$R$ jet's leading track jet $p_T$; and the last row subleading large-$R$ jet's leading track jet $p_T$. On the left are the distributions before reweighting, and on the right are the distributions after reweighting.

E.11 Reweighted 3$\ell$ control region prediction comparisons. The top row is the $m_{3\ell}$; the second row is leading large-$R$ jet $p_T$; the third row is the leading large-$R$ jet's leading track jet $p_T$; and the last row subleading large-$R$ jet's leading track jet $p_T$. On the left are the distributions before reweighting, and on the right are the distributions after reweighting.

E.12 Reweighted 4$\ell$ control region prediction comparisons. The top row is the $m_{3\ell}$; the second row is leading large-$R$ jet $p_T$; the third row is the leading large-$R$ jet's leading track jet $p_T$; and the last row subleading large-$R$ jet's leading track jet $p_T$. On the left are the distributions before reweighting, and on the right are the distributions after reweighting.

E.13 Reweighted 2$\ell$ (left column), 3$\ell$ (middle column), and 4$\ell$ (right column) sideband (top row), control (middle row), and signal (bottom row) region prediction comparisons, for MJJ. The Signal region is blinded, and the data distribution is replaced with the non-reweighted background predictions.
E.14 Reweighted $2b$s sideband (top row), control (middle row), and signal (bottom row) region prediction comparisons, for leading Higgs Candidate leading track jet $p_T$ (first column), leading Higgs Candidate subleading track jet $p_T$ (second column), subleading Higgs Candidate leading track jet $p_T$ (third column), subleading Higgs Candidate subleading track jet $p_T$ (fourth column). The signal region is blinded, where the distribution is replaced with the non-reweighted predictions.

E.15 Reweighted $3b$ sideband (top row), control (middle row), and signal (bottom row) prediction comparisons, for leading Higgs Candidate leading track jet $p_T$ (first column), leading Higgs Candidate subleading track jet $p_T$ (second column), subleading Higgs Candidate leading track jet $p_T$ (third column), subleading Higgs Candidate subleading track jet $p_T$ (fourth column). The signal region is blinded, where the distribution is replaced with the non-reweighted predictions.

E.16 Reweighted $4b$ sideband (top row), control (middle row), and signal (bottom row) region prediction comparisons, for leading Higgs Candidate leading track jet $p_T$ (first column), leading Higgs Candidate subleading track jet $p_T$ (second column), subleading Higgs Candidate leading track jet $p_T$ (third column), subleading Higgs Candidate subleading track jet $p_T$ (fourth column). The signal region is blinded, where the distribution is replaced with the non-reweighted predictions.

E.17 Reweighted $2b$s inclusive region prediction comparisons in dijet MC, for leading Higgs Candidate leading track jet $p_T$ (top left), leading Higgs Candidate subleading track jet $p_T$ (top right), subleading Higgs Candidate leading track jet $p_T$ (bottom left), subleading Higgs Candidate subleading track jet $p_T$ (bottom right). $1b$ and reweighted $1b$ distributions are normalized to $2b$s.

E.18 Reweighted $2b$s sideband (top) / control (middle) / signal (bottom) region prediction comparisons, for MJJ. The signal region is not blinded, since it is dijet MC distribution. $1b$ and reweighted $1b$ distributions are normalized to $2b$s.

F.1 Illustration of ZZ and TT signal regions on the 2D $m_{J}^{\text{lead}}, m_{J}^{\text{subl}}$ plane. The white circle in the middle is the blinded real signal region.

F.2 ZZ signal region distribution of $m_J$ (left column) and leading large-R jet mass (right column), for $4b$ (top row), $3b$ (middle row), and $2b$s (bottom row). Only statistical uncertainties are shown.
F.3 TT signal region distribution of $m_{3j}$ (left column) and leading large-R jet mass (right column), for 4$b$ (top row), 3$b$ (middle row), and 2$b$s (bottom row). Only statistical uncertainties are shown.

G.1 2$b$s channel signal region $m_{3j}$ total background (QCD + $t\bar{t}$) predictions with different $t\bar{t}$ MC variations. The different variations agree with the nominal $t\bar{t}$ MC within the statistical uncertainties.

G.2 The shape of $t\bar{t}$ $m_{3j}$ in the sideband region, comparing the 3$b$ shape with that of the 2$b$s, in order to assess the systematic effect of additional $b$-tags changing the dijet mass distribution. The $m_{3j}$ distribution is shown on the left, and the ratio as a function of $m_{3j}$ between 3$b$ and 2$b$s distributions is shown on the right.

G.3 Dijet mass distribution SR prediction fit with several fit ranges (left) and the ratio of nominal to fits with different fit ranges (right) for the 2$b$s (top), 3$b$ (middle) and 4$b$ (bottom) samples.

G.4 Dijet mass distribution SR prediction fit with several fit functions (left) and the ratio between the nominal function fit result and the fit results with different fit functions (right) for the 2$b$s (top), 3$b$ (middle), and 4$b$ (bottom) samples. The additional fit functions are from Table G.1.

H.1 In 1$b$ data, with the low-mass CR variation, new SB and CR $m_{3j}^{lead} - m_{3j}^{subl}$ distributions.

H.2 In 1$b$ data, with the high-mass CR variation, new SB and CR $m_{3j}^{lead} - m_{3j}^{subl}$ distributions.

H.3 In 1$b$ data, with the signal-depletion (small) CR variation, new SB and CR $m_{3j}^{lead} - m_{3j}^{subl}$ distributions.

H.4 In 1$b$ data, with the low-mass SB variation, new SB and CR $m_{3j}^{lead} - m_{3j}^{subl}$ distributions.

H.5 In 1$b$ data, with the high-mass SB variation, new SB and CR $m_{3j}^{lead} - m_{3j}^{subl}$ distributions.

H.6 In 1$b$ data, with the small SB variation, new SB and CR $m_{3j}^{lead} - m_{3j}^{subl}$ distributions.

H.7 In 1$b$ data, with the large SB variation, new SB and CR $m_{3j}^{lead} - m_{3j}^{subl}$ distributions.

H.8 Comparisons of the nominal QCD shape prediction (black) with the results of control and sideband region variations (red). The ratio of the shape from each variation to the nominal shape is shown in the lower panel. The left column shows the relevant distributions for the 4$b$ signal region, the middle column is for the 3$b$ signal region, and the left column is for the 2$b$s signal region. The top row is for the high CR variation, the middle row is for the low CR variation, and the bottom row is for the small CR variation.
H.9 Comparisons of the nominal QCD shape prediction (black) with the results of control and sideband region variations (red). The ratio of the shape from each variation to the nominal shape is shown in the lower panel. The left column shows the relevant distributions for the $4b$ signal region, the middle column is for the $3b$ signal region, and the left column is for the $2b$ signal region. The top row is for the high SB variation, the second row is for the low SB variation, the third row is for the small SB variation and the large row is for the large SB variation.

2.1 LHC nominal and operational parameters ........................................... 21

5.1 Physics objects and their technical names in the boosted analysis. ............. 48

5.2 List of kinematic selection used in the boosted analysis. These cuts are generally efficient for signal events. .......................................................... 49

5.3 The selection efficiency for $G_{KK} \rightarrow hh \rightarrow bbb$ events ($\epsilon = 1.0$) at each stage of the event selection. Uncertainties are the MC stat uncertainty only. ....................... 61

5.4 The selection efficiency for $G_{KK} \rightarrow hh \rightarrow bbb$ events ($\epsilon = 2.0$) at each stage of the event selection. Uncertainties are the MC stat uncertainty only. ....................... 61

5.5 The selection efficiency for $H \rightarrow hh \rightarrow bbb$ events at each stage of the event selection. .......................................................... 62

6.1 Definitions of the signal region, the control region, and the sideband region. .... 65

6.2 Definitions of the QCD background estimation sample for $4b/3b/2bs$. $n_b^{lead/subj}$ stands for the number of $b$-tagged track jets in the leading/subleading large-$R$ jet. ............. 68

6.3 Background scaling parameters ($\mu_{qcd}$ and $\alpha_t$) estimated from fits to the $m_{lead/jet}$ distributions in $4b/3b/2bs$ sideband regions pre-rewriting. $\xi(\mu_{qcd}, \alpha_t) = \frac{Cov(\mu_{qcd}, \alpha_t)}{\sigma_{\mu_{qcd}} \sigma_{\alpha_t}}$. ................. 73

6.4 Definitions of the $tb$ subsamples. ..................................................... 75

6.5 Background scaling parameters ($\mu_{qcd}$ and $\alpha_t$) estimated from fits to the $m_{lead/jet}$ distributions in $4b/3b/2bs$ sideband regions post reweighting. $\xi(\mu_{qcd}, \alpha_t) = \frac{Cov(\mu_{qcd}, \alpha_t)}{\sigma_{\mu_{qcd}} \sigma_{\alpha_t}}$. ................. 76

6.6 Smoothing parameters in $4b$, $3b$, and $2bs$ signal regions for scaled mass distributions, the correlation between parameters is almost always 0.99. ............... 82

6.7 Expected yields for backgrounds in the $4b$ signal region, control region, and sideband region, along with the observed number of data events. The signal predictions for $G_{KK}^m = 1.0, 1.5, 2.0$ TeV with $\epsilon = 1.0$. The uncertainty listed is statistical, without fit uncertainty. .................................................. 84
6.8 Expected yields for backgrounds in the 3b signal region, control region, and sideband region, along with the observed number of data events. The signal predictions for \( G_{KK}^m = 1.0, 1.5, 2.0 \text{ TeV} \) with \( c = 1.0 \). The uncertainty listed is statistical, without fit uncertainty.

6.9 Expected yields for backgrounds in the 2bs signal region, control region, and sideband region, along with the observed number of data events. The signal predictions for \( G_{KK}^m = 1.0, 1.5, 2.0 \text{ TeV} \) with \( c = 1.0 \). The uncertainty listed is statistical, without fit uncertainty.

7.1 Observed data and predictions in 4b control region with statistical uncertainties.

7.2 Observed data and predictions in 3b control region with statistical uncertainties.

7.3 Observed data and predictions in 2bs control region with statistical uncertainties.

7.4 Percent impact of the dominant systematics on the background acceptance and on the signal acceptance of \( G_{KK}^m \) with \( c = 1.0 \) in the 4b channel signal region.

7.5 Percent impact of the dominant systematics on the background acceptance and on the signal acceptance of \( G_{KK}^m \) with \( c = 1.0 \) in the 3b channel signal region.

7.6 Percent impact of the dominant systematics on the background acceptance and on the signal acceptance of \( G_{KK}^m \) with \( c = 1.0 \) in the 2bs channel signal region.

8.1 Unblinded signal region predictions and results. All systematic uncertainties are included for backgrounds. The Poisson uncertainty in data is shown for comparison.

8.2 The number of predicted background events in the signal region for the resolved analysis compared to the data, for the 2015 and 2016 datasets. The yields for three potential signals, an 800 GeV \( G_{KK}^m \) resonance with \( c = 1.0 \), a scalar with a mass of 280 GeV, and SM non-resonant Higgs boson pair production, are also shown. The scalar sample is normalized to a cross section times branching ratio of 2.7 pb. The quoted uncertainties include both the statistical and systematic uncertainties, and the total uncertainty considers correlations. The numbers of observed and predicted events are also given in the control region.

8.3 95% CL exclusion limits for SM non-resonant di-Higgs production, in units of the SM predicted value for \( \sigma(pp \to hh \to b\bar{b}b\bar{b}) \).

C.1 4b unblinded signal region predictions and results. All systematic uncertainties included for backgrounds. For data, the statistical uncertainty is shown. The mass range is broken into greater than 1 TeV, 1.5 TeV, 2 TeV, 2.5 TeV, and 3 TeV intervals.
C.2 3b unblinded signal region predictions and results. All systematic uncertainties included for backgrounds. For data, the statistical uncertainty is shown. The mass range is broken into greater than 1 TeV, 1.5 TeV, 2 TeV, 2.5 TeV, and 3 TeV intervals.

C.3 2b unblinded signal region predictions and results. All systematic uncertainties included for backgrounds. For data, the statistical uncertainty is shown. The mass range is broken into greater than 1 TeV, 1.5 TeV, 2 TeV, 2.5 TeV, and 3 TeV intervals.

C.4 4b unblinded scaled dijet mass signal region predictions and results. All systematic uncertainties included for backgrounds. For data, the statistical uncertainty is shown. The mass range is broken into greater than 1 TeV, 1.5 TeV, 2 TeV, 2.5 TeV, and 3 TeV intervals.

C.5 3b unblinded scaled dijet mass signal region predictions and results. All systematic uncertainties included for backgrounds. For data, the statistical uncertainty is shown. The mass range is broken into greater than 1 TeV, 1.5 TeV, 2 TeV, 2.5 TeV, and 3 TeV intervals.

C.6 2b unblinded scaled dijet mass signal region predictions and results. All systematic uncertainties included for backgrounds. For data, the statistical uncertainty is shown. The mass range is broken into greater than 1 TeV, 1.5 TeV, 2 TeV, 2.5 TeV, and 3 TeV intervals.

F.1 Observed data and background predictions in the ZZ signal regions in 4b, 3b, and 2b channels.

F.2 Observed data and background predictions in the TT signal regions in 4b, 3b, and 2b channels.

To my grandparents and my grandchildren.
First, I want to thank you, the reader, for reading this thesis and acknowledgments now.

I have many people and organizations to thank. Without them I would not have finished this thesis or my Ph.D. in physics. Thanks to:

- Melissa Franklin, the best adviser ever. Every time I get stuck, Melissa is always there to guide me and show me the light at the end of the tunnel. She always pushes me to understand the details I ignore and think about every result I get. I learned how to read, write, plot, think and talk from her. I also learned how to teach physics from working with her in teaching Physical Science 12. Her encouragement, advice, and commentary have always been inspirational and keep me moving ahead.

- Masahiro Morii, for being on my committee, and offering physics guidance and discussions. You have always been insightful.

- Howard Georgi, for being on my committee, and having me teach Physics 16 with you. It is always nice to talk about physics with you.

- João Guimarães da Costa, for your enthusiasm about physics. I have always enjoyed talking about LHC physics with you. You got me interested in di-Higgs and have always been very supportive.

- Paolo Giromini. You taught me how to work on Micromegas, always have great comments on physics and scolding, and ask for the White Rabbits.

xxix
• **John Huth**, for all your support and great stories.

• **The Chinese, the U.S., the French, and the Swiss governments.** Without their generous support, I couldn’t have studied and lived in these different countries.

• **CERN.** CERN is a unique and special place with the streets named after physicists. Without the support from the IT department, I could not log into Lxplus, check the Twikis, or finish my work. CERN user’s office also made traveling to Europe a much nicer and easier experience for me.

• **The LHC.** Without a fully functional accelerator, there would have been no data for me to study. The LHC has performed outstandingly since 2015, and all the data in this thesis is produced from it.

• **Everyone in the ATLAS collaboration.** They have supported this remarkable program and have contributed enormously to my thesis. Without the excellent work on detector design, commissioning, operational work, reconstruction, data processing, performance studies and recommendations, software support, computing support, and analysis discussions and guidance, I could not have completed this thesis. I sincerely thank all ATLAS members for their work.

• **ATLAS Muon experts.** Thanks to Christoph Amelung for his support. Thanks to Ioannis Nomidis, for his guidance on Athena and Muon Monitoring Software. Thanks to Philipp Fleischmann and TieSheng Dai for teaching me about the ATLAS control room and Muon detectors, and for bringing me down to the detector. Thanks to Niels van Eldik, for his guidance on Hough Transform, segment reconstruction and seeding. Thanks to Jochen Meyer, for his patience, help, and discussions on Muon reconstruction and software writing.

• **ATLAS di-Higgs to \(4b\) group.** Thanks to Mel Shochet for his support. Thanks to Michael Kagan, for his guidance, patience, and pushing. Thanks to John Allison, for always doing great and ambitious work. Thanks to David Wardrope, for his help on statistical analysis. Thanks to Jana Schaarschmidt, for finishing the paper. Thanks to Stephane Willocq for asking great questions. Thanks to Qi Zeng, for his help and useful discussions. Thanks to xxx
Patrick Bryant, for doing the equally hard work and finishing the resolved di-Higgs analysis. Without them, I would not have completed the di-Higgs analysis.

- **Harvard ATLAS group post-docs.** I want to thank Alex Tuna, for his patience, help, and kind support in Muon work and di-Higgs analysis. He always gives good advice on talks and on ZERO. I want to thank Pierluigi Catastini, for working on early di-Higgs studies with me in summer 2014; Hugh Skottowe, for his help on Micromegas and C code; David Lopez Mateos, for his discussions on physics and asking for plots and espressos; Chris Rogan, for his passion and great insights in analysis; Valerio Ippolito, for following up on questions; Geraldine Conti, Stefano Zambito, and Larry Lee, for their discussions and help.

- **Stephen Chan,** for his great company as a roommate and awesome-o discussions on ATLAS and physics. He edited this thesis more than his own.

- **Harvard ATLAS graduate students.** Thanks to Tomo Lazovich for being wonderful elder graduate students and work with me on the analysis. Thanks to Emma Tolley for her mulled wine and lemon pudding. Thanks to Karri Di Petrillo for all the adventures and great conversations. Thanks to Ann Wang for being so helpful and not mad at my mocking. I want to also thank Laura Jeanty, Giovanni Zevi Della Porta, Kevin Mercurio, William Spearman, Andy Yen, Brian Clark for their discussions. Thanks to Siyuan Sun for his laughs, Jennifer Roloff and Julia Gonski for the nice conversations. And Gareth Kafka, even though you worked on neutrinos.

- **Harvard ATLAS undergraduate students.** I want to thank Michael Albergo, Gray Putnam, and Jonah Philion, the three undergraduates I have worked with over the past summers. Also thanks to the undergraduate students in my Physics 16, 125, and Physical Science 12 sections.

- **Anna Klales and Lakshminarayanan Mahadevan.** I had wonderful teaching experiences with you in Physical Science 12 and Physics 125.

- **Harvard physics staff.** I want to thank Lisa Cacciabaudo, Carol Davis, Jacob Barandes, Korin Watras, Felice Gardner, and Angela Allen for being extremely helpful and supportive.
• **Caltech and my undergraduate advisers.** Thomas Tombrello, thanks for teaching me how to do research. Stephen Padin, thanks for teaching me how to do an experiment in a lab. Gil Refael, thanks for being a great a friend and great discussions. Harvey Newman, thanks for teaching me EM and special relativity, and all the help and support on my research. And Maria Spiropulu, thanks for show me how exciting particle physics is. Coach Clinton Dodd, for teaching me how to swim and how to start learning. I also want to thank Yi Chen, who taught me a lot when I was a junior on CMS.

• **Ludwig van Beethoven and Gustav Mahler.** Thanks to their great music, which accompanied me through many long nights. Also thanks to Boston Symphony Orchestra, for its affordable tickets and great performances.

• **Chi Feng, Helena Zhang, Peter Koch, Jennifer Hu.** Thanks for being my wonderful friends from Caltech.

• **Xinyu Yang, Chi Zhang, Rundong Ning, Boqi Zhu, Yizhou Jin.** Thanks for being my friends for the past decade since we attended Beijing High School Four.

• **My relatives and other friends.** Thanks to their support and help through the years.

• **Weidong Tong,** my father. You have always been the smartest person I know.

• **Liping Sun,** my mother. You have always been the wisest person I know.

• **Xuyang Ma.** I didn’t find a new particle, but I found you.
It was the best of times, it was the worst of times, it was the age of wisdom, it was the age of foolishness, it was the epoch of belief, it was the epoch of incredulity, it was the season of Light, it was the season of Darkness, it was the spring of hope, it was the winter of despair, we had everything before us, we had nothing before us, we were all going direct to Heaven, we were all going direct the other way. In short, the period was so far like the present period, that some of its noisiest authorities insisted on its being received, for good or for evil, in the superlative degree of comparison only.

Charles Dickens

Introduction

In 2012, the Higgs boson was discovered by the ATLAS and CMS experiments at the LHC. The particle physics community faced a period just like at the beginning of *A Tale of Two Cities*. The Higgs discovery completes the Standard Model and leaves very few experimental clues for physics beyond the Standard Model at the LHC. But with the LHC’s increase in collision energy, it is a great time to search for physics beyond the Standard Model. The newly discovered Higgs boson can be used as a tool in these searches. Higgs boson pair production is particularly interesting. While having a low cross-section in the Standard Model, its production can be modified by new physics in multiple ways. In particular, two Higgs bosons can be produced through heavy particle resonances which give clear signatures at collider experiments.
This search focuses on the dominant $b \rightarrow bb$ decay mode to search for two Higgs bosons production. The “resolved” analysis is used for the Higgs pair in which the Higgs bosons have Lorentz boosts low enough that four $b$-jets can be reconstructed. The “boosted” analysis is used for those two Higgs pair in which the Higgs bosons have higher Lorentz boosts that prevents the Higgs boson decay products from being resolved in the detector as separate $b$-jets. Instead, each Higgs boson candidate consists of a single large-radius jet, and $b$-decays are identified using smaller-radius jets built from charged-particle tracks. The two analyses are complementary in their acceptance, each employing a unique technique to reconstruct the Higgs boson. This thesis focuses on the boosted analysis due to its greater sensitivity to heavy resonance signals.

The dataset for the boosted analysis corresponds to 36.1 fb$^{-1}$ data collected in 2015 and 2016. The results are obtained using the resolved analysis for a resonance mass between 260 GeV and 1400 GeV, and the boosted analysis between 800 GeV and 3000 GeV. The main background is multijet production, which is estimated from data; the sub-leading background is $t\bar{t}$, which is estimated using both data and simulation. The two analyses employ orthogonal selections, and a statistical combination is performed in the mass range where they overlap. The final discriminants are the four-jet and two-jet invariant mass distributions in the resolved and boosted analyses, respectively. Limits are set for the following benchmark signals: a spin-2 graviton decaying into two Higgs bosons, a scalar resonance decaying into two Higgs bosons, and SM non-resonant Higgs boson pair production. In the boosted analysis, the improvements with respect to the preceding ATLAS analysis comes from an additional signal region and novel background estimation techniques.

This thesis begins by discussing the status of di-Higgs searches. Chapter 1 gives an overview of double Higgs production in the Standard Model and beyond. Chapter 2 presents details regarding the Large Hadron Collider and the ATLAS experiment. Chapter 3 discusses reconstruction of physics objects. Chapter 4 lists the dataset and simulation samples. Chapter 5 shows the event sele-
tion. Chapter 6 discusses the background estimation in details. Chapter 7 presents the systematic uncertainties. Finally, the results are shown in Chapter 8. A brief summary and outlook is presented in the conclusion. Many detailed plots and supporting material are shown in the appendices.
The Standard Model and the Higgs boson

The Standard Model (SM)\textsuperscript{1,7,8,9} is a quantum field theory describing the interactions of elementary particles through the strong, weak, and electromagnetic forces. The elementary particles and their properties are shown in Figure 1.1. So far, the SM predictions of particle interactions agree extremely well with almost all experimental observations.

In the SM, the Higgs mechanism introduces a complex scalar Higgs field, $\phi$, with nonzero vacuum expectation values. The scalar Higgs potential is $V(\phi) = -\nu^2 \lambda_\nu \phi^\dagger \phi + \lambda_\nu (\phi^\dagger \phi)^2$. Through spontaneous symmetry breaking, $W^\pm$ and $Z$ bosons acquire their masses. This process also predicts an extra scalar, the Higgs boson. The SM Lagrangian containing Higgs couplings, $\mathcal{L}_\text{Higgs}$, is shown
in Equation 1.1.

\[ \mathcal{L}_{\text{Higgs}} = -\lambda_{hff} f \bar{f} f + \delta V_\mu V^\mu \left( \lambda_{hVV} b + \lambda_{hhVV} b^2 \right) + \lambda_{hh} b^2 + \lambda_{hhh} b^3 + \lambda_{hhhh} b^4 \]  

(1.1)

where

- \( v \approx 246 \text{ GeV} \), is the non-zero expectation value of the Higgs field;
- \( \lambda_v \approx -0.13 \), the coefficient for the quartic potential term, is constrained from Higgs mass;
- \( m_h = \sqrt{2\lambda_v v} = 125.09 \pm 0.24 \text{ GeV} \), is the Higgs mass; this was discovered in 2012\(^{10,11}\);
- \( V = W^\pm \) or \( Z \), \( \delta_W = 1 \), \( \delta_Z = \frac{1}{2} \);
- \( \lambda_{hff} = \frac{m_f}{v} \), is the Higgs to fermion coupling; \( m_f \) is the mass of the fermion;
- \( \lambda_{hVV} = \frac{2m_V^2}{v^2} \), is the Higgs to boson coupling; \( m_V \) is the mass of the boson;
- \( \lambda_{hhVV} = \frac{m_V^2}{v^2} \), is the Higgs-Higgs to boson-boson coupling;
- \( \lambda_{hh} = \frac{m_h}{v^2} \), is the Higgs mass term;
• \( \lambda_{hhh} = \frac{m_h^2}{2v} = \lambda_{h^2} \), or \( \lambda_{hhh} \), is the Higgs self-coupling;

• \( \lambda_{hhhh} = \frac{m_h^2}{8v^2} \), is the Higgs quartic-coupling.

\( \lambda_{hhh} \) in Equation 1.1 has not been experimentally measured. The SM predicts \( \lambda_{hhh} = \frac{m_h^2}{2v} \), which is referred to as \( \lambda_{SM} \) in this thesis. Measuring \( \lambda_{hhh} \) directly probes the quartic term in the Higgs potential. Also, the \( \lambda_{hhh} h^3 \) term enables a double Higgs production channel within the SM. Double Higgs production is also known as di-Higgs or Higgs pair production.

1.2 Standard Model di-Higgs production

There are two main di-Higgs production diagrams at the LHC, both shown in Figure 1.2. In the gluon-gluon fusion process, di-Higgs are produced through a box or a triangle loop. Only the triangle loop Figure 1.2b probes the \( \lambda_{hhh} \). In the triangle diagram, the middle Higgs boson acts as a propagator (off-shell), and the two Higgs bosons in the final state are on-shell. The diagram with an on-shell middle Higgs and two off-shell Higgs bosons in the final state is strongly suppressed. The box and triangle diagrams interfere destructively, which makes the overall production rate smaller than what would be expected in the absence of a \( \lambda_{hhh} \) term.

![Figure 1.2](image_url)

**Figure 1.2:** Leading order Feynman diagrams contributing to di-Higgs production via gluon-gluon fusion, through the Higgs-fermion Yukawa interactions in Figure 1.2a and the Higgs boson self-coupling in Figure 1.2b. Only Figure 1.2b probes \( \lambda_{hhh} \).
Many other different production modes of di-Higgs exist. The Feynman diagrams for VBF production are shown in Figure 1.3. Figure 1.4 compares the cross sections of gluon-gluon fusion, vector boson fusion (VBF), top-pair, $W^{\pm}$, $Z$ and single-top associated di-Higgs production. It shows that gluon-gluon fusion is the dominant production channel for di-Higgs at $pp$ colliders.

![Feynman diagrams](image1)

Figure 1.3: Leading order Feynman diagrams contributing to Higgs pair production via VBF.

![Graph](image2)

Figure 1.4: Total cross sections (y-axis) at the NLO in QCD for the six largest di-Higgs production channels at $pp$ colliders for different energy (x-axis). Gluon-gluon fusion, VBF, top-pair, $W^{\pm}$, $Z$ and single-top associated di-Higgs productions are shown. The thickness of the lines corresponds to the uncertainties added linearly. $H$ refers to the SM Higgs.

For $pp$ collisions at $\sqrt{s} = 13$ TeV, the total cross section for SM di-Higgs production is evaluated at next-to-next-to-leading order (NNLO) with the summation of logarithms at next-to-next-leading-logarithm (NNLL) accuracy and including finite top-quark mass effects at next-to-leading
order (NLO). There are uncertainties from energy scale and parton distributions functions (PDF).

The production cross section, broken down by different production modes, are as follows:

- Gluon gluon fusion: $\sigma_{gg\rightarrow HH} = 33.49^{+4.9\%}_{-6.0\%} \pm 2.1\% \text{ fb}$.
- Vector boson fusion: $\sigma_{VBF\rightarrow HH} = 1.62^{+2.3\%}_{-2.7\%} \pm 2.3\% \text{ fb}$.
- Gluon gluon fusion to Triple-Higgs: $\sigma_{gg\rightarrow HHH} = 0.063^{+0.6\%}_{-0.4\%} \pm 16.1\% \text{ fb}$.

A femtobarn (fb) is a unit of area equal to $10^{-43}$ m$^2$. This means with the full 2015 and 2016 36 fb$^{-1}$ dataset, the SM expectation is around one thousand di-Higgs events and only two triple Higgs events.

1.3 **Beyond the Standard Model di-Higgs production**

The SM has had many successful experimental predictions, yet the Higgs boson mass at 125 GeV requires extreme fine-tuning for radiative corrections$^1$. The presence of new physics at the TeV scale would help solve this unnatural fine-tuning problem.

Beyond the Standard Model (BSM) physics could significantly enhance both resonant and non-resonant production of di-Higgs at the LHC. Non-resonant production generally refers to modifications of the Higgs couplings, either the Higgs self-coupling or the Higgs-top couplings. Resonant production refers to the case when a particle with invariant mass greater than twice the Higgs mass decays directly into two Higgs bosons. Non-resonant and resonant production also translate to different di-Higgs invariant mass distributions at truth level. In the non-resonant case, the invariant mass distribution has no clear peak, whereas in the resonant case, the invariant mass distribution usually forms a peak with a model dependent width.
Figure 1.5: BSM Higgs boson pair production: non-resonant production proceeds through changes in the SM Higgs couplings in Figure 1.5a and Figure 1.5b, resonant production proceeds through Figure 1.5c an intermediate resonance, X. H and h both refers to the SM Higgs.

1.3.1 BSM non-resonant di-Higgs

Enhanced non-resonant Higgs boson pair production is predicted in many models. BSM models featuring direct $t\bar{t}h\bar{h}$ vertices\(^{14,15}\) or new light colored scalars\(^{16}\) could augment the vertex strength, shown as red circles in Figure 1.5. A direct modification of the Higgs self-coupling coefficient in Eq 1.1, from $\lambda_{\text{SM}}$ to $\lambda$ is also possible. This is shown as a green circle in Figure 1.5b.

Figure 1.6: Total cross sections (y-axis) at the LO and NLO in QCD for di-Higgs production channels, at the LHC $\sqrt{s} = 14$ TeV as a function of the self-interaction coupling $\lambda$ (x-axis). The dashed (solid) lines and light- (dark-) color bands correspond to the LO (NLO) results and to the scale and PDF uncertainties added linearly. The SM values of the cross sections are obtained at $\lambda = \lambda_{\text{SM}}$, indicated by the red vertical line. $H$ refers to the SM Higgs.
The non-resonant di-Higgs enhancement is usually described by the di-Higgs cross section ratio between a BSM $\lambda$ coupling scenario and the $\lambda_{SM}$ coupling scenario. $\frac{\lambda}{\lambda_{SM}}$ indicates the ratio between the BSM model $\lambda$ and $\lambda_{SM}$. From SM electroweak measurements, the self coupling term is constrained to $-14 \leq \frac{\lambda}{\lambda_{SM}} \leq 17.4^{17}$. Variations of $\lambda$ have a non-trivial effect on di-Higgs production cross section, shown in Figure 1.6$^{12}$. In the regime of relatively high trilinear coupling, $10 < |\frac{\lambda}{\lambda_{SM}}|$, the interference between the two diagrams is dominated by the trilinear coupling term. A simple limit on $\frac{\lambda}{\lambda_{SM}}$ can be set based on the observed cross section limit.

1.3.2 BSM resonant di-Higgs

Theoretically, it is relatively easy to introduce new heavy resonances that interact with the SM through the Higgs as a mediator. This usually results in resonant di-Higgs production. With the increase in center of mass collision energy from 8 TeV to 13 TeV in Run 2 of the LHC, the production cross section for particles with TeV mass grows dramatically, as shown in Figure 1.7. In the case of a $2$ TeV $M_X$, the cross section gain is almost a factor of 10. Therefore, it is particularly important to focus on resonant searches in the region above 1 TeV.

![Figure 1.7: Parton luminosity ratios as a function of resonance mass, $M_X$, for 13/8 TeV$^2$. 1, 2, and 3 TeV $M_X$ ratios are indicated by red lines. For a $2$ TeV $X$, the luminosity ratio is almost 10.](image)
Resonant Higgs boson pair production is also predicted by many models. Extensions of the Higgs sector, such as two-Higgs-doublet models (2HDM)\textsuperscript{18,19}, propose the existence of a heavy spin-0 scalar $H$ that can decay into two Higgs bosons. The bulk Randall-Sundrum model\textsuperscript{20,21}, which features spin-2 Kaluza-Klein gravitons, $G_{KK}$, could also subsequently decay to pairs of Higgs bosons. These proposed heavy particles, heavy CP-even scalar $H$ and $G_{KK}$, are represented as X in Figure 1.5c. In model dependent searches, based on fixed assumptions of the resonant particles’ branching ratio, other searches for resonances decaying into $VV$ or $t\bar{t}$ are more sensitive compared to di-Higgs searches\textsuperscript{22}. In order to fully constrain the BSM physics production and decay phase space, di-Higgs search results are interpreted in different models, covering both narrow and wide resonances.

The Randall-Sundrum model proposes a five-dimensional warped space-time that contains two manifolds: one where the force of gravity is very strong and a second manifold at the TeV scale corresponding to the known SM sector. The experimental consequence of this theory is a series of widely mass-spaced Kaluza-Klein graviton resonances, $G_{KK}$. In cases where the fermions are localized to the SM manifold, production of gravitons from fermion pairs is suppressed and the primary mode of production of $G_{KK}$ is gluon-gluon fusion. These gravitons further decay to two Higgs bosons, with branching fraction ranging from 6.43\% for gravitons with a mass of 500 GeV to 7.66\% at 3 TeV. Randall-Sundrum models have two free parameters — the mass of the graviton and $\epsilon = k/\mathcal{M}_{pl}$, where $\mathcal{M}_{pl}$ is the reduced Planck mass and $k$ is the curvature scale of the extra dimension. The width of the graviton increases with both mass and $\epsilon$. In Run 1, the $G_{KK}$ with $\epsilon = 1.0$ is excluded by searches in di-boson and di-Higgs channels up to 760 GeV, as shown in Figure 1.8. Therefore, probing the TeV region is promising in the LHC Run 2.

The 2HDM is a simple extension of the SM which has large resonance effects\textsuperscript{13}. The 2HDM consists of 5 physical Higgs bosons: $h$ (light scalar Higgs), $H$ (heavy scalar Higgs), $A$ (heavy pseudoscalar Higgs), and $H^\pm$ (two charged Higgs). The 2HDM can introduce tree level flavor changing
neutral currents. To avoid this obvious contradiction with the SM, models impose discrete symmetries in which the charged fermions only couple to one of the Higgs doublets. One class of such models is type II 2HDM, in which all positively charged quarks couple to one doublet and the negatively charged quarks and leptons couple to the other. The type II model is consistent with the Minimal Supersymmetric Standard Model (MSSM). Resonant di-Higgs production in 2HDM models can proceed through decays of the heavy CP-even Higgs $H \rightarrow bb$. The branching ratio for $H \rightarrow bb$ depends on the model type as well as the values of $\tan \beta$ and $\cos(\beta - \alpha)$. $\tan \beta = \frac{\text{mass of heavy Higgs}}{\text{mass of light Higgs}}$ is the ratio of the vacuum expectation values of the two Higgs doublets. $\alpha$ is the mixing angle between the heavy $H$ and light $b$ fields. The limit where $\cos(\beta - \alpha) = 0$ is called the alignment limit, where the

---

Figure 1.8: Reach of ATLAS searches for new phenomena. Only a representative selection of the available results is shown. Blue (green) bands indicate $\gamma$ TeV (8 TeV) data results.
Figure 1.9: Regions of the $[m_A, \tan\beta]$ plane excluded in the hMSSM model via direct searches for heavy Higgs bosons and fits to the measured rates of observed Higgs boson production and decays. Limits are quoted at 95% CL and are indicated for the data (solid lines) and the expectation for the SM Higgs sector (dashed lines). The light shaded or hashed regions indicate the observed exclusions.

The Higgs boson has a short lifetime of $1.56 \times 10^{-22}$s. It decays into other elementary particles as soon as it is produced in $pp$ collisions. Therefore, searching for di-Higgs productions requires reconstructing the Higgs boson from its decay products. Di-Higgs decay modes is a combination of two single Higgs boson decay modes. The branching ratios of different di-Higgs final states are shown in Figure 1.10.
Figure 1.10: Summary of di-Higgs final states and their ratios. Top left, $bb\bb$, has the largest branching ratio.

Figure 1.11: The observed and expected 95\% CL upper limits of $\sigma(gg \to H) \times BR(H \to hh)$ at $\sqrt{s} = 8$ TeV as functions of the heavy Higgs boson mass, $m_H$, combining resonant searches in Higgs boson pair to $bb\tau^+\tau^-$, $W^+W^-$, $\gamma\gamma$, and $bb\gamma\gamma$ final states. The expected limits from individual searches are also shown. The green and yellow bands represent $\pm \sigma$ and $\pm 2\sigma$ uncertainty ranges of the expected combined limits. The improvement above $m_H = 500$ GeV reflects the sensitivity of the $bb\bb$ analysis. The results beyond 1 TeV are from the $bb\bb$ final state alone.
Previous searches for Higgs boson pair production have not found any significant signals. Using 8 TeV data, ATLAS examined the $b\bar{b}b\bar{b}$, $b\bar{b}\gamma\gamma$, $b\bar{b}\tau^+\tau^-$, and $W^+W^-\gamma\gamma$ channels, all of which were combined. The resonant search combination result is shown in Figure 1.1. The best non-resonant $\sigma(pp \rightarrow hh)$ cross section limit in Run 1 of the LHC is the ATLAS combination, at 0.69 pb. This corresponds to $|\frac{1}{\text{det}}| < 70$. Different di-Higgs search challenges and perspectives are summarized below:

- $b\bar{b}b\bar{b}$: This channel is the most sensitive channel for high mass resonance searches. The $b$-jet trigger efficiency limits the low mass resonance searches, but for high mass resonances above 500 GeV, the branching ratio of this channel provides a decisive advantage. It is sensitive for non-resonant searches as well.

- $b\bar{b}W^+W^-$: This channel has the second largest branching ratio, yet the large background from $t\bar{t}$ limits the search sensitivity.

- $b\bar{b}\gamma\gamma$: This channel benefits from high double photon trigger efficiency, a good photon reconstruction efficiency, and a low SM background. This is more sensitive at resonance masses $m_X \leq 350$ GeV. At higher masses, the smaller branching ratio and the merging of photons hurt the search sensitivity. It is also sensitive for non-resonant searches.

- $b\bar{b}\tau^+\tau^-$: This channel is complimentary between $b\bar{b}b\bar{b}$ and $b\bar{b}\gamma\gamma$ for resonance searches. It contributes to the non-resonant result significantly.

- $W^+W^-\gamma\gamma$: This channel suffers from much lower branching ratio and lower reconstruction efficiency of the $W^+W^-$ compared to $b\bar{b}$.

- $W^+W^-\tau\tau$, $W^+W^-W^+W^-$, $b\bar{b}ZZ$: These channels have not been searched for yet. But because of the large yield and clean leptonic signatures, it is possible that they will be explored in the future.
1.5 Resolved and Boosted

The thesis focuses on searching for a TeV scale resonance \( X \rightarrow hh \rightarrow b\bar{b}b\bar{b} \). The invariant mass of the two-Higgs-boson-candidate system, \( m_{2J} \), is used as the final discriminant between Higgs boson pair production and the SM backgrounds. The Higgs boson reconstruction affects the \( m_{2J} \) invariant mass resolution. Fully reconstructed \( b \)-quarks are also necessary to separate the signal from the multi quark production backgrounds.

When the Higgs bosons have Lorentz low boosts, four small-\( R \) \( b \)-jets with \( R = 0.4 \) can be reconstructed. This final state is called the resolved state, shown on the left of Figure 1.12. The resolved strategy is effective for resonance \( M_X \) from 260 GeV up to 1.2 TeV. The resolved state is also sensitive for non-resonant di-Higgs searches.

A different reconstruction strategy is used for di-Higgs systems with higher Lorentz boosts from heavier resonances. For a Higgs boson produced with momentum \( p_H \), the angular separation between the \( b \) and \( \bar{b} \) quarks, \( \Delta R_{bb} = \sqrt{(\Delta \eta_{bb})^2 + (\Delta \phi_{bb})^2} \), scales roughly as \( \frac{2m_H}{p_H} \). For example, a 1.5 TeV resonance \( G_{KK}^* \) is produced roughly at rest in a \( pp \) collision. In the lab frame, the two Higgs
bosons each have $\sim 625 \text{ GeV}$ momentum. The $\Delta R_{bb}$ is $\sim 0.4$. This means the $b\bar{b}$ system will be contained in two overlapping the standard $R = 0.4$ $b$-jets. The background rejection power is reduced, and the resolved analysis is not sensitive in this case. Therefore, a different analysis strategy is required. Instead, each $b\bar{b}$ system is reconstructed as a single, large-radius jet. The large-radius jet contains the decay products of the Higgs boson. The presence of $b$-quarks is inferred using smaller-radius track jets built from charged-particle tracks. This final state is called the \textit{boosted} state, shown on the right of Figure 1.12. This strategy works for resonance $M_X$ from 1 GeV up to 3 TeV.

In summary, di-Higgs production is very rare in the SM, but could be significantly enhanced in BSM scenarios. In particular, a heavy resonance spin-0 or spin 2 particle could decay into Higgs boson pair directly. The search sensitivity for massive resonances increases as the collision center of mass energy. For resonance signals above 1 TeV decaying into Higgs boson pair, $b\bar{b}b\bar{b}$ channel has the best discovery potential in Run 2. In order to fully reconstruct these $X \rightarrow hh \rightarrow b\bar{b}b\bar{b}$, boosted techniques have to be used. Searching for TeV scale resonant production of di-Higgs $\rightarrow b\bar{b}b\bar{b}$ in the boosted regime is the goal of thesis.
LHC and ATLAS

The Large Hadron Collider (LHC) is a proton-proton ($pp$) collider at the European Organization for Nuclear Research (CERN) laboratory in Geneva, Switzerland \textsuperscript{26}. ATLAS (A Toroidal LHC ApparatuS), CMS (the Compact Muon Solenoid), ALICE (A Large Ion Collider Experiment), and LHCb (Large Hadron Collider beauty experiment) \textsuperscript{27,28,29,30} are the four main experiments. They are located at the interaction points (IPs) of the accelerator. Figure 2.1 shows a schematic of the LHC ring and its experiments.
2.1 The Large Hadron Collider

Protons accelerated around the LHC originate in a red bottle of hydrogen gas. The 25 minute acceleration of the protons from rest to 6.5 TeV is accomplished in multiple steps:

- Electrons are stripped from the hydrogens to create protons;
- A linear particle accelerator, Linac 2, accelerates the protons to 50 MeV;
- The Proton Synchrotron Booster (PSB) accelerates the protons to 1.4 GeV;
- The Proton Synchrotron (PS) accelerates the protons to 25 GeV;
- The Super Proton Synchrotron (SPS) accelerates the protons to 450 GeV;
- The 16.7 kilometer LHC accelerates the protons to the final TeV energies.
The instantaneous luminosity, \( L \left( \text{m}^{-2} \text{s}^{-1} \right) \), at the LHC is defined in Equation 2.1:

\[
L = \frac{n_b N_b f_{\text{rev}} \gamma_r}{4 \pi \varepsilon_n \beta^*} F
\]

(2.1)

In the above Eq2.1:

- \( n_b \) is the number of bunches per beam;
- \( N_b \) is the number of protons per bunch;
- \( f_{\text{rev}} \) is the proton revolution frequency;
- \( \gamma_r \) is the relativistic Lorentz factor for the protons;
- \( \varepsilon_n \) is the normalized transverse beam emittance, or the average beam spread length;
- \( \beta^* \) is the transverse beam size; \( \sigma_{\text{beam}} = \sqrt{\varepsilon \beta^*} \);
- \( F \) is a reduction factor for the angle beams are colliding.

In \( pp \) collisions, the rate of a certain physics process is \( R_{\text{phy}} = L \sigma \), where \( \sigma (\text{m}^2) \) is the cross section.

The instantaneous luminosity can also be written as the ratio of the rate of inelastic collisions to the inelastic cross section \( \sigma_{\text{inel}} \):

\[
L = \frac{R_{\text{inel}}}{\sigma_{\text{inel}}} = \frac{\mu n_b f_{\text{rev}}}{\sigma_{\text{inel}}}
\]

(2.2)

where \( \mu \) is the number of interactions per bunch crossing. For each bunch crossing, there is one main collision used for physics analysis with the highest center of mass energy, and many other lower energy collisions called “pileup” interactions. Larger “pileup” requires higher detector resolution and faster reconstruction techniques.
The main parameters of the LHC beam and performance are shown in Table 2.1. The target peak instantaneous luminosity for both the ATLAS and CMS experiments is \( L = 10^{34} \text{ cm}^{-2} \text{s}^{-1} \), which was already been exceeded in 2016. This is partly due to the improved \( \beta^* \) and \( F \). The number of “pileup” interactions also increases, shown in Figure 2.2.

![Image of Figure 2.2: The luminosity-weighted distribution of the mean number of interactions per bunch crossing for 2015 and 2016 pp collision data at \( \sqrt{s} = 13 \text{ TeV} \).

2.2 A Toroidal LHC Apparatus

The ATLAS experiment at the LHC is a general-purpose particle detector with near $4\pi$ coverage in solid angle and a forward-backward symmetric cylindrical geometry. The ATLAS detector (Figure 2.3) consists of an inner tracking detector (ID) surrounded by a 2.3 m diameter, thin superconducting solenoid providing a 2 T axial magnetic field, electromagnetic (EM) and hadronic calorimeters (HCAL), and a muon spectrometer (MS). Three extra air-core toroid magnets generate the magnetic field in the MS.

![Figure 2.3: A detailed, computer-generated image of the ATLAS detector and its systems.](image)

2.2.1 Coordinate System

ATLAS uses a right-handed coordinate system with its origin at the nominal IP in the center of the detector and the $z$-axis along the beam pipe. The positive $x$-axis points from the IP to the center of the LHC ring; the positive $y$-axis points towards the sky; and the $z$-axis points straight (like bridges) towards the Geneva airport (A side), back from the Charlie’s pub in France (C side). Cylindrical coordinates $(r, \phi)$ are used in the transverse plane, $\phi$ being the azimuthal angle around the
z-axis. The pseudorapidity is defined in terms of the polar angle \( \theta \) as \( \eta = -\ln \tan(\theta/2) \). \( \eta \) is the massless approximation of rapidity \( y = \frac{1}{2} \ln \frac{E+p_z}{E-p_z} \). \( \theta \) is the angle parameterizing special relativity’s boosts along the z-axis. The angular distance is measured in units of \( \Delta R = \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2} \).

The region with \( |\eta| < 1.5 \) is called the “central” region. It consists of the “barrel” elements, which are arranged in a cylindrical fashion around the beam line. In the “endcap” region, with \( |\eta| > 1.5 \), the detector elements are arranged as disks perpendicular to the beam line. The “forward” region of the detector has \( |\eta| > 2.5 \).

2.2.2 Inner Detector

The ID is important for track reconstruction and heavy flavor b-tagging. The ID covers the pseudorapidity range \( |\eta| < 2.5 \). It consists of three sub-detectors: the silicon pixel detector (PIXEL), the silicon microstrip detector (SCT), and the straw-tube transition-radiation tracking detector (TRT). An additional pixel detector layer (IBL) \(^{35} \), positioned at a mean radius of 3.3 cm, was inserted before the Run-2 data-taking and improves the identification of b-jets\(^{36} \). A 10 GeV charged particle in the barrel region will produce 1 IBL hits, 3 PIXEL hits, 8 SCT hits and 36 TRT hits. Figure 2.4a \(^{37} \) shows the R-z distribution of the material for a quadrant of the barrel region PIXEL and SCT. Figure 2.4b shows the distribution of hadronic-interaction vertex candidates in \( |\eta| < 2.4 \) and \( |z| < 400 \) mm for 13 TeV data.

2.2.3 Calorimeters

The calorimeters are important for measuring the energy of the Higgs boson decay productions. A lead and liquid argon (LAr) sampling calorimeter with finely segmented layers provides EM energy measurements. A steel/scintillator-tile hadronic calorimeter covers the central pseudorapidity range (\(|\eta| < 1.7 \) ) and provides hadronic energy measurements. The endcap and forward regions
are instrumented with copper/tungsten and LAr calorimeters, respectively, for both the EM and hadronic energy measurements up to \(|\eta| = 4.9\). The calorimeters also provide basic EM/hadronic trigger information, with fast, analog summing in coarse granularity.

2.2.4 Muon Spectrometer

(a) Cross-section of the muon system in \(R-z\) plane. Numbers indicate different \(\eta\) stations. For MDT letters, B means barrel, and E means endcap. I stands for inner, M for middle, O for outer, and E for extra.

(b) Cross-section of the barrel muon system in \(\phi-y\) plane. Numbers indicate different \(\phi\) stations. Last L means large sectors and last S means small sectors.

Figure 2.5: The overall layout of the ATLAS muon spectrometer.
The muon spectrometer (Figure 2.5) is the largest component of the ATLAS detector. It surrounds the calorimeters and includes three, large superconducting air-core toroids. The field integral of the toroids ranges between 2 and 6 T/m for most of the detector. Because of this bending power, the MS measures muon momentum with $\sigma_{p_T}/p_T \sim 10\%$ at $p_T = 1\text{TeV}$. Muon Drift Tubes (MDT) and Cathode Strip Chambers (CSC) are the precision tracking detectors. Resistive Plate Chambers (RPC) in the barrel and Thin Gap Chambers (TGC) are the triggering detectors, with 1.5-5 ns timing resolution.

2.2.5 Trigger and Data Acquisition

![Cumulative luminosity vs. time delivered to (green) and recorded by ATLAS (yellow) during stable beams for pp collisions at $\sqrt{s} = 13$ TeV.]

A dedicated trigger system is used to select interesting physics collision events. The first-level trigger (L1) is implemented in hardware and uses the calorimeter and muon detectors to seed regions of interest (RoI) and reduce the accepted event rate to 100 kHz. This is followed by a software-based high-level trigger (HLT) that reduces the accepted event rate from 40 MHz to 1 kHz on average. To avoid high rates for certain triggers, the triggers are often prescaled, which means some accepted
events get rejected. For example, a prescale of two means only every second event passing all trigger conditions gets accepted.

Over 2015 and 2016, both the LHC and the ATLAS performed outstandingly. The total data recording efficiency for ATLAS is around 92%, shown in Figure 2.6.
Reconstruction is the process of turning raw detector readouts into particle identification and measurements. In each $pp$ collision recorded by ATLAS, charged particles bend in the magnetic field and leave tracks in the ID; electrons and photons deposit their energies in ECAL; hadrons are absorbed in HCAL; muons leave extra tracks in the MS; and neutrinos are inferred by the conservation of momentum in the transverse plane. Figure 3.1 gives an overview of the different sub-detectors that each type of particle will interact with in ATLAS. Quark reconstruction is particularly important for this $b{ar{b}}b{ar{b}}$ final state analysis.
3.1 ID Tracks and Vertices

Each beam crossing generates multiple track vertices, and the vertices are reconstructed from the available ID tracks. The primary vertex (PV), or the hard-scatter vertex, is selected as the one with the largest $\sum p_T^2$, where the sum is over all associated tracks. The ID tracks are usually required to have at least 1 PIXEL hit and 6 SCT hits, and to be tightly matched to the primary vertex. The tracks are required to have $p_T > 0.4$ GeV and $|\eta| < 2.5$.

The track reconstruction performance is highly dependent on the momentum of the particle. The decay tracks from a highly boosted parent particle have smaller separations in the inner detector, hindering the cluster process, and thus degrading the track identification efficiency. For a 1 TeV $b$-hadron, the reconstruction track efficiency is 83%, compared to 95% for a 200 GeV $b$-hadron.
3.2 Jets

When a quark or gluon is produced in \( pp \) collisions, it produces a collimated spray of hadrons, which is known as a jet\(^{40}\). Jets are built from topological clusters of energy deposits in calorimeter cells\(^{41}\), using a four-momentum reconstruction scheme with massless clusters as input. The directions of jets are corrected to point back to the primary vertex. Typically, jets are reconstructed using the anti-\( k_t \) algorithm\(^{42}\) with different values of the radius parameter, \( R \). This algorithm favors clusterings that involve hard particles, and the jets grow outwards around hard “seeds”. \( R \) appears in the denominator of the clustering distance metric. It determines the radial size of the jet in \( \eta-\phi \) plane. The standard \( R = 0.4 \) jets are used for \( b \)-quark reconstruction in the resolved topology. The large \( R = 1.0 \) jets are used for Higgs boson reconstruction in the boosted topology. The small fixed \( R = 0.2 \) track jets are used for \( b \)-quark identification inside the large-\( R \) jets.

3.2.1 Small-\( R \) Jets

The jets with \( R = 0.4 \) (“small-\( R \) jets”) are reconstructed from clusters calibrated at the electromagnetic (EM) scale. The jets are corrected for additional energy deposited from pile-up interactions using an area-based correction\(^{43}\). They are then calibrated using \( p_T \)- and \( \eta \)-dependent calibration factors derived from simulation, before global sequential calibration\(^{44}\) is applied, which reduces differences in calorimeter responses to gluon or quark-initiated jets. The final calibration is based on in situ measurements in collision data\(^{45}\).

Small-\( R \) jets are required to be consistent with the primary vertex, in order to avoid contamination from pileup interactions. The jet vertex fraction (JVF) is a useful variable for this purpose. It is the ratio of tracks associated with a primary vertex to the total number of tracks inside a jet. Jets from the PV should have most tracks consistent with the PV and therefore have a large JVF value.
3.2.2 LARGE-\(R\) JETS

![Figure 3.2](image)

Figure 3.2: Two collision events recorded in June 2015 with a high leading jet \(p_T\) shown in pseudorapidity-azimuthal angle parameter space. The dots are calorimeter-cell clusters with positive energy. Only the two leading jets are shown, with their area demarcated by a colored circle, with gray regions denoting the corresponding \(k_T\) sub-jets of size \(R_{\text{sub}} = 0.2\). The color of both jets and clusters corresponds to their \(p_T\).

The jets with \(R = 1.0\) ("large-\(R\) jets") are built from locally calibrated\(^{44}\) topological clusters. Two examples are shown in Figure 3.2\(^{45}\). Large-\(R\) jets are trimmed\(^{47}\) to minimize the impact of contamination from non-perturbative effects associated with beam-remnants ("pile-up" events). Trimming proceeds by re-clustering the jet with the \(k_T\) algorithm\(^{48}\) into \(R_{\text{sub}} = 0.2\) sub-jets and then removing those sub-jets with \(p_{T\text{sub}}/p_{T\text{jet}} < 0.05\), where \(p_{T\text{sub}}\) is the transverse momentum of the sub-jet and \(p_{T\text{jet}}\) that of the original jet. Trimming improves the jet mass resolution, as shown in Figure 3.3 and 3.4\(^{49}\). The trimming parameter choices shown here are \(R_{\text{sub}} = 0.1, 0.2, \) and 0.3 for a fixed cut at 5%. The energy and mass scales of the trimmed jets are then calibrated using \(p_T\)- and \(\eta\)-dependent calibration factors derived from simulation\(^{50}\).
Figure 3.3: For the trimming algorithm using calorimeter cell clusters as inputs to the anti-$k_t$ jet reconstruction algorithm with $R = 1.0$, a comparison of the jet mass distribution for QCD background jets and $W$ boson jets low $p_T$ kinematic regions, as determined by the untrimmed truth jet $p_T$.

Figure 3.4: For the trimming algorithm using calorimeter cell clusters as inputs to the anti-$k_t$ jet reconstruction algorithm with $R = 1.0$, a comparison of the jet mass distribution for QCD background jets and $W$ boson jets high $p_T$ kinematic regions, as determined by the untrimmed truth jet $p_T$. 
The calorimeter-based jet mass \( m_{\text{calo}} \) for a large-radius calorimeter jet \( J \) is computed from the calorimeter cell cluster constituents \( i \) with energy \( E_i \) and momentum \( p_i \):

\[
m_{\text{calo}} = \sqrt{\left( \sum_{i \in J} E_i \right)^2 - \left( \sum_{i \in J} \vec{p}_i \right)^2}.
\]  

(3.1)

Tracking information is used to improve the mass resolution. The track-assisted jet mass, \( m^{TA} \), is defined as:

\[
m^{TA} = \frac{p_{\text{calo}}^T}{p_{\text{track}}^T} \cdot m^{\text{track}}.
\]  

(3.2)

where \( p_{\text{calo}}^T \) is the transverse momentum of the large-\( R \) calorimeter jet, \( p_{\text{track}}^T \) is the transverse momentum of the four-vector sum of tracks associated to the large-\( R \) calorimeter jet, and \( m^{\text{track}} \) is the invariant mass of this four-vector sum. This ratio corrects for charged-to-neutral hadron fluctuations and therefore improves the resolution with respect to track-only jet mass.

The above two jet mass definitions are only weakly correlated with each other, so they can be linearly combined to the combined mass, \( m^{\text{comb}} \), by weighting the components with \( w \):

\[
m^{\text{comb}} = w \cdot m_{\text{calo}} + (1 - w) \cdot m^{TA}.
\]  

(3.3)

where \( w \) is determined for each large-\( R \) jet from the resolution functions of the calibrated track and calo mass terms. This results in a smaller mass resolution and better estimate of the median mass value than obtained using only calorimeter energy clusters, as shown in Figure 3.5.

3.2.3 Track Jets

Track jets are essentially clustered charged hadron tracks. They are reconstructed from ID tracks using the anti-\( k_T \) algorithm with a fixed \( R = 0.2 \). Once the track jet axis is determined, an extra
step of track association is performed to select tracks with looser impact parameter requirements, in order to collect the tracks needed for effectively running the $b$-tagging algorithms. Only track jets with at least two tracks are kept. Track jets are also required to have $p_T > 10$ GeV and $|\eta| < 2.5$, in order to suppress light flavor track jets.

Track jets are associated to large-$R$ jets using Ghost-Association. “Ghosts” are track jet 4-vectors, with each track jet’s $p_T$ set to an infinitesimal amount, essentially keeping only the direction of the 4-vector. This ensures that the large-$R$ jet reconstruction is not altered by the ghosts when the calorimeter clusters plus ghosts are reclustered. Re-clustering is then performed using the anti-$k_t$ algorithm with $R = 1.0$. The calorimeter jets after re-clustering are identical to the parents of the trimmed jets used in this analysis, with the addition of the associated track jets retained as constituents. In addition, the track jets corresponding to the ghosts that survive the trimming pro-
procedure (and thus are clustered into one of the surviving sub-jets) are the track jets ghost-associated to the trimmed jet. The small radius parameter of the track-jets enables two nearby $b$-hadrons to be identified when their $\Delta R$ separation is small, which is beneficial when reconstructing high-$p_T$ Higgs boson candidates.

### 3.3 Flavor Tagging

Some jets are formed from quarks with different flavors. Identifying the flavor of the jet parent quark is called flavor tagging. Jets originating from $b$-quarks are referred as $b$-jets, from $c$-quarks is referred as $c$-jets, and from other quarks other than the $t$-quark are referred as light jets. $b$-tagging is particularly useful for this analysis, since there are four $b$-quarks in the final state.

$B$-hadrons have a lifetime, $\tau$, on the order of $1.5 \times 10^{-12}$ seconds, which gives a flight path length $c\tau \sim 0.45 \text{ mm}$ without significant boost. The mean flight path is $\beta\gamma c\tau$, where $\beta = \frac{v}{c}$ and $\gamma$ is the Lorenz factor. With a higher boost, like $p_T = 50$ GeV, the average transverse displacement is $\text{3 mm}$. This results in a displaced decay vertex that can be identified in vertex reconstruction. This allows $b$-jets with sufficient transverse boost to be distinguished from other flavors of jets.

ATLAS uses three different basic $b$-tagging algorithms, which provide complementary information:

- **Impact parameter based algorithm:** this algorithm uses the signed transverse and longitudinal impact parameters $d_0$ and $z_0\sin\theta$ of the tracks inside a jet to determine their consistency with the primary vertex. The algorithm uses simulated templates of $\frac{d\sigma}{d_0}$ and $\frac{d\sigma}{d_0}\sin\theta$ for light, $c$, and $b$ jets to evaluate the likelihood of the jet coming from each of these types.

- **Secondary vertex (SV) reconstruction algorithm:** this algorithm uses tracks inside the jet to look for vertices that are displaced from the primary vertex. The algorithm provides information on the invariant mass of tracks pointing to a displaced vertex, the number of two track vertices, and the angular separation between the jet axis and the PV $\rightarrow$ SV direction.
fraction of jets which have a reconstructed secondary vertex are shown in Figure 3.6a. The increase of tracks from fragmentation in the high $p_T$ region is the main reason for the performance degradation. The number of fake vertices is increasing with jet $p_T$ in light jets, while the secondary vertex reconstruction efficiency for $b/c$-jets slightly decreases with jet $p_T$.

- Decay chain multi-vertex reconstruction algorithm, or JetFitter (JF): this algorithm reconstructs the full flight path of the $b$-hadron by looking for multiple displaced vertices along the same direction. A Kalman filter is used to find a common trajectory for the $b$ and $c$ vertices, and hence the algorithm exploits the topology of the weak $b/c$-hadron decay chain. Leptonic decays of $b/c$ are not considered.

![Graphs](atlas_simulation_preliminary.png)

(a) SV reconstruction rate vs. jet $p_T$.
(b) MV2c10 BDT output for different jets.

Figure 3.6: Secondary vertex reconstruction rate and MV2c10 output for $b$-jets (solid blue), $c$-jets (dashed green) and light-jets (dotted red) evaluated with simulated $t\bar{t}$ events.

Jets containing $b$-hadrons are identified using a score value computed from a boosted decision tree (BDT) algorithm MV2c10, which makes use of observables provided by the three algorithms above. A BDT consists of a forest of decision trees. A number of individual decision trees are trained sequentially, with a boosting process in between each training. Boosting adjusts the weights of individual events depending on whether the previously trained tree classifies them correctly. The MV2c10 algorithm is trained on a $t\bar{t}$ sample, with $b$-jets as signal and a mixture of 93% light-jets and
7% c-jets as backgrounds. It is applied to a set of charged-particle tracks that satisfy quality and impact parameter criteria and are matched to each jet. The MV2c10 algorithm works on both small-\(R\) jets or track jets.

The \(b\)-tagging working point (wp) is a fixed cut on the MV2c10 value that lead to an efficiency of 70% for \(b\)-jets with \(p_T > 20\) GeV when evaluated in a sample of simulated \(\tau\tau\) events. This working point corresponds to an acceptance rate of light-jets or jets originating from gluons at \(\frac{1}{380}\) for the jets with \(R = 0.4\) and \(\frac{1}{120}\) for the track jets. The acceptance of jets from \(c\)-quarks is \(\frac{1}{12}\) for the \(R = 0.4\) jets and \(\frac{1}{7}\) for the track jets.

![Figure 3.7: \(b\)-jet efficiency for the fixed cut working point with a \(b\)-jet efficiency of 77% as a function of jet \(p_T\) for the comparison between the MV2c10 \(b\)-tagging algorithm employed for the 2016 analyses (2016 config) and the previous version of the tagger, MV2c20 (2015 config), which has 15% \(c\)-fraction in the training.](image)

Figure 3.7: \(b\)-jet efficiency for the fixed cut working point with a \(b\)-jet efficiency of 77% as a function of jet \(p_T\) for the comparison between the MV2c10 \(b\)-tagging algorithm employed for the 2016 analyses (2016 config) and the previous version of the tagger, MV2c20 (2015 config), which has 15% \(c\)-fraction in the training.
In this thesis, the track-jets have a wide $p_T$ ranges, between $10 - 400$ GeV, and the same working point leads to $b$-tagging efficiencies varying from 40% at low $p_T$, to 80% for $p_T$ values of about 150 GeV, to 60% at high $p_T$. This can be seen in Figure 3.7, and the $b$-tagging efficiency varies from 60% to 80% for an average efficiency of 77%. The increase of tracks from fragmentation in the high jet $p_T$ region is the main reason for the performance degradation. As the jet $p_T$ increases, the number of vertices from the random combination of high multiplicity tracks is increasing, while the secondary vertex reconstruction efficiency for $b$ and $c$-jets decreases with jet $p_T$. This is shown in Figure 3.8, and the light-jet acceptance rate could range from $\frac{1}{120}$ to $\frac{1}{250}$. This non-trivial jet $p_T$ dependence of $b$-tagging performance is one of the major challenges of this analysis.

Correction factors are applied to the simulated MC samples to compensate for differences between data and simulation in the $b$-tagging efficiency for $b$, $c$ and light-jets. The correction for $b$-jets is derived from $t\bar{t}$ events with final states containing two leptons, and the corrections are consistent.
with unity with uncertainties at the level of a few percent over most of the jet $p_T$ range.

3.4 Leptons

Muons are identified by matching ID tracks with reconstructed MS tracks\textsuperscript{12}. For this thesis, muons must have $p_T > 4$ GeV, $|\eta| < 2.5$ and to satisfy “medium” muon identification criteria\textsuperscript{12}. Muons are used in this thesis because $b$ hadrons decay to muons with $\sim 20\%$ probability. This is described in section 5.3.
4.1 Data

This analysis uses 2015 and 2016 LHC $pp$ collision datasets at $\sqrt{s} = 13$ TeV recorded by the ATLAS experiment. Data were collected during stable beam conditions and when all relevant detector systems were functional. A Good Run List (GRL) is generated after gathering on-line and off-line data quality reviews of the dataset after reconstruction. Typically, any > 10% defect in any detector subsystem makes the corresponding Lumiblocks (LB) fail the GRL requirement. The integrated luminosity of the 2015 dataset passing the GRL requirement is 3.2 fb$^{-1}$, and the 2016 dataset passing the GRL requirement is 32.9 fb$^{-1}$. These values are 82% and 92% of the data ATLAS recorded, respectively, as shown in Figure 2.6.
In the resolved analysis, a combination of three $b$-jet triggers is used:

- “2b4j”: this trigger requires two $b$-tagged jets and two non-$b$-tagged jets, all with $p_T > 35$ GeV. This trigger is most sensitive for resonance mass between 260 GeV and 500 GeV.

- “2b3j”: this trigger requires two $b$-tagged jets with $p_T > 55$ GeV, and one non-$b$-tagged jet with $p_T > 100$ GeV. This trigger is efficient for resonance mass above 600 GeV.

- “1b1j”: this trigger requires one $b$-tagged jet with $p_T > 225$ GeV.

Due to a change in the on-line $b$-tagging algorithm between 2015 and 2016, the two datasets are treated independently until they are combined in the final statistical analysis. After the resolved selection described later, this combination of triggers is estimated to be 65% efficient for simulated signals with mass above 280 GeV, rising to 95% efficiency for resonance masses greater than 600 GeV, as shown in Figure 4.1.

![Figure 4.1: Trigger efficiencies following the full resolved analysis selection as a function of the resonance signal mass. The efficiencies of the triggers used in 2015 and 2016 are shown. In both graphs, the green line shows the efficiency of the “2b4j” trigger; the blue line represents the “2b3j” trigger; the red line represents the “1b1j” trigger. The 2016 triggers are less efficient due to a bug in the online primary vertex reconstruction.](image-url)

During 2016 data-taking, a fraction of the data was affected by a bug. The movement of the beam spot was not accounted for in the on-line vertex reconstruction. This reduced the efficiency of the algorithms used to identify $b$-jets. That fraction of data is not used and this reduces the integrated luminosity of the 2016 dataset for the resolved analysis to 24.3 fb$^{-1}$. 
In the boosted analysis, events were selected from the 2015 dataset using a trigger that required a single anti-$k_t$ jet with radius parameter $R = 1.0$ and with $p_T > 360$ GeV. In 2016, a similar trigger was used but with a higher threshold of $p_T > 420$ GeV. The efficiency of these triggers is 100% for simulated signals passing the jet requirements as described later, so the 2015 and 2016 datasets were combined into one dataset.

The data is further skimmed (removing objects) into the Derived Analysis Object Data (DAOD). The ATLAS off-line software 20.7.8.7 derivation cache is used, with version $p$-tags $p2950$. The boosted slimming (removing events) keeps events with at least two large-$R$ jets with $p_T > 200$ GeV. The final input data file has name format:

\[ \text{dataYR}_{13}\text{TeV}.\text{periodPR}.\text{physics}_\text{Main.} \text{PhysCont.} \text{DAOD}_\text{EXOT8.gr}p\text{YR_}v01_{p2950}, \]

where YR is 15 and PR is [DEFGHJ] for 2015 data, and YR is 16 and PR is [ABCDEFGIKL] for 2016 data.

4.2 MC

All Monte Carlo (MC) samples used in this analysis are produced with full ATLAS detector simulation. For all simulated samples, charm-hadron and bottom-hadron decays were handled by EvtGen 1.2.0\textsuperscript{[13]}\textsuperscript{53}. To simulate the impact of multiple low momentum $pp$ interactions that occur within the same or nearby bunch crossings, minimum-bias events generated with PYTHIA 8\textsuperscript{[34]} were overlaid on the hard-scatter event. This pile-up effect is simulated with a $\mu$ of 25. Although this is different from the pile-up level in data, it has little effect on the analysis, so the pile-up reweighting is not adopted. The detector response was simulated with GEANT 4\textsuperscript{[36,37]}, and the events were processed with the same reconstruction software as that used for the data. Simulated data samples from the ATLAS MC15c campaign are be used, corresponding to $p$-tags $p2952$-$p2949$. 

41
4.2.1 **Signal**

In all signal samples, the mass of the Higgs boson ($m_H$) was set to 125 GeV. The signal MC contains truth-level information, such as the two Higgs and the $b$-quark four-momenta before detector interactions. This enables a $\Delta R$ truth matching between the reconstructed objects and the Higgs.

SM non-resonant production of Higgs boson pairs via the gluon–gluon fusion process was simulated at NLO with `MG5_aMC@NLO`, using form factors for the top-quark loop from HPAIR\(^{58,59}\). The simulated events are reweighted to reproduce the $m_{hh}$ spectrum obtained\(^{60,61}\). This spectrum is calculated at NLO in QCD while fully accounting for the top-quark mass. Interference effects between di-Higgs resonant production and SM non-resonant di-Higgs production are not included in the simulated samples.

Signal $G_{KK}^+ \to bb \to b\bar{b}b\bar{b}$ events were generated at leading order (LO) with `MG5_aMC@NLO`\(^{2.2.2}\) interfaced with `Pythia` 8.186 for parton-showering, hadronization and underlying-event simulation. The NNPDF2.3 LO parton distribution function (PDF) set\(^{63}\) was used for both `MG5_aMC@NLO` and `Pythia`. The A14 set of tuned underlying-event parameters was used. These signal samples were generated with $k/M_\text{Pl} = 1$ or 2. Relative to the resonance mass, widths of the graviton signals range from 3% (at low mass) to 13% (at the highest mass) for $k/M_\text{Pl} = 1$, and 6% to 25% for $k/M_\text{Pl} = 2$. The graviton samples were normalized using fixed cross sections\(^{64}\).

Signal 2HDM Scalar $\to HH \to b\bar{b}b\bar{b}$ events were generated at LO in QCD with `MG5_aMC@NLO` 2.2.3 interfaced with `Herwig++`\(^{65}\) for parton-showering, hadronization, and simulation of the underlying event. CT10\(^{66}\) PDF sets were used for `MG5_aMC@NLO` and `CTEQ6L1`\(^{67}\) for `Herwig++`. The UE-EE-5-CTEQ6L1 set of tuned underlying-event parameters\(^{68}\) was used. The scalar signals were generated with a width of 1 GeV, which represent generic, narrow-width scalar signals. Because the
width and branching ratios depend on 2HDM parameters, each mass point generated with this fixed
width corresponds to a different point in the 2HDM parameter phase space.

Resonant signal samples for the scalar and $k/M_{Pl} = 1$ models were produced in 10 GeV steps
between 260 and 300 GeV, in 100 GeV steps up to 1600 GeV, in 200 GeV steps up to 2000 GeV, and
in 250 GeV steps up to 3000 GeV. Signal samples for the $k/M_{Pl} = 2$ model were produced with
the same spacings but omitting the masses of 270 GeV, 290 GeV, and 2750 GeV due to the larger
generated width. Unless specified, the MC signal sample used as benchmark is $k/M_{Pl} = 1 G_{KK}$,
since its width is medium among the three signal models.

4.2.2 Backgrounds

A very small fraction of the background arises from $Z + \text{jets}$ events. The $Z + \text{jets}$ sample was generated using Pythia 8.186 with the NNPDF2.3 LO PDF set.

The $t\bar{t}$ background is modeled using large all-hadronic and non-all-hadronic samples that have both been generated with Powheg-box v1 using the CT10 PDF set. The parton shower, hadronization, and the underlying event were simulated using Pythia 6.428 with the CTEQ6L1 PDF set and the corresponding Perugia 2012 set of tuned underlying-event parameters. The $t$-quark mass in both samples is set to 172.5 GeV. Higher-order corrections to the $t\bar{t}$ cross section were computed with Top++ 2.0. These incorporate NNLO corrections in QCD, including re-summation of NNLL soft gluon terms. The $t\bar{t}$ MC samples are normalized to the NNLO+NLL predicted inclusive $t\bar{t}$ cross-section of 1821.87 pb multiplied by the all-hadronic branching ratio of 0.457 and non-all-hadronic of 0.543.

In order to minimize statistical fluctuations across the dijet invariant mass spectrum, especially for large values of $m_{in}$, additional $t\bar{t}$ samples are generated in slices of $t\bar{t}$ invariant mass. The cross-
section of the $t\bar{t}$ process is normalized to NNLO+NNLL in QCD, as calculated by Top++ 2.0. Overlap with the inclusive $t\bar{t}$ samples is removed by a fixed cut on the truth value of $m_{tt}$ at 1100 GeV.

A Pythia dijet sample is used to understand the multi-jet background and characteristics of the event selection. This MC sample is generated without a heavy flavor filter, and hence is limited by the total generated number of events, given the high background rejection of the analysis selection.
A finely crafted blade will never meet as many blows on the battlefield as it did on the anvil.

5

Event Selection

An \( X \rightarrow hh \rightarrow b \bar{b} b \bar{b} \) boosted event candidate observed in 2015 data is shown in Figure 5.1. There are 2\( b \) tagged tracks within each of the large-\( R \) jets. The one large-\( R \) jet has 119 GeV mass and 543 GeV\( p_T \), and the other one has 127 GeV mass and 413 GeV\( p_T \). The \( \Delta R \) between the two large-\( R \) jet is 3.54 and the invariant mass of the two large-\( R \) jets is 1336 GeV. This chapter explains why and how this event is selected as an \( X \rightarrow hh \rightarrow b \bar{b} b \bar{b} \) candidate.

5.1 Data Cleaning

The following data cleaning requirements are made:

- Events with problems in SCT/TileCal/LAr are removed.
Figure 5.1: 2015 ATLAS boosted di-Higgs event candidate’s event display. The data is taken in run 282712, lumiblock 503 and has event number 595661746. ID is in gray, ECAL is in green, HCAL is in red and MS is in blue. Only tracks with $p_T > 25$ GeV are shown. Jets are gray cones, and ID tracks are colored lines in the ID.

- Events that fail the jet cleaning procedure are removed. This is designed to exclude jets caused by detector noise, non-collision background, and cosmic rays.
- Incomplete events are removed.

The analysis also runs over the debug stream, which contains events recorded that could not be reconstructed on-line due to CPU time constraints. No event passing the full signal selection is found.

5.2 Trigger

Events in data and MC are required to pass the lowest unprescaled large-$R$ jet trigger:
Figure 5.2: Different trigger efficiencies as a function of the resonance signal mass with respect to all events without additional selections (left) and with respect to events passing the two large-$R$ jets and leading (subleading) jet $p_T > 400 (250)$ GeV (right).

HLT_j360_a10_lcw in 2015 and HLT_j420_a10_lcw in 2016, where LCW stands for locally clustered weighted. The triggered jets are topo-cluster jets with local calibration weights and pile-up subtraction. They are seeded by the lowest unprescaled L1 jet trigger, L1_J100. LCW cluster triggers are chosen, because the alternative option, reclustered large-$R$ jet trigger, has a slower jet momentum turn-on in multi-jet events. Other options such as the lowest unprescaled transverse energy trigger, HLT_ht1000, have a much slower turn-on compared to large-$R$ jet triggers. Another trigger option is a four jet trigger HLT_4j100, but because of boosted jet merging, the trigger efficiency decreases rapidly as the signal mass increases. The trigger efficiencies with respect to all events and events with two large-$R$ jets are shown in Figure 5.2. For 1.4 TeV signal with two large-$R$ jets, the large-$R$ jet trigger efficiency is about 98%. The trigger turn-on curve in 2015 and 2016 data, as a function of leading jet $p_T$, is shown in Figure 5.3. Based on this figure, the large-$R$ jet $p_T$ is required to be above 450 GeV, which is above the trigger turn-on threshold.
Figure 5.3: Large-\( R \) jet trigger (HLT\_j360\_a10\_lcw, left and HLT\_j420\_a10\_lcw, right) efficiencies with respect to the large-\( R \) jet \( p_T \), defined as the ratio between events that fired the trigger and the all the simulated events, measured in 2015 and 2016 data and \( G_{KK}^\epsilon \) with \( \epsilon = 1.0 \) MC.

5.3 Object Selection

The specific physics objects used in the boosted analysis are described in previous sections and reiterated in Table 5.1. The selection cuts are listed in Table 5.2 and are explained in detail.

Each event must have at least two high momentum large-\( R \) jets, defined in section 3.2.2. They are sorted by \( p_T \). The leading large-\( R \) jet, also referred to as the leading Higgs candidate (lead\( J \)), is

Figure 5.4: Percentages of truth Higgs boson contained by a large-\( R \) jet with \( \Delta R_{\text{Higgs, jet}} < 1.0 \) as a function of \( G_{\text{KK}} \) masses. The three cases listed in the legend are orthogonal. Two Higgs bosons almost never match to the same large-\( R \) jet.
defined to be the large-\(R\) jet with the highest \(p_T\). The second highest \(p_T\) large-\(R\) jet is called the sub-leading large-\(R\) jet, also referred to as the subleading Higgs Candidate, or subl\(J\). The large-\(R\) jets are required to have \(p_T > 250\) GeV, \(\mid \eta \mid < 2\) to guarantee the tracking acceptance, and mass > 50 GeV to reduce the size of data and simulations. The leading large-\(R\) jet is also required to have \(p_T > 450\) GeV to be above the trigger turn on threshold. Only the leading and subleading large-\(R\) jets are considered in the rest of this thesis. Both truth-level Higgs bosons are matched to the two large-\(R\) jets \(\sim 95\%\) of the time for 1.2 TeV signal MC, shown as the red curve in Figure 5.4. Requiring \(R = 1.0\) ensures that the two \(b\) quarks and their decay products are very likely to be contained within the large-\(R\) jet, as shown in Figure 5.5.

The track jets, defined in section 3.2.3, are required to have \(p_T > 10\) GeV, \(\mid \eta \mid < 2.5\) and at least two associated tracks. A track jet is considered \(b\)-tagged if it has \(MV_{2\tau 0} > 0.6455\) (see Section 3.3 for details). Each large-\(R\) jet is required to have at least one ghost-associated track jet. Allowing only one ghost-associated track jet is motivated by the kinematic signatures of signals with masses above
2.5 TeV, where the resulting $R = 0.2$ track jets merge due to large Lorentz boosts. If there is more than one track jet contained in the large-$R$ jet, they are also sorted by $p_T$. The highest $p_T$ track jet is defined to be the leading track jet, and the second highest $p_T$ one is defined to be the subleading track jet. Only the two leading $p_T$ track jets are considered in this thesis. One or two track jets are $\Delta R$ matched to the truth $b$ quarks 80% of the time, as shown in Figure 5.6. In the Figure, red means the truth Higgs doesn’t match the large-$R$ jet. Blue means both truth $b$s match the two track jets. Orange means two truth $b$s match the same track jet. Green indicates one $b$ quark has $\Delta R < 0.2$ for both the leading and subleading track jets, and the other $b$ is matched to one of the two track jets. Pink means one $b$ matches to one of the two track jets, while the other $b$ doesn’t match to the two leading track jets.

![Graph](image1)

![Graph](image2)

Figure 5.6: Percentage of $\Delta R < 0.2$ matching truth $b$'s to track jets (leading Higgs on the left, subleading Higgs on the right) for different $G_{KK}$ masses. The cases listed in the legend are orthogonal to each other. The cases not listed on the legend (including when a truth $b$ is not contained in the large-$R$ jet) happen in total at most 1.6% of the total for a given $G_{KK}$ mass.

Muon correction to the large-$R$ jet four-momenta is applied. $b$-hadrons decay to a muon and a muon neutrino through a $W$ boson with 20% probability. The energy carried by the muon is not
Figure 5.7: Kinematics of 1 TeV $G_{KK}$ MC before (blue) and after (red) muon-in-jet corrections. The reconstructed Higgs masses (top row, left for leading large-$R$ jet, right for subleading large-$R$ jet) are closer to 125 GeV after the correction, which improves the signal efficiency for the signal region selection by $\sim$10% (bottom row, left for $m_{jj}$, right for event distribution differences on the leading-subleading large-$R$ jet mass plane.).
to the calorimeter mass portion of the combined mass, because the track mass calculation already contains the muon track. The muon-in-jet correction improves the overall large-\(R\) jet mass resolution by approximately 5\%, and Figure 5.7 shows the impact of this correction on the 1TeV \(G_{KK}^*\).

Finally, the Higgs candidates (large-\(R\) jets) are also required to have \(|\Delta \eta| = |\eta_{\text{lead}} - \eta_{\text{subj}}| < 1.7\). This is because the spin 2 \(G_{KK}^*\) production is mostly \(s\)-channel with a more central distribution in \(\eta\), while the multi-jet events have larger \(t\)-channel or \(u\)-channel productions with a more forward distribution. Figure 5.8 shows the \(\Delta \eta_{JJ}\) distribution for signal MC and data in inclusive \(b\)-tag channels. This cut is not entirely optimal for scalar signals due to the different spin, but it is fixed for both \(G_{KK}^*\) and scalar selections.

5.4 Resolved Veto

Sometimes one event can be reconstructed in both the resolved method as four small-$R$ jets and the boosted method as two large-$R$ jets with track jets. Figure 5.9 shows an example event display of collision data recorded in 2015.

![Event display of the same event in 2015 data using resolved and boosted topologies.](image)

**Figure 5.9:** Event display of the same event in 2015 data using resolved and boosted topologies. The resolved reconstruction gives a $m_{4J}$ of 873 GeV, and the boosted reconstruction gives $m_{2J}$ of 852 GeV.

In order to avoid events being reconstructed by both the resolved and the boosted analysis, events that pass the resolved signal region selections are vetoed in the boosted analysis. This is an ATLAS political decision, and the effect of vetoing boosted event selection in the resolved analysis was never tested. The gain is a full statistical combination of the resolved and boosted result. This veto reduces the boosted analysis sensitivity in the resonant mass region up to 1.5 TeV, which is recovered in the statistical combination with the resolved analysis. Hence, it is necessary to introduce the resolved selection.22
For the resolved analysis, the four small-\(R\) jets with the highest \(b\)-tagging score are paired to construct two Higgs boson candidates. Each jet must have \(p_T > 40\) GeV , \(|\eta| < 2.5\), \(\text{MV2c10} > 0.8244\) (small-\(R\) jet 70\% \(b\)-tagging working point). Pairings of jets are only accepted as Higgs candidates if they satisfy the following requirements, where \(m_{4j}\) is expressed in GeV:

if \(m_{4j} < 1250\) GeV:

\[
\frac{360 \text{ GeV}}{m_{4j}} - 0.5 < \Delta R_{jj}^{\text{lead}} < \frac{653 \text{ GeV}}{m_{4j}} + 0.475; \quad \frac{235 \text{ GeV}}{m_{4j}} < \Delta R_{jj}^{\text{subl}} < \frac{875 \text{ GeV}}{m_{4j}} + 0.35 \tag{5.1}
\]

if \(m_{4j} > 1250\) GeV:

\[
0 < \Delta R_{jj}^{\text{lead}} < 1; \quad 0 < \Delta R_{jj}^{\text{subl}} < 1 \tag{5.2}
\]

In these expressions, \(\Delta R_{jj,\text{lead}}\) is the angular distance between jets in the leading Higgs boson candidate and \(\Delta R_{jj,\text{subl}}\) for the sub-leading candidate. The leading Higgs boson candidate is defined to be the candidate with the highest scalar sum of jet \(p_T\). This \(\Delta R\) requirement efficiently rejects jet-pairings where one of the \(b\)-tagged jets did not originate from a Higgs boson decay.

Also, mass-dependent requirements are made on the leading Higgs boson candidate \(p_T\) and the sub-leading Higgs boson \(p_T\):

\[
p_T^{\text{lead}} > 0.5 m_{4j} - 105 \text{ GeV}, \quad p_T^{\text{subl}} > 0.33 m_{4j} - 75 \text{ GeV} \tag{5.3}
\]

where \(m_{4j}\) is again expressed in GeV.

A further \((m_{4j}\)-independent) requirement is placed on the pseudorapidity difference between the two Higgs boson candidates, \(|\Delta \eta_{hh}| < 1.5\), which rejects multi-jet events.

\[
|\Delta \eta_{hh}| < 1.1 \text{ if } m_{4j} < 850 \text{ GeV}, \quad |\Delta \eta_{hh}| < 2 \times 10^{-3} m_{4j} - 0.6 \text{ if } m_{4j} > 850 \text{ GeV} \tag{5.4}
\]
Events that have multiple Higgs boson candidates satisfying these requirements (which happens often when \( m_{4j} < 500 \text{ GeV} \)) necessitate an algorithm to choose the correct pairs. The optimal choice would be the combination most consistent with the decays of two Higgs bosons of equal mass. To account for energy loss in measurement and reconstruction resolution, the requirement of equal masses is modified. The distance, \( D_{hh} \), of the leading and subleading Higgs boson candidate masses, \( \left( m_{2j}^{\text{lead}}, m_{2j}^{\text{subl}} \right) \) from the line connecting \((0 \text{ GeV}, 0 \text{ GeV})\) and \((120 \text{ GeV}, 110 \text{ GeV})\) is computed, and the pairing with the smallest value of \( D_{hh} \) is chosen. The values of 120 GeV and 110 GeV are chosen because they correspond to the median values of the narrowest large-\(R\) jet mass intervals that contain 90\% of the signal in simulations. \( D_{hh} \) can be expressed as follows:

\[
D_{hh} = \frac{m_{2j}^{\text{lead}} - \frac{120}{110} m_{2j}^{\text{subl}}}{\sqrt{1 + \left( \frac{110}{120} \right)^2}}.
\]

(5.5)

A requirement on the Higgs boson candidate mass is used to define the resolved signal region:

\[
X_{hh-\text{resolved}} = \left( \frac{m_{2j}^{\text{lead}} - 120 \text{ GeV}}{0.1 m_{2j}^{\text{lead}}} \right)^2 + \left( \frac{m_{2j}^{\text{subl}} - 110 \text{ GeV}}{0.1 m_{2j}^{\text{subl}}} \right)^2 < 1.6,
\]

(5.6)

where the \(0.1 m_{2j}\) terms represent the widths of the leading and sub-leading Higgs boson candidate mass distributions, derived from simulation. In summary, any event is rejected in the boosted selection if the \( D_{hh} \) minimized Higgs candidate passes the resolved signal region \( X_{hh-\text{resolved}} \) cut.

### 5.5 2D Higgs Mass Cut

To separate di-Higgs decays from background productions like QCD multi-jets and top, requirements on the leading and subleading large-\(R\) jet masses are imposed. Figure 5.10 shows the \( G_{kk}^* \) MC \( m_{2j}^{\text{lead}} - m_{2j}^{\text{subl}} \) 2D distribution. The signal is centered around the Higgs boson mass 125 GeV in the 2D plane.
Figure 5.10: For RSG $c = 1.0$ samples, the number of events as a function of leading Higgs candidate mass and subleading Higgs candidate mass, for 1.2 TeV (left) signal and 2 TeV (right) signal samples. The red dotted line in the center correspond to the signal region, passing $X_{hh} < 1.6$.

The signal region is defined using the expression 5.7:

$$X_{hh} = \sqrt{\left( \frac{m_{\text{lead}} - 124 \text{ GeV}}{0.1\, (m_{\text{lead}})} \right)^2 + \left( \frac{m_{\text{subl}} - 115 \text{ GeV}}{0.1\, (m_{\text{subl}})} \right)^2}$$  \hspace{1cm} (5.7)

The denominator of each term in $X_{hh}$ represents the resolution of the reconstructed leading and subleading jet masses. Hence $X_{hh}$ can be interpreted as a $\chi^2$ compatibility with the di-Higgs hypothesis. The subleading large-$R$ jet typically has a biased downward reconstructed mass. Because it is the subleading jet and hence has lower boost. The jet decay constituents are sometimes outside of the jet cone. The energy losses from neutrinos in leptonic $b$ decays and cracks in the calorimeter also contribute. The subleading jet mass center value of $115 \text{GeV}$ accounts for the larger energy loss in subleading jets. The signal region requires $X_{hh} < 1.6$. This cut keeps $\sim 40\%$ of signal events passing all selections. A more optimal signal region definition, using asymmetric signal jet mass resolution and a momentum dependent cut accounting for the higher mass resolution of large $p_T$ jets, can improve the overall search sensitivity by $\sim 8\%$. Since the gain in sensitivity is small, the signal region
is kept to be consistent with the $X_{hh}$-resolved.

5.6 Number of $b$-tagged track jet requirements

In addition to requirements for basic object selection and the $X_{hh}$ cut, the signal regions are defined by further requiring multiple $b$-tags which are consistent with the di-Higgs decay. The MC events passing all signal region selections are sorted into different $b$-tagging categories. This is shown in Figure 5.11.

$X \to hh \to bbb\bar{b}$ results in four $b$-quarks, which ideally leads to four track jets passing $b$-tagging requirements. This is defined as the $4b$ channel. The $4b$ requirement has an overall efficiency of roughly $\varepsilon^4$, where $\varepsilon$ is the $b$-tagging efficiency chosen to be 70%. This means an overall $0.7^4 \sim 0.24$ probability, but having one actual $b$-jet failing $b$-tagging while the other three passing has probability $3 \times 0.7^3 \times (1 - 0.7) \sim 0.31$. Therefore, a $3b$ selection is also introduced to recover the signal efficiency.
An event with $3b$-tags must have at least $3b$-tagged track jets, but can have any number of additional un-tagged track jets. In $4b$ and $3b$, each Higgs candidate can have at most two $b$-tagged track jets, hence $\geq 3b$-tagged track jets cannot be in the same large-$R$ jet.

At the highest resonance mass, the Lorentz boost of the Higgs boson can be large enough to col-limate the $b$-quarks, resulting in $\Delta R_{bb} < 0.2$. The two $b$-quarks decay products are therefore contained inside only one $R = 0.2$ track jet instead of two. This decreases the selection efficiency in $4b$ and $3b$ channels. A third signal channel is added to account for this, denoted by two-tag-split or simply $2bs$. It requires that exactly one $b$-tagged track jet is found in each Higgs candidate, plus an arbitrary number of track jets that must fail the $b$-tag. For masses above 2.5 TeV, the $2bs$ channel (where each large-$R$ jet has exactly one $b$-tagged track jet) significantly improves signal acceptance.

$4b$, $3b$, and $2bs$ channels are chosen as three signal channels, also referred to as $n$-$b$tag channels. The other $b$-tagging channels, also referred to as lower-$b$tag channels, are also sorted and studied. $2b$ channel is defined as one large-$R$ jet has two $b$-tagged track jets, and the other large-$R$ jet has no $b$-tagged track jet. $1b$ channel is defined as one large-$R$ jet has one and only one $b$-tagged track jets, and the other large-$R$ jet has no $b$-tagged track jet. $0b$ channel is defined as both large-$R$ jets have no $b$-tagged track jet. They all have relatively small signal acceptance.

5.7 Signal efficiency and cutflow

Acceptance means the geometric fiducial volume of the detector. Efficiency refers to the detector effectiveness in finding objects. The signal efficiency as a function of $G_{KK}^*$ resonance mass is shown in Figure 5.12, both for the absolute signal efficiency and for the efficiency relative to the previous cut in the selection. Above a mass of $\sim 1$ TeV, the reconstruction of high momentum large-$R$ jets with small $\Delta y$ is efficient, as shown in the orange-triangle curve. The biggest limitation of the boosted
analysis is $b$-tagging inefficiency for track jets with momentum above 500 GeV, as shown in the pink-circle curve. The second biggest limitation is the large-$R$ jet mass resolution, as shown in the purple-square curve. Across the mass range considered, the signal jet masses requirement ($X_{hh}$) and $b$-tagging requirements are $\mathcal{O}(40\%)$ efficient relative to the previous cuts.

![Efficiency curves](image)

*Figure 5.12*: Selection efficiency (left) and relative efficiency with respect to the previous cut (right) as a function of RSG $c=1.0$ signal resonance mass hypothesis for selection cuts. The relative efficiency is defined from the previous cut, where the order of cuts is given by the legend. PassTrig means the event passes the trigger selection; PassDiJetPt means the event passes the leading and sub-leading jet $p_T$ cuts; PassDiJetEta means the event passes the leading and sub-leading jet $\eta$ cuts; PassDetaHH means the events passes the $|\Delta \eta| < 1.7$ cut; PassBJetSkim means the event contains at least two $b$-tagged track jets, inclusive of 2$b$, 3$b$, 4$b$ configurations; PassSignal means the event passes the signal region cut $X_{hh} < 1.6$.

The selection efficiency at various stages for $G_{KK}^*$ with $c = 1.0$, $G_{KK}^*$ with $c = 2.0$, and Heavy Scalar signal samples of all mass points can be found in Tables 5.3, 5.4 and 5.5. The signal production cross section is monotonically decreasing as a function of signal mass.
Table 5.3: The selection efficiency for $G_{kk} \to bb \to bbbb$ events ($\epsilon = 1.0$) at each stage of the event selection. Uncertainties are the MC statistical uncertainty only.

Background Estimation

6.1 Overview

The invariant mass of the two-Higgs-boson-candidate system, $m_{jj}$, is used as the final discriminant between Higgs boson pair production and SM backgrounds. Multi-jet (QCD) is the dominant background. About 40% of the total QCD events are $gg \rightarrow bbb$, and the rest 60% are $gg \rightarrow ccc$ or $gg \rightarrow q\bar{q}q\bar{q}$ where the quark-jets fake multiple $b$-jets. There are neither accurate nor high-statistics MC samples with three or four $b$-tagged track jets contained in two high-$p_T$ large-$R$ jets. A data-driven method is used for estimating both the yield and kinematic distribution of the QCD events. For $tt$ backgrounds, MC samples are available, which provide $tt$ kinematic distributions. The $tt$ yield is also estimated using the same data-driven method to avoid mis-modeling in the

63
MC. The $Z$+jets background is small, and it is estimated by the $Z$+heavy flavor jets MC. The SM $ZZ \to bbb\bar{b}$ has been estimated to be completely negligible using a MC based analysis. For the three signal channels $4b/3b/2b$, the fraction of expected backgrounds are:

- $4b$: QCD $\sim 95\%$, $t\bar{t} \sim 5\%$, $Z$+jets $< 1\%$.
- $3b$: QCD $\sim 90\%$, $t\bar{t} \sim 10\%$, $Z$+jets $< 1\%$.
- $2b$: QCD $\sim 80\%$, $t\bar{t} \sim 20\%$, $Z$+jets $< 1\%$.

All of the kinematic distributions of the QCD background are estimated from low signal yield data $b$-tag channels. These channels use the signal region selection, with the exception of having a different number of $b$-tagged track jets. The differences in kinematic distributions between the fewer $b$-tagged and $n$-tagged signal channels are corrected by reweighting the fewer $b$-tagged samples.

The fewer $b$-tagged channels estimate the shapes of the expected background, but do not estimate the total yield. The sideband region (SB), with the same number of $b$-tags as the signal regions but a cut on $m_{\text{lead}}-m_{\text{subl}}$ different from the $X_{bb}$ cut, is used to estimate the yield. A third region, called the control region (CR), is used to validate the background estimations. The sideband and control regions are optimized to accurately estimate the rate of QCD and $t\bar{t}$ backgrounds.

The definitions of sideband region and control region are introduced in section 6.2. The QCD and $t\bar{t}$ background shape templates are introduced in section 6.3 and section 6.4. The normalization estimation for QCD and $t\bar{t}$ is introduced in section 6.5. The reweighting procedure is explained in section 6.6. The sideband region and control region distributions are shown in section 6.7 and section 6.8. The signal region prediction rescaling and smoothing are discussed in section 6.9. The yields are listed section 6.10.
6.2 Definition of the sideband and control regions

A circular variable \( R_{hh} \) is defined in the 2D \( m_{J}^{\text{lead}}-m_{J}^{\text{subl}} \) mass plane. It has the same central values as \( X_{hh} \), but without resolution terms in the denominators:

\[
R_{hh} = \sqrt{(m_{J}^{\text{lead}} - 12.4 \text{ GeV})^2 + (m_{J}^{\text{subl}} - 115 \text{ GeV})^2}
\]  

(6.1)

Similarly, \( R_{hh}^{\text{high}} \), the circular region with the previous central values shifted up by 10 GeV, is defined as:

\[
R_{hh}^{\text{high}} = \sqrt{(m_{J}^{\text{lead}} - 13.4 \text{ GeV})^2 + (m_{J}^{\text{subl}} - 125 \text{ GeV})^2}
\]  

(6.2)

The definitions of the sideband region, control region, and signal region in the 2D \( m_{J}^{\text{lead}}-m_{J}^{\text{subl}} \) plane are listed in Table 6.1. These regions are shown in Figure 6.1. This Figure also shows that the QCD background rate is decreasing from the low \( m_{J}^{\text{lead}}-m_{J}^{\text{subl}} \) mass region to high \( m_{J}^{\text{lead}}-m_{J}^{\text{subl}} \) mass region in the 2D plane. The \( \bar{t}t \) events are also distinguishable as the vertical cyan band where \( m_{J}^{\text{lead}} \sim 173 \text{ GeV} \).

<table>
<thead>
<tr>
<th>Region</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>signal region (SR)</td>
<td>( X_{hh} &lt; 1.6 )</td>

<tr>
<td>sideband region (SB)</td>
<td>( 33 \text{ GeV} &lt; R_{hh} ) and ( R_{hh}^{\text{high}} &lt; 58 \text{ GeV} )</td>
</tr>
</tbody>
</table>

The control region is as close to the signal region as possible. The ring shape around the SR allows a good test for the background predictions with different \( m_{J}^{\text{lead}}-m_{J}^{\text{subl}} \) combinations, and avoids too few or too many \( \bar{t}t \) events. The current control region gives \( N_{CR} \sim 2N_{SR} \), which contains good statistics and does not affect the sideband region design.
The sideband region must be a reasonable approximation for the QCD events contained in the control region and signal region. It is therefore chosen as the ring outside the control region. The shift upwards in the center of $R_{bb}^{high}$ helps to contain more $\tilde{t}\tilde{t}$ events in the normalization estimates. A larger SB will potentially increase the kinematic differences between different QCD processes in CR/SR and SB. Different $m_{\text{lead}}^{J}$-$m_{\text{subl}}^{J}$ reflects of different fractions of $g \to b\bar{b}$ and $g \to c\bar{c}/q\bar{q}$ events. This kinematic bias should be reduced as much as possible. However, a smaller SB will introduce larger statistical uncertainties in the normalization estimation. This is a bias-variance trade off. The current design gives roughly $N_{SB} \sim 4N_{SR}$ and $N_{SB} \sim 2N_{CR}$, which provides a good balance between the bias and variance in the background estimation.

Figure 6.1: The $m_{\text{lead}}^{J}$ vs $m_{\text{subl}}^{J}$ distribution of data in $b\bar{b}$ region. The signal region is the area surrounded by the inner (red) dashed contour line, centered on $(m_{\text{lead}}^{J}=124 \text{ GeV}, m_{\text{subl}}^{J}=115 \text{ GeV})$. The control region is the area between the signal region and the intermediate (orange) contour line. The sideband region is the area between the control region and the outer (yellow) contour line.
The fraction between the expected events in different $m_{j\text{lead}}-m_{j\text{subl}}$ regions and the total number of events as a function of $G_{KK}^*$ resonance mass is shown in Figure 6.2. For the 4$b$, 3$b$, and 2$b$ channels, there is no significant signal contamination in the control and sideband regions.

**Figure 6.2:** Detailed signal efficiency in different signal/control/sideband regions in $n$-tagged channels and the inclusive $b$-tagged channel, which includes 2$b$, 1$b$, and 0$b$ as well, (bottom right) as a function of $G_{KK}^*$ resonance mass for selection cuts. The efficiencies are relative to the total number of events in the preselection.
Table 6.2: Definitions of the QCD background estimation sample for $4b/3b/2bs$. $n_{b}^{\text{lead/subj}}$ stands for the number of $b$-tagged track jets in the leading/subleading large-$R$ jet.

6.3 **QCD Multi-Jet**

The QCD multi-jet background prediction relies on finding $b$-tagged channels that have events similar to signal channel event properties. These channels are defined to be identical to the signal channels except with a lower required number of $b$-tagged track jets associated with the large-$R$ jets. They are orthogonal to the $n$-tagged channels with no overlapping events, as listed in Table 6.2. They are assumed to be all background, and the signal yield in these channels are negligible, as shown in Figure 5.11a. Detailed selection requirements and details are listed:

- For the $2bs$ category, $1b$ data events, where one large-$R$ jet has one and only one $b$-tagged track jets, and the other large-$R$ jet has no $b$-tagged track jet, is used for modeling.

- For the $3b$ and $4b$ categories, $2b$ data events, where one large-$R$ jet has two $b$-tagged track jets, and the other large-$R$ jet has no $b$-tagged track jet, is used for modeling. The $2b$ sample is further split into $80\% - 20\%$ parts, where each is used separately for $3b$ and $4b$ background estimations. This ensures the shape estimations of $3b$ and $4b$ QCD estimates are uncorrelated.

The $2b$ and $2bs$ channels are orthogonal channels without any overlapping events. The $1b$-tagged channel also requires that both large-$R$ jets are associated with at least one track jet. Similarly, the $2b$-tagged channel requires that one large-$R$ jet has at least one track jet and the other one has at least two track jets. Specifically for the $4b$ background modeling, each large-$R$ jet must have at least two track jets. This prevents biases in the $m_{4J}$ distribution from the number of associated track jets.
The MC predicted $t\bar{t}$ and $Z$+jets events in the $tb/2b$ channels are subtracted from the data distributions to produce the QCD estimation. Therefore, the number of QCD events, $N_{\text{qcd}}$, is estimated in Equation 6.3.

$$N_{\text{qcd}} = N_{\text{data}} - N_{t\bar{t}} - N_{Z+jets} \quad (6.3)$$

The resolved veto imposed impacts the $4b$ background estimation. To account for this effect, the 20\% $2b$ data events used for $4b$ background estimation are excluded. The excluded events must have at least two small-$R$ jets that are $b$-tagged (passing the resolved 70\% $b$-tagging working point), and in the case where the two other non-$b$-tagged resolved jets can make a Higgs candidate, events must also pass the $X_{bb-\text{resolved}} < 1.6$ cut. This ensures that a similar sculpting effect from the resolved veto is reflected in the background estimation in the $4b$ signal region. This reduces the estimated number of events in the signal region by 10\%.

Given the $1b/2b$ QCD background samples, the normalization estimation of the $4b/3b/2bs$ QCD background is determined in the sideband by fitting the $m_{\text{lead}}$ distribution simultaneously with QCD and $t\bar{t}$ background templates, as described in section 6.5. There are kinematic differences between the $1b/2b$ channels and the $4b/3b/2bs$ channels. A kinematic reweighting is applied to correct for such differences, as described in Section 6.6.

6.4 $t\bar{t}$

The $t\bar{t}$ events in the signal region decay to $bW^+/\bar{b}W^-$ and the $W$ further decays into two quarks. The leptonically decaying $W$s are rare due to the large-$R$ jet $p_T$ cut. The $t\bar{t}$ MC is first scaled by the total luminosity times the cross-section. The boosted event selections are then applied. The estimated $t\bar{t}$ kinematic distributions come from MC simulations.

To account for possible mis-modeling
in the MC, a normalization scaling factor is derived from a fit to data in the sideband region, as described in section 6.5.

For $4b$ and $3b$ signal regions, there are not sufficient $t\bar{t}$ MC statistics for high $m_{3J}$. Instead, the $2bs$ $t\bar{t}$ MC shapes are used. It is rescaled to the $4b$ and $3b$ $t\bar{t}$ MC yields. This reduces the statistical uncertainties for $4b$ and $3b$ $t\bar{t}$ at high $m_{3J}$. A comparison between the $4b/3b/2bs$ shapes for the $m_{3J}$ distributions in the signal regions is shown in Figure 6.3. The shapes are compatible, with the $4b$ having much larger statistical uncertainties. Differences between these distributions will be used as a systematic, as described in chapter 7. Since the same $t\bar{t}$ distribution is used for the $4b/3b/2bs$ SR predictions, the $t\bar{t}$ shape systematics are considered correlated in the final results.

![Figure 6.3: Normalized 2bs, 3b, and 4b $t\bar{t}$ MC $m_{3J}$ (mHH) distribution in the signal region. The uncertainties are statistical.](image)

(a) Linear scale

(b) Log scale
6.5 Fitting procedure for QCD and \( t\bar{t} \) normalization

The number of \( 4b/3b/2b \) background events in a given region \( R \) (SB / CR / SR) is shown in Equations 6.4, 6.5 and 6.6:

\[
\begin{align*}
N_{bkg}^{4b-R} &= \mu_{4b}^{qcd} N_{qcd}^{4b-R} + \alpha_{4b}^{t} N_{Z+jets}^{4b-R};
\mu_{4b}^{qcd} \sim \frac{\Lambda_{4b-SB}^{qcd}}{\Lambda_{4b-SB}^{qcd}} \quad (6.4) \\
N_{bkg}^{3b-R} &= \mu_{3b}^{qcd} N_{qcd}^{3b-R} + \alpha_{3b}^{t} N_{Z+jets}^{3b-R};
\mu_{3b}^{qcd} \sim \frac{\Lambda_{3b-SB}^{qcd}}{\Lambda_{3b-SB}^{qcd}} \quad (6.5) \\
N_{bkg}^{2b-R} &= \mu_{2b}^{qcd} N_{qcd}^{2b-R} + \alpha_{2b}^{t} N_{Z+jets}^{2b-R};
\mu_{2b}^{qcd} \sim \frac{\Lambda_{2b-SB}^{qcd}}{\Lambda_{2b-SB}^{qcd}} \quad (6.6)
\end{align*}
\]

\( \mu_{qcd} \) is essentially an extrapolation factor to account of the fewer number of events passing the higher number of \( b \)-tagged track jet selection. \( \mu_{qcd} \) is roughly a constant over SB/CR/SR \( m_{J}^{lead} \) regions. Validation of this assumption can be found in Appendix D. \( \alpha_{tt} \) is a scale factor, correcting the \( t\bar{t} \) MC yield. \( \mu_{qcd} \) and \( \alpha_{tt} \) are derived in the sideband region. They are used as multiplicative constants in other regions of the mass plane (i.e. the control region or the signal region).

A binned maximum likelihood fit is used to find the values of \( \mu_{qcd} \) and \( \alpha_{tt} \), as well as the correlation between them. These scaling parameters are determined independently using the same procedure in the \( 4b/3b/2b \) sideband regions. Due to the \( p_{T} > 450 \text{ GeV} \) cut imposed on the leading large-\( R \) jet, the top quark decay products are fully contained inside the leading large-\( R \) jet in \( t\bar{t} \) events. The \( m_{J}^{lead} \) from \( t\bar{t} \) events has a clean peak around \( m_{top} \sim 175 \text{ GeV} \) in the sideband region. It has the best separation between QCD and \( t\bar{t} \) shapes. Therefore, the fit is performed on the \( m_{J}^{lead} \) spectrum in the sideband region.

Figure 6.4 shows the post-fit spectrum of \( m_{J}^{lead} \) in the \( n \)-tagged sideband regions. The \( m_{J}^{lead} \) shapes in data are well modeled by the predicted backgrounds. The sharp turn-on at \( m_{J}^{lead} \sim 75 \text{ GeV} \) and
sharp fall around 180 GeV are due to the sideband region mass cut on $m_{\text{lead}}^j$. The dip in the $m_{\text{lead}}^j$ distribution at $\sim 125$ GeV is because the sideband region doesn’t contain events from the control and signal regions. The fitting errors on $\mu_{\text{qcd}}$ and $\alpha_{t\bar{t}}$ are applied as systematic uncertainties taking into account their correlation.

Figure 6.4: Simultaneous fit of $\mu_{\text{qcd}}$ and $\alpha_{t\bar{t}}$ in $4b$, $3b$ and $2b$ sideband regions using the leading large-$R$ jet mass.

The $t\bar{t}$ MC sample normalization is further corrected from the fitted $\alpha_{t\bar{t}}$. At first, $\alpha_{t\bar{t}}$ is assumed to be 1. Once the first fit is done, the QCD background is re-estimated using the updated $2b\alpha_{t\bar{t}}$ value, which has the smallest uncertainty. Then, the fit is repeated until the change in $\alpha_{t\bar{t}}$ is less than 0.01. This iterative procedure helps correct the $\alpha_{t\bar{t}}$ bias in the data-driven QCD template.
The values of $\mu_{\text{qcd}}$ and $\alpha_{\text{tt}}$ estimated by the fits in the $4b/3b/2bs$ sideband regions can be found in Table 6.3, along with the correlation $\xi(\mu_{\text{qcd}}, \alpha_{\text{tt}}) = \frac{\text{Cov}(\mu_{\text{qcd}}, \alpha_{\text{tt}})}{\sigma_{\mu_{\text{qcd}}} \sigma_{\alpha_{\text{tt}}}}$. $\mu_{\text{qcd}}$ and $\alpha_{\text{tt}}$ are approximately 70% negatively correlated, due to the nature of the two components fit and the fixed normalization. This negative correlation leads to a smaller total normalization uncertainty.

### 6.6 QCD REWEIGHTING

Reweighting gives the QCD background sample events weights different from one. This results in a different distribution in all QCD kinematic distributions. The weights are derived from kinematic differences between a Higgs candidate that has $b$-tags and a Higgs candidate that doesn’t have $b$-tags. The reweighting variables are the track jet $p_T$ and large-$R$ jet $p_T$. More supporting plots are shown in Appendix E.

It is important to model the QCD background as well as possible in all regions of the phase space. Using the $1/2b$ channels to model the $2bs/3b/4b$ channels can introduce discrepancies in the modeling of the estimated QCD background versus the data. These discrepancies arise from the non-trivial effect that $b$-tagging requirements can have in sculpting the track jet $p_T$ and $\eta$ distributions.

The reweighting method is motivated by Figure 6.5. In the plots, $ob$, $1b$ and $2bs$ kinematic distributions in data are compared. Except $2bs$ data only contains the sideband region, $ob$ and $1b$ are inclusive of sideband, control, and signal regions. The $1b$ sample is further split into four subcategories
Figure 6.5: Comparison of track jet $p_T$ distributions in different $b$-tag channels. Data are shown in the plots. They contain inclusive SB/CR/SR regions for 0$b$ and 1$b$, and only the SB region for 2$b$. At the bottom of the plots, all the ratios are taken with respect to the 0$b$ tagged distribution.

listed in Table 6.4, depending on which track jet gets $b$ tagged. The figure shows that 2$b$s channel has very similar track jet $p_T$ distributions to the 1$b$ channel with a $b$-tagged track jet. It also shows that in the 1$b$ channel, the track jet $p_T$ distribution in the non $b$-tagged Higgs candidate behaves like the 0$b$ channel track jet $p_T$ distribution.

</table>

This reweighting technique is applied to the 1/2b data only. The reweighting procedure is the same for the 4b, 3b, and 2b channels. The 2b QCD sample is already split into orthogonal parts for 3b and 4b estimations, as described in section 6.3.

For 2bs, the 1b non-$b$-tagged Higgs candidate is reweighted to be like a 1b-tagged Higgs candidate; for 3b, the 2b non-$b$-tagged Higgs candidate is reweighted to be like a 1b-tagged Higgs candidate; for 4b, the 2b non-$b$-tagged Higgs candidate is reweighted to be like a 2b-tagged Higgs candidate. For each category, the events are split into two orthogonal subgroups, based on whether leading/subleading Higgs candidate is $b$-tagged. Each event gets a weight, such that the reweighted untagged Higgs candidate’s distributions agree with the corresponding $b$-tagged Higgs candidate’s.

One natural choice of a reweighting variable is the $p_T$ of the track jets in the event, since the $b$-tagging efficiency and the $b$-tagging fake rate have a strong track jet $p_T$ dependence. Also, large-$R$ jet $p_T$ is reweighted to account for the difference from light/$c$/b quarks composition in QCD events at different energy scales. The three reweighted variables are the leading large-$R$ jet $p_T$, leading large-$R$ jet leading track jet $p_T$, and subleading large-$R$ jet leading track jet $p_T$.

The each reweighting iteration is described below:

- Subtract 1/2b $t\bar{t}$ and $Z$+jets samples in the SB + CR + SR regions from the 1/2b tag data in the SB + CR + SR regions to get the 1/2b QCD inclusive estimate. Weights from all previous iterations, if applicable, are all applied.

75
• Separate the $1/2b$ sample into two parts: (A) has the $b$-tagged Higgs as the leading $p_T$ Higgs candidate, and (B) has the $b$-tagged Higgs as the subleading $p_T$ Higgs candidate.

• For each variable, i.e. the large-$R$ jet $p_T$: normalize sample A to sample B’s total number of events, take the ratio of sample A’s distribution over sample B’s distribution, and fit the ratio with a smooth spline function (TSpline3). The binning of the distribution needs to be carefully chosen such that each bin has enough statistics to calculate a meaningful ratio.

• Use this spline function to extract reweighting values $w_e$ for each variable that is considered. Then, the difference from one is scaled by 0.75 to get a new weight $w$. So $w = (w_e - 1) \times 0.75$. This accounts for over correlation by the spline and accelerates convergence.

• For each event, all the three weights from three variables are multiplied together to get a data event weight. Another constraint is applied, such that each event’s total reweighting value is constrained to be within a 0.05 to 10 range. This avoids over corrections.

Examples for the reweighting procedure are shown in Appendix E. The weights are almost converging to one after three iterations. To ensure all kinematics regions are covered, a total of ten iterations are used to stabilize the reweighting. The reweighting value for each variable is also constrained to be within a $-30\%$ to $+40\%$ range compared to one, to avoid over corrections.

Table 6.5: Background scaling parameters ($\mu_{\text{qcd}}$ and $\alpha_{\text{tt}}$) estimated from fits to the $m_{J^\text{lead}}$ distributions in $4b/3b/2b$ sideband regions post reweighting. $\varphi(\mu_{\text{qcd}}, \alpha_{\text{tt}}) = \frac{\text{Cov}(\mu_{\text{qcd}}, \alpha_{\text{tt}})}{\sigma_{\mu_{\text{qcd}}} \sigma_{\alpha_{\text{tt}}}}$.

</table>

At the end of reweighting, the $\mu_{\text{qcd}}$ and $\alpha_{\text{tt}}$ is re-evaluated. The estimated $\mu_{\text{qcd}}$ and $\alpha_{\text{tt}}$ values before reweighting can be found in Table 6.5. The values are statistically consistent with the values in Table 6.3.
6.7 \( m_{3J} \) IN THE SIDEBAND REGION

Figure 6.6 shows comparisons of the predicted \( m_{3J} \) background distributions to those observed in data in the sideband regions. The predicted background and observed distributions are in agreement, with no significant excess. Other sideband region distributions are shown in Appendix A.

**Figure 6.6:** The \( m_{3J} \) distributions in the sideband region of the boosted analysis for the data and the predicted background for \( 4b \), \( 3b \), and \( 2bs \) channels. The data-to-background ratio (bottom panels) shows the statistical uncertainties as the gray hatched band.
6.8 $m_{3J}$ IN THE CONTROL REGION

Figure 6.7 shows comparisons of the predicted $m_{3J}$ background distributions to those observed in data in the control regions. The predicted background and observed distributions are in good agreement. Other control region distributions are shown in Appendix B.

![Figure 6.7: The $m_{3J}$ distributions in the control region of the boosted analysis for the data and the predicted background for $4b$, $3b$, and $2bs$ channels. The data-to-background ratio (bottom panels) shows the statistical uncertainties as the gray hatched band.](image-url)
6.9 $m_{3J}$ RESCALE AND SMOOTHING IN THE SIGNAL REGION

The $m_{3J}$ resolution is further improved by rescaling. In the signal region, the four-momentum of each large-$R$ jet is multiplied by a factor $m_H/m_J$. From this, a scaled $m_{3J}$ is calculated. This correction improves the jet mass and momentum resolution of each large-$R$ jet for signal events. There is little impact on the background distribution. Using the scaled $m_{3J}$ distribution, the expected exclusion limits are slightly better at low mass and slightly worse at high mass, with differences on the order of 10% from the nominal $m_{3J}$ limits. The scaled $m_{3J}$ distribution can be found in Figure 6.8.

Due to limited $1/2b$ statistics at high $m_{3J}$ above 2500 GeV and the limited $t\bar{t}$ statistics above 1100 GeV, different fits are performed to smooth the $m_{3J}$ mass distributions in the signal regions. This ensures each $m_{3J}$ bin has a non-zero predicted background value. The $4/3/2b$s QCD and $t\bar{t}$ signal region scaled $m_{3J}$ distributions are fitted with the following functional form:

$$y = \frac{a}{(m_{3J}/\sqrt{3})^2} \left( 1 - \frac{m_{3J}}{\sqrt{3}} \right) \left( b - c \log \left( \frac{m_{3J}}{\sqrt{3}} \right) \right)$$

(6.7)
where $\sqrt{s} = 13000$ GeV, the fit range is $1200 < m_{J\ell} < 3000$ GeV, and the three free parameters are $a$, $b$ and $c$. The values of the estimated fit parameters in the $4b$, $3b$, and $2bs$ signal regions can be found in Table 6.6. Figure 6.9, 6.10, and 6.11 show the smoothing fits for the QCD background and the $t\bar{t}$ background in the $4b$, $3b$, and $2bs$ signal regions. The smoothing fit statistical uncertainties are also shown on these two plots. Given that $1/2b$ channels are used for deriving the QCD shape for $4/3/2bs$ signal regions, the slope parameters ($a$) are similar for $4/3/2bs$ QCD backgrounds.

![Figure 6.9](image_url)

**Figure 6.9:** Fits for scaled background smoothing are shown for the $4b$ signal region. The figures show the distributions with the fit central value and the fit variations determined by varying the fit parameters within uncertainties and taking into account parameter correlations.

The final signal region predictions using scaled $m_{J\ell}$distributions, with only statistical uncertainties, are shown in Figures 6.12, 6.13, and 6.14. This includes smoothing statistical uncertainties only. Uncertainties on the fit parameters are propagated as systematic uncertainties, though they are essentially replacing the bin-by-bin statistical uncertainties of the background estimates (which are not used once smoothing is applied). More details on other systematics, including smoothing systematics, shape uncertainties, and other sources of uncertainties are discussed in section G.3.
Figure 6.10: Fits for scaled background smoothing are shown for the $3b$ signal region. The figures show the distributions with the fit central value and the fit variations determined by varying the fit parameters within uncertainties and taking into account parameter correlations.

Figure 6.11: Fits for scaled background smoothing are shown for the $2bs$ signal region. The figures show the distributions with the fit central value and the fit variations determined by varying the fit parameters within uncertainties and taking into account parameter correlations.

6.10 Yields

The event yield results showing the estimated backgrounds, the signal predictions, and the observed data in the $4b$, $3b$, and $2bs$ signal regions, control regions, and sideband regions can be found in Table 6.7, 6.8, and 6.9, respectively. The total background statistical uncertainty is less than the
Table 6.6: Smoothing parameters in $4b, 3b$, and $2bs$ signal regions for scaled mass distributions, the correlation between parameters is almost always 0.99.

Every question has a proper answer. Every soul has a proper place.

7

Systematics

7.1 Overview

This analysis is statistically limited. The largest uncertainties for signal processes are from $b$-tagging efficiency corrections and jet mass resolution. The major background, QCD, is estimated with the data-driven method. Therefore, detector modeling uncertainties have very small impacts on the background estimation. The largest background estimation uncertainty comes from the differences between data and prediction in the control regions. The total uncertainties for the boosted analysis will decrease with higher integrated luminosity in the future.

The signal acceptance is affected by theoretical uncertainties described in section 7.2. These are renormalization and factorization scales uncertainties, PDF uncertainties, and initial state radiation
(ISR) and final state radiation (FSR) uncertainties. The ISR and FSR variations are the largest theoretical uncertainties. The uncertainty on the expected signal yield is typically below 10% but can increase to 23%, depending on the signal mass.

Detector modeling uncertainties are evaluated in section 7.3. They include $b$-tagging efficiencies, jet energy scale (JES), jet energy resolution (JER), and jet mass resolution (JMR). These uncertainties can change both the shape and normalization of the signal and $t\bar{t}$ distributions.

A statistical uncertainty on the value of $\mu_{\text{qcd}}$ and $\alpha_s$ for the $4b$, $3b$, and $2bs$ signal regions is determined from the fitting procedure described in section 6.5. Two uncertainties are calculated from the covariance matrix of the normalization fit, which are then applied to the background predictions. Correlations between $\alpha_s$ and $\mu_{\text{qcd}}$ are fully retained.

The background modeling uncertainties are derived from the difference between data and prediction in the control regions. Both the normalization and shape uncertainties in $m_{\text{tJ}}$ are considered, as discussed in sections 7.4 and 7.5. The size and shape of sideband and control regions are varied to ensure the uncertainty estimations are robust.

The total uncertainties are summarized in section 7.6. A validation of these uncertainty estimations are shown in Appendix F. Additional uncertainties will be discussed in the Appendix G. They include the $t\bar{t}$ theoretical uncertainties, the shape uncertainty of the $t\bar{t}$ prediction in the $3/4b$ signal regions, and the uncertainty from the smoothing function fit range and functional form.

7.2 Theoretical uncertainties

The theoretical uncertainties on the acceptance times efficiency ($A \times \varepsilon$) are evaluated by analysis of specially-generated, particle-level signal samples. The generation of these samples follows the
configuration of the baseline samples, but with modifications to probe the following theoretical uncertainties: uncertainties in the parton density functions, uncertainties due to missing higher order terms in the matrix elements, and uncertainties in the modeling of the underlying event (including multi-parton interactions), of hadronic showers, and of initial and final state radiation.

To evaluate the potential effect of missing higher order terms in the matrix element, the renormalization and factorization scales used in the signal generation are varied by both 0.5 and 2 for the signals. The largest difference in signal yield from the default scales is taken as the uncertainty.

Uncertainties due to modeling of the parton shower and the underlying event are evaluated by varying the MC generator listed in section 4.2.1. For the $G_{kk}$ samples, Pythia8 is switched to Herwig++, while for the scalar and non-resonant signals Herwig++ is switched to Pythia8.

PDF uncertainties are evaluated using the PDF4LHC15_nlo_mc set, which combines CT14, MMHT14 and NNPDF3.0 PDF sets. The uncertainty is evaluated by calculating the acceptance for each PDF set. The standard deviation of these acceptance values is taken as the PDF uncertainty. The uncertainty in acceptance due to PDF is less than ±1% across the full mass range considered for the analysis.

The theoretical uncertainties are implemented in the final statistical analysis as normalization uncertainties on the signals, with the value taken from a polynomial fit of the cross section and the mass of the signal. This fit smooths out statistical fluctuations and allows interpolation between the generated signal masses.
7.3 Detector and reconstruction uncertainties

7.3.1 Luminosity uncertainty

The uncertainty in the integrated luminosity of the combined 2015 and 2016 datasets is $36.1 fb^{-1} \pm 2.1%$\(^{74}\). This uncertainty is applicable to the backgrounds with normalizations determined from simulation, and further propagated to the QCD prediction through the data-driven background estimation procedure. This uncertainty is also applied to the signal normalization prediction. It has a small impact on this analysis.

7.3.2 Large-\(R\) jet resolution and scale uncertainties

There are uncertainties on the large-\(R\) jets energy scale (JES) and energy resolution (JER), as well as the mass scale (JMS) and mass resolution (JMR). The uncertainties on the JES and JMS are derived in situ from 13 TeV \(pp\) collisions using techniques described in Ref.\(^{75}\). Discrepancies in jet four-momenta observed between data and MC are assigned as uncertainties on the energy/mass scales of the jet.

The uncertainties on the jet mass resolutions are estimated by applying a Gaussian smearing. For each signal mass point, the large-\(R\) trimmed jet mass is smeared such that the intrinsic resolution is increased by 20%. For jet energy resolution, the large-\(R\) jet’s momentum is smeared with an absolute 2% uncertainty. The nominal MC mass resolution \(\sigma_M\) for every signal mass is determined by fitting the \(M_{\text{jet}}/M_{\text{truth}}\) distribution before the final \(X_{hh}\) cut with a Gaussian function.

7.3.3 \(b\)-tagging uncertainties

Calibrations, or correction factors per \(p_T\) bin, for the \(b\)-tagging efficiency of \(R = 0.2\) track jets have been derived using \(\bar{t}t\) events in data and simulation, as described in Ref\(^{74,76,77}\). The calibrations
are applied to the signal and $t\bar{t}$ simulations, for better data and simulation agreement. The calibrations also include uncertainties which modify the $b$-tagging efficiency and thus modify the signal or $t\bar{t}$ acceptances. For $b$-jets with $p_T > 300$ GeV, systematic uncertainties in tagging calibrations are extrapolated with simulations and are consequently larger. These calibration uncertainties are propagated through the full selections. The $b$-tagging uncertainty changes the signal yield by $30\%$ and the $t\bar{t}$ yield by $12\%$, depending on the $b$-tagging channel.

A significant reduction of $b$-tagging systematic uncertainty for resonant signals in the $3b$ channel is observed. This is because in the $3b$ channel, there may exist one not $b$-tagged jet, or anti-$b$-tagged jet. When a $b$-tagged jet is calibrated with a scale factor $w_f$ with uncertainties $\Delta w_f$, any change in $b$-tagging efficiency must be corrected in the opposite direction for the anti-$b$-tagged jets in order to ensure that the total number of events is fixed. The anti-$b$-tagging calibration scale factor is defined in Equation 7.1:

$$
\Delta w_{sf}^{anti} = \frac{(1 - \Delta w_f \epsilon_b)}{(1 - \epsilon_b)}
$$

where $\epsilon_b$ is the tagging efficiency. In the $4b$ channel, $(\Delta w_f)^4$ is applied on the MC event weight as the uncertainty. In the $3b$ channel, $(\Delta w_f)^3 \Delta w_{sf}^{anti}$ is the uncertainty. This anti-correlation reduces the $b$-tagging uncertainty on the $3b$ signal region. In the $2bs$ channel, $(\Delta w_f)^2 (\Delta w_{sf}^{anti})^2$ is the uncertainty. This makes the $b$-tagging uncertainty larger in the $2bs$ channel than the $3b$ channel.

This feature is justified in Figure 7.1. One variation of $b$-tagging scale factor is tested on $G_{K\bar{K}}$ simulations. In the $4b$ plot, no $\Delta w_{sf}^{anti}$ is applied. The variation on the signal yield is only due to $\Delta w_f$. In the $3b$ plot, $\Delta w_{sf}^{anti}$ is applied. This $w_{sf}^{anti}$ reduces the variation from $\Delta w_f$. In the $2bs$ plot, $(\Delta w_{sf}^{anti})^2$ is applied. This $w_{sf}^{anti}$ further reduces the variation from $\Delta w_f$, causing the signal yield difference increase in comparison with the $3b$ case.
Figure 7.1: Impact on $m_{J}$ of the efficiency scale factor $w_{sf}$ and inefficiency scale factor $w_{anti sf}$. The MC is 2 TeV $G_{KK}$ with $c = 1.0$.

7.4 Background normalization uncertainties

$\mu_{qcd}$ estimation is dependent on the choices of sideband region and control region. Additional sideband and control regions were designed and tested. They are further illustrated in Appendix H.
and are listed below:

- Low-mass control region: the center position of the circle that defines nominal control region is moved down by 3 GeV in both leading and sub-leading large-jet mass.

- High-mass CR: the center position of the circle that defines nominal control region is moved up by 3 GeV in both leading and sub-leading large-R jet mass.

- Signal-depletion control region (Small CR): the $X_{hh}$ cut that defines signal region is increased to 2.0 from 1.6. This variation only affect the control region, while the signal region remains unchanged (i.e. the signal region is still defined by $X_{hh} < 1.6$, while the control region is defined with $X_{hh} > 2.0$ and $R_{hh} < 33$ GeV).

- High-mass sideband region: The signal region and control region remain unchanged, and the center position of the circle that defines nominal SB is moved up by 3 GeV in both the leading and sub-leading large-R jet mass.

- Low-mass sideband region: The signal region and control region remain unchanged, and the center position of the circle that defines nominal SB is moved up by 3 GeV in both the leading and sub-leading large-R jet mass.

- Large sideband region: The signal region and control region remain unchanged, and the sideband region is redefined as $33 \text{ GeV} < R_{hh}$ and $R_{hh}^{\text{high}} < 61$ GeV.

- Small sideband region: The signal region and control region remain unchanged, and the sideband region is redefined as $33 \text{ GeV} < R_{hh}$ and $R_{hh}^{\text{high}} < 55$ GeV.

These variations are tested after the full reweighting procedure as described in section 6.6. The differences between prediction and observed data are summarized in Tables 7.1, 7.2, and 7.3. Based on these differences, the largest differences between the predicted backgrounds and observed data is taken as the uncertainty. A final 2.9% normalization uncertainty is assigned to the $2b$ signal region, 4.3% to the $3b$ signal region, and a 12.2% normalization uncertainty is assigned to the $4b$ signal region.

7.5 Background \(m_{3J}\) shape uncertainties

As shown in Figure 6.7, the \(m_{3J}\) shape of the predicted background is in good agreement with the \(4b, 3b,\) and \(2bs\) data in the control region. The differences in \(m_{3J}\) distributions in the control region
are evaluated and used to assign background $m_{3\ell}$ estimation uncertainties in the signal region. First, the predicted and the data distributions in the control region are smoothed. The smoothing fits and the ratios are shown in Figures 7.2, 7.3, and 7.4. The ratio between the smoothed background $m_{3\ell}$ predictions and the smoothed $4b/3b/2bs$ data $m_{3\ell}$ distributions is taken as the shape systematic uncertainty. This is the black line in Figures 7.2b, 7.3b, and 7.4b. This systematic uncertainty is further split into two parts: $m_{3\ell} < 2000$ GeV and $m_{3\ell} > 2000$ GeV. This ensures the low and high mass region post-fit pulls can vary independently. The QCD background prediction in the signal region is scaled with this ratio while maintaining the same normalization. The same shape uncertainty is applied for both the $m_{3\ell}$ and the scaled $m_{3\ell}$ distribution.

![Figure 7.2: $m_{3\ell}$ smoothing fit and ratio in the $4b$ control region. The uncertainty bands contain the smoothing function parameter variations.](image)

### 7.6 Summary of systematics

Tables 7.4, 7.5, and 7.6 show the percent impact of systematics used in the boosted analysis on the predicted signal and background yields in the $4b$, $3b$, and $2bs$ signal region. The shape systematics that have no impact on the yield are not listed. The “Bkg Est” row contains both the background modeling uncertainties and background normalization fit uncertainties.
The fractional size of systematics on MC as a function of the $G_{KK}$ mass can be found in Figure 7.5. The largest uncertainty in the $4b$ and $2b$ channels comes from $b$-tagging, followed by the JMR uncertainty. In the $3b$ channel, although $b$-tagging systematics is still one of the largest uncertainty categories, it is much smaller than in the $4b$ channel, as discussed in Section 7.3.3.
Figure 7.5: Impact of each systematic on MC signal region prediction as a function of the $G_{\kappa \kappa}$ mass.
Table 7.4: Percent impact of the dominant systematics on the background acceptance and on the signal acceptance of $G_{kk}$ with $\epsilon = 1.0$ in the $4b$ channel signal region.

Result

The signal regions in data were blinded to reduce the bias in selection optimization. After approval within the ATLAS analysis group, the signal regions were unblinded in July 2017. The unblinded boosted signal region results are shown in section 8.1. The resolved signal region results are shown in section 8.2. The boosted analysis observed limits for $G_{KK}^*$ and scalar $H$ are shown in section 8.3. The combined boosted and resolved limits are shown in section 8.4.

8.1 Boosted signal region

The unblinded signal region yields are summarized in Table 8.1. The $4b/3b/2bs$ channel unscaled $m_{dij}$ distributions are shown in Figures 8.1, 8.2, and 8.3. No significant excess in the number of ob-
served events or in the dijet mass distributions is observed. The 4b/3b/2bs channel scaled $m_{3J}$ distributions are shown in Figures 8.4, 8.5, and 8.6. Again, no significant excess in the scaled $m_{3J}$ distributions is observed. No events are observed with $m_{3J}$ or scaled $m_{3J}$ above 4 TeV. The other kinematic distributions in the signal region are shown in Appendix C.

Table 8.1: Unblinded signal region predictions and results. All systematic uncertainties are included for backgrounds. The Poisson uncertainty in data is shown for comparison.

Figure 8.1: Unscaled $m_{3J}$ distributions in the 4b signal region after unblinding.
8.2 Resolved signal region

The number of events observed in the data, the predicted number of background events in the signal region, and the predicted yield for three potential signals are presented in Table 8.2 for both
Figure 8.4: Scaled $m_{3J}$ distributions in the $4\ell$ signal region after unblinding.

Figure 8.5: Scaled $m_{3J}$ distributions in the $3\ell$ signal region after unblinding.

the 2015 and 2016 datasets. The numbers of observed and predicted events in the control region are also shown. A discrepancy between data and the total prediction is seen in the 2016 dataset; about
Figure 8.6: Scaled $m_{3j}$ distributions in the $2\ell b$ signal region after unblinding.

Half of this excess can be attributed to one bin at $m_{4j} = 280$ GeV. This could be a trigger turn-on effect.

Table 8.2: The number of predicted background events in the signal region for the resolved analysis compared to the data, for the 2015 and 2016 datasets. The yields for three potential signals, an $800$ GeV $G_{KK}^*$ resonance with $c = 1$, a scalar with a mass of $280$ GeV, and SM non-resonant Higgs boson pair production, are also shown. The scalar sample is normalized to a cross section times branching ratio of $2.7$ pb. The quoted uncertainties include both the statistical and systematic uncertainties, and the total uncertainty considers correlations. The numbers of observed and predicted events are also given in the control region.

101
Figure 8.7 shows comparisons of the predicted $m_{4j}$ background distributions to those observed in the 2015 and 2016 datasets. A few signal models are also displayed. The scalar sample shown is normalized to a cross section times $b \rightarrow b\bar{b}$ branching ratio of 2.7 pb, which is the best-fit value. The predicted background and observed distributions are mostly in agreement, with an excess above the predicted background in one bin around 280 GeV.

8.3 Statistical analysis

Following the statistical procedures outlined in Ref. 78, a test statistic based on the profile likelihood ratio 79 is used to test hypothesized values of $\mu = \sigma/\sigma_{\text{model}}$, the global signal strength factor, separately for each signal model. The exclusion limits are computed using asymptotic formula 79 and are based on the $CL_s$ method 80, where a value of $\mu$ is regarded as excluded at the 95% confidence level (CL) when $CL_s$ is less than 5%.
The test statistic used is a one-sided profile likelihood ratio:

\[ q_0 = -2 \ln \frac{L(\alpha, \hat{\theta}(o))}{L(\hat{\mu}, \hat{\theta})}; \hat{\mu} > 0 \]

(8.1)

\[ q_0 = 0; \hat{\mu} < 0 \]

(8.2)

where \( \mu \) is the value of the signal normalization considered, and \( \hat{\mu} \) is the maximum likelihood (ML) value of \( \mu \). \( \hat{\theta} \) is the set of nuisance parameters (NP): \( \hat{\theta} \) is the ML value of \( \hat{\theta} \) and \( \hat{\theta} \) is the ML value of \( \hat{\theta} \) when \( \mu \) is fixed at a particular value. \( L \) denotes the profile likelihood: \( L(\hat{\mu}, \hat{\theta}) \) is the likelihood where \( \mu \) is allowed to take any value, the unconstrained likelihood. \( L(\alpha, \hat{\theta}(o)) \) is the likelihood for the value of \( \mu = 0 \), the constrained likelihood.

This tests the compatibility of the data with the background-only hypothesis, \( \mu = 0 \). The local \( p \)-value of a set of data, \( p_0 \), is defined as the probability for the background-only hypothesis to have a value of \( q_0 \) that is higher than the value of \( q_0 \) in that data. In order to obtain \( p_0 \), pseudo-experiments are generated with the background-only model, and the distribution of the test statistic, \( q_0 \), is built up from the values of the pseudo-experiments.

The background model is found to describe the data, and no significant excess is observed. The smallest local \( p_0 = 0.175 \) \( (1 \sigma) \) is found at 1100 GeV when fitting with the narrow scalar model. The local \( p_0 \) values for the three signal models as a function of the resonance mass are shown in Fig. 8.8.

Figure 8.9 shows the pulls of the systematic uncertainty nuisance parameters and their correlations for the 2000 GeV mass point. The parameters are ranked by their post-fit impact on \( \hat{\mu} \). Only the leading 30 nuisance parameters are displayed. One nuisance parameter (QCD.ShapeCRHigh) in both the 2\( b \) and 3\( b \) samples shows a significant constraint coming from the signal region data. This nuisance parameter corresponds to the shape uncertainty on the QCD background derived.
Figure 8.8: Local $p_0$ of the (a) scalar, (b) $G^\ast_{KK}$ with $\epsilon = 1$, and (c) $G^\ast_{KK}$ with $\epsilon = 2$.

from the $2b$ and $3b$ control regions, as explained in section 7.5. The prior probability distributions for this nuisance parameter are very broad. The relative uncertainty on the background prediction is extremely high at high $m_{J^J}$. This is because there is very little data in the control region at high mass to constrain this uncertainty.

Examples of the fit used to set these limits are shown in Figure 8.10, where a narrow-width scalar $H$ is used for the signal model. In cases where the best-fit is negative, the fit is repeated with $\mu$ bounded to zero. At 2 TeV, the fitted signal is positive ($\mu = 0.1 \pm 0.25$) though consistent with the background-only hypothesis. In all fits, good agreement is seen between data and the background only model.
Figure 8.9: The impact of nuisance parameters on the fitted cross section, ranked by their post-fit impact. The signal mass used in these fits is 2000 GeV, and the signal model is (a) narrow scalar, (b) $G_{KK}$ with $c = 1$, and (c) $G_{KK}$ with $c = 2$.

The observed limit for the narrow scalar and $G_{KK}$ are shown in Figures 8.11, 8.12, and 8.13. The stat-only limit is also shown. The impact of systematic uncertainties is small. These limits do not contain any input from the resolved analysis.

8.4 Boosted and resolved combined limits

The observed limits for the Graviton models is shown in Figure 8.14 for $c = 1$ and in Figure 8.15 for $c = 2$. The observed limit for the narrow scalar is shown in Figure 8.16. The bulk RS model with $c = 1$ is excluded for masses between 313 and 1362 GeV, and the bulk RS model with $c = 2$ is
Figure 8.10: Post-fit signal region scaled $m_{2J}$ distributions after fitting the data with the 2 TeV $G_{KK}^e$ with $\epsilon = 1.0$ hypothesis. The signal strength is slightly positive.

excluded for masses below 1744 GeV. In the heavy Higgs model, the cross section upper limits for $\sigma(pp \rightarrow H \rightarrow hh \rightarrow bbb)$ range from 1 to 10 fb in the 1000 to 3000 GeV mass range.

Different expected exclusion limits from the analysis can be compared in Figure 8.16. The resolved analysis is only sensitive to resonance searches up to 900 GeV. The boosted 4$b$ is most sensitive for resonances between 1200 and 1800 GeV. The boosted 3$b$ is most sensitive for resonances between 2000 and 2500 GeV. The boosted 2$b$ is most sensitive for resonances between 2500 and 3000 GeV. The combination significantly improves the sensitivity between 1 and 1.5 TeV for resonant signals. The result is limited by systematic uncertainties in the background normalization and shape. Since
Figure 8.11: The expected and observed 95\% CL upper exclusion limits for the boosted analysis calculated including all systematic uncertainties for the narrow scalar model. The dot-dashed line shows the expected limit when only statistical uncertainties are included. The limits are derived with the asymptotic approximation.

Figure 8.12: The expected and observed 95\% CL upper exclusion limits for the boosted analysis calculated including all systematic uncertainties for the $c = 1.0$ Graviton. The dot-dashed line shows the expected limit when only statistical uncertainties are included. The limits are derived with the asymptotic approximation.
Figure 8.13: The expected and observed 95% CL upper exclusion limits for the boosted analysis calculated including all systematic uncertainties for the $c = 2.0$ Graviton. The dot-dashed line shows the expected limit when only statistical uncertainties are included. The limits are derived with the asymptotic approximation.

these are data-driven, an increase of the integrated luminosity will improve the sensitivity.

The non-resonant search is performed using the resolved analysis only, since it has much better sensitivity to non-resonant signals than the boosted analysis. Using SM di-Higgs non-resonant production via gluon–gluon fusion as the signal model and applying the NNLO and finite top-quark mass correction, the observed 95% CL upper limit is $\sigma(pp \rightarrow hh \rightarrow b \bar{b}b \bar{b}) < 147$ fb. The expected and observed limit values and the associated uncertainties are given in Table 8.3. The observed limit is stronger than the expected due to the slight deficit of events in $m_{4j}$ around 500 – 600 GeV.

Table 8.3: 95% CL exclusion limits for SM non-resonant di-Higgs production, in units of the SM predicted value for $\sigma(pp \rightarrow hh \rightarrow b \bar{b}b \bar{b})$.

The searches for di-Higgs production have a short history, but they will have a long future. This thesis presents a search for both resonant and non-resonant production of pairs of Standard Model Higgs bosons in the dominant $b\bar{b}b\bar{b}$ channel, using 36.1 fb$^{-1}$ of LHC $pp$ collision data at $\sqrt{s} = 13$ TeV collected by ATLAS in 2015 and 2016. The search sensitivity of this analysis exceeds that of the previous analysis of the $\sqrt{s} = 13$ TeV 2015 dataset\textsuperscript{81} for non-resonant signal and also across the entire mass range of 260 to 3000 GeV for the resonance search, with significant improvement in the high mass resonance region. The resolved analysis reconstructs each $b \rightarrow b\bar{b}$ decay as two separate $b$-tagged jets, while the boosted analysis reconstructs each $b \rightarrow b\bar{b}$ decay as a single large-radius jet associated with at least one small-radius $b$-tagged track jet. The estimated background consists mainly of multi-jet and $t\bar{t}$ events.
No significant excess is observed in the data. Upper limits at 95\% confidence level on the production cross-section times branching ratio to the $bb\bar{b}$ final state are set for a narrow-width spin-0 scalar and for wider spin-2 resonances. The bulk RS model with $c = 1$ is excluded for masses between 313 and 1362 GeV, and the bulk RS model with $c = 2$ is excluded for masses below 1744 GeV. The upper limit on the non-resonant production is 147 fb, which corresponds to $13.0 \times$ the SM expectation. This result confirms the great success of the Standard Model. In light of these results, the Higgs potential shape at the TeV energy scale is currently consistent with the SM prediction. Without any significant excess, the phase space for beyond the Standard Model physics is further constrained.

Increased sensitivity with future Run 2 and beyond datasets could come through efficiency improvements in $b$-tagging for the high $p_T$ jets. Other improvements involve advanced trigger technologies, which would increase the number of signal events recorded, as well as improvements in jet energy and mass resolution, which would increase the purity of the signal selection. These improvements, combined with a larger dataset, may double the current resonance search sensitivity. For the non-resonance search, a combined sensitivity of $|\lambda|_{\text{SM}} \sim 10$ is possible at the end of Run 2 in 2020.

Di-Higgs searches and measurements will continue to be some of the most important analyses. These measurements can show hints of the physics beyond the Standard Model. After the 2030 to 2040 run, the High Luminosity LHC will be able to constrain $|\lambda|_{\text{SM}} \sim 1$ with all the different channels from both ATLAS and CMS combined. Future electron-electron colliders can produce di-Higgs events from ZH channel and could further constrain $|\lambda|_{\text{SM}} \sim 0.3$. This measurement requires combined advances in accelerator and detector technology, computation, and theoretical precision\textsuperscript{82,83}.
Life is short, and the understanding of the universe is an endless journey. I am deeply honored to have been a small part of this odyssey by working on the boosted $pp \to hh \to b\bar{b}b\bar{b}$ analysis.
Does your passion for power consume your soul?

Do you thirst for knowledge no matter the cost?

Can you feel your instincts overwhelm your reason?

Boosted sideband region kinematic distributions

This appendix shows comparisons of data with predictions of QCD multi-jets and $t\bar{t}$ backgrounds in the sideband region. The definition of the sideband region is discussed in Section 6.2.

Because of the fit method in Section 6.5, the predicted normalization agrees perfectly with data. The
agreement of the data and predictions is generally very good, without significant deviations.

Figures A.1, A.2, A.3, and A.4 show predictions of various kinematics of the large-\(R\) jets and their associated track jets in the 4\(b\) channel. Figures A.5, A.6, A.7, and A.8 show predictions of various kinematics of the large-\(R\) jets and their associated track jets in the 3\(b\) channel. Figures A.9, A.10, A.11, and A.12 show predictions of various kinematics of the large-\(R\) jets and their associated track jets in the 2\(b\) channel.

Figure C.5: Kinematics ($p_T$, mass, $\eta$, $\phi$) of the leading large-$R$ jet in data and prediction in the signal region after requiring 3 $b$-tags.
Figure C.6: Kinematics ($p_T$, mass, $\eta$, $\phi$) of the subleading large-$R$ jet in data and prediction in the signal region after requiring 3 $b$-tags.
Figure C.7: The first two rows show the $p_T$ of the leading (left) and subleading (right) small-$R$ track jets associated to the lead (first-row) and sub-lead (second-row) large-$R$ jet in data and prediction in the signal region after requiring 3 $b$-tags. The third row shows the $\Delta R$ between two leading small-$R$ track-jets associated to the leading (left) and subleading (right) large-$R$ jet.
Figure C.8: Kinematics (invariant mass, $\Delta R$, $\Delta \eta$ and $\Delta \phi$) of the two large-$R$ jets in data and prediction in the signal region after requiring 3 $b$-tags.
Figure C.9: Kinematics ($p_T$, mass, $\eta$, $\phi$) of the leading large-$R$ jet in data and prediction in the signal region after requiring 2 $b$-tags split.
Figure C.10: Kinematics ($p_T$, mass, $\eta$, $\phi$) of the subleading large-$R$ jet in data and prediction in the signal region after requiring 2 $b$-tags split.
Figure C.11: The first two rows show the $p_T$ of the leading (left) and subleading (right) small-$R$ track jets associated to the lead (first-row) and sub-lead (second-row) large-$R$ jet in data and prediction in the signal region after requiring 2 $b$-tags split. The third row shows the $\Delta R$ between two leading small-$R$ track-jets associated to the leading (left) and subleading (right) large-$R$ jet.
Figure C.12: Kinematics (invariant mass, $\Delta R$, $\Delta \eta$ and $\Delta \phi$) of the two large-$R$ jets in data and prediction in the signal region after requiring 2 $b$-tags split.
The treasure in my mind is greater than any worldly glory.

Constant $\mu_{\text{qcd}}$ Validation

One important assumption of this analysis is the constancy $\mu_{\text{qcd}}$ across different regions on the 2D $m_{j}^{\lead}-m_{j}^{\subl}$ plane. This can be validated in data, excluding signal regions, which were blinded during this check. The $\bar{t}t$ contribution is estimated directly from MC and subtracted in the data distributions. The ratio of the number of $n$-$b$-tagged events versus the number of less-$b$-tagged events in each $m_{j}^{\lead}-m_{j}^{\subl}$ bin is calculated. The pull of the ratios in SB/CR/SR is also calculated.
These two distributions shows the consistency of $\mu_{\text{qcd}}$ in SB/CR/SR, as seen in Figures D.1 (1b over 0b), D.2 (2b over 1b), D.3 (2bs over 1b), D.4 (3b over 2b), D.5 (4b over 2b). Table 6.5 compares the $\mu_{\text{qcd}}$ value in the 4b/3b/2bs channels. This validates the choice of sideband region and the assumption of $\mu_{\text{qcd}}$ as constant in the analysis.

![Figure D.1](image-url)

**Figure D.1:** 1b over 0b $\mu_{\text{qcd}}$ values evaluated in data, with the $N_{\text{event}}$ weighted mean and the Gaussian fit mean listed.

Also, the dijet MC can be used for constant $\mu_{\text{qcd}}$ validation. The same distributions evaluated in dijet MC are shown in Figure D.6 (1b over 0b), D.7 (2b over 1b), D.8 (2bs over 1b), D.9 (3b over 2b), D.10 (4b over 2b). Poor statistics of the dijet MC samples affects the pull distributions, especially in 3b and 4b, yet the consistency of $\mu_{\text{qcd}}$ in SB/CR/SR is still validated. The large difference in $\mu_{\text{qcd}}$ between data and MC also shows that the dijet MC should not be used directly for background estimation.
Figure D.2: $\mu_{qcd}$ values evaluated in data, with the $N_{event}$ weighted mean and the Gaussian fit mean listed.

Figure D.3: $\mu_{qcd}$ values evaluated in data, with the $N_{event}$ weighted mean and the Gaussian fit mean listed.
Figure D.4: $\sqrt{s}$ over $z b \mu_{\text{qcd}}$ values evaluated in data, with the $N_{\text{event}}$ weighted mean and the Gaussian fit mean listed. The signal region is blinded.

Those who know only one path to victory can never hope to triumph.

E

Reweighting Details

The first iteration, second iteration, and last iteration of reweighting fits for 2b, where in 1b data, the non-\(b\)-tagged Higgs candidate are reweighted to be like a 1b tagged Higgs candidate, are shown in Figures E.1 and E.2. Similar distributions for 3b, where in 2b data, the non-\(b\)-tagged Higgs candidate are reweighted to be like a 1b tagged Higgs candidate, are shown in Figures E.3 and E.4. Similar distributions for 4b, where in 2b data, the non-\(b\)-tagged Higgs candidate are reweighted to be like a
2b tagged Higgs candidate, are shown in Figures E.5 and E.6. The distributions before reweighting (first row), the reweighting results after the first iteration (second row), and the final distributions after reweighting (last row) are presented.

In the some plots, like Figures E.5 and E.6, the last ratio bin sometimes still does not converge to unity. This is a feature from the limited statistics in the last bin, especially in 4b case, where only 20% 2b events are used for background prediction and therefore reweighted. To make this fit fully converge, a different binning or more iterations could be used. Nevertheless, the last bin’s few events would also likely end up with a large unphysical weight and therefore harm the background prediction later.

A comparison of the SB shapes before and after reweighting for the 2bs, 3b, and 4b channels are shown in Figures E.7, E.8, and E.9. Also, a comparison of the CR shapes before and after reweighting for the 2bs, 3b and 4b channels can be seen in Figures E.10, E.11, and E.12. In almost all cases, both the reweighted and the non-reweighted predictions agree fairly well with data, and the reweighted plots’ Kolmogorov–Smirnov (KS) test scores are greater than those from non-reweighted distributions.

More reweighting methods are tested to further validate the nominal reweighting method. The original method tries to reweight the non-b-tagged Higgs candidate in the lower b-tagged region to be like a b-tagged Higgs candidate. This AddTag reweighting is done on three variables: the large-R jet $p_T$ and the two track jet $p_T$’s, which is counted as one iteration of reweighting.
Figure E.1: For all background estimate: the fits to the ratio of the data in the $ib$ category of the subleading Higgs candidate $ib$-tagged events' subleading Higgs candidate distributions (black points), over the leading Higgs candidate $ib$-tagged events' subleading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet’s leading track jet $p_T$ (middle), and large-$R$ jet’s subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.
Figure E.2: For $q\bar{b}s$ background estimate: the fits to the ratio of the data in the $ib$ category, of the leading Higgs candidate $ib$-tagged events' leading Higgs candidate distributions (black points), over the subleading Higgs candidate $ib$-tagged events' leading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet's leading track jet $p_T$ (middle), and large-$R$ jet's subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.
For $b\bar{b}$ background estimate: the fits to the ratio of the data in the $\pm b$ category, of the subleading Higgs candidate $\pm b$-tagged events' subleading Higgs candidate distributions (black points), over the leading Higgs candidate $\pm b$-tagged events' subleading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet's leading track jet $p_T$ (middle), and large-$R$ jet's subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.
Figure E.4: For \(3b\) background estimate: the fits to the ratio of the data in the \(\pm b\) category, of the leading Higgs candidate \(3b\)-tagged events' leading Higgs candidate distributions (black points), over the subleading Higgs candidate \(3b\)-tagged events' leading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-\(R\) jet \(p_T\) (left), the large-\(R\) jet's leading track jet \(p_T\) (middle), and large-\(R\) jet’s subleading track jet \(p_T\) (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.
Figure E.5: For $4b$ background estimate: the fits to the ratio of the data in the $2b$ category, of the subleading Higgs candidate $2b$-tagged events' subleading Higgs candidate distributions (black points), over the leading Higgs candidate $2b$-tagged events' subleading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet’s leading track jet $p_T$ (middle), and large-$R$ jet’s subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.
Figure E.6: For $4b$ background estimate: the fits to the ratio of the data in the $Zb$ category, of the leading Higgs candidate $Zb$-tagged events’ leading Higgs candidate distributions (black points), over the subleading Higgs candidate $Zb$-tagged events’ leading Higgs candidate distributions (yellow). Distributions and fits to the estimated QCD background for large-$R$ jet $p_T$ (left), the large-$R$ jet’s leading track jet $p_T$ (middle), and large-$R$ jet’s subleading track jet $p_T$ (right) are shown. Figures are before reweighting (top row), after the first iteration (second row), after the fourth iteration (third row), and after the last iteration (bottom row). The green line is the spline fit; the red line is a polynomial fit; the blue line is the spline interpolation.
Figure E.7: Reweighed $Z\ell\ell$ sideband region prediction comparisons. The top row is the $m_{4\ell}$; the second row is leading large-$R$ jet $p_T$; the third row is the leading large-$R$ jet's leading track $p_T$; and the last row subleading large-$R$ jet's leading track $p_T$. On the left are the distributions before reweighting, and on the right are the distributions after reweighting.
Figure E.8: Reweighed 3b sideband region prediction comparisons. The top row is the \( m_{jj} \); the second row is leading large-\( R \) jet \( p_T \); the third row is the leading large-\( R \) jet’s leading track \( p_T \); and the last row subleading large-\( R \) jet’s leading track \( p_T \). On the left are the distributions before reweighting, and on the right are the distributions after reweighting.
Figure E.9: Reweighted $\ell b$ sideband region prediction comparisons. The top row is the $m_{jj}$; the second row is leading large-$R$ jet $p_T$; the third row is the leading large-$R$ jet's leading track jet $p_T$; and the last row subleading large-$R$ jet's leading track jet $p_T$. On the left are the distributions before reweighting, and on the right are the distributions after reweighting.
Figure E.12: Reweighted $\Delta \phi$ control region prediction comparisons. The top row is the $m_2j$; the second row is leading large-$R$ jet $p_T$; the third row is the leading large-$R$ jet’s leading track $p_T$; and the last row subleading large-$R$ jet’s leading track $p_T$. On the left are the distributions before reweighting, and on the right are the distributions after reweighting.
Other reweighting methods that share similar idea with the AddTag method where \(1/2b\) samples are inclusively reweighted have been tested:

- `bkgeta`: AddTag reweighting, but on four variables: large-\(R\) jet \(p_T\), the two track jet \(p_T\)'s, and large-\(R\) jet \(\eta\).

- `bkgdr`: AddTag reweighting, but on four variables: large-\(R\) jet \(p_T\), the two track jet \(p_T\)'s, and two track jet \(\Delta R\).

- `bkgtrk`: AddTag reweighting, but on two variables: only the two track jet \(p_T\)'s.

- `bkgsb`: AddTag reweighting, using the same three variables but instead of reweighting the \(1b\) non-tagged Higgs candidate to be like a \(1b\) tagged Higgs candidate, reweight \(1b\) non-tagged Higgs candidate's distributions to be like a \(2bs\) Higgs candidate in the sideband. Similarly, for \(3b\) channel, reweight \(2b\) non-tagged Higgs candidate's distributions to be like the \(3b\) Higgs candidate in the sideband. And for \(4b\) channel, reweight \(2b\) non-tagged Higgs candidate's distributions to be like the \(4b\) Higgs candidate in the sideband.

The previous analysis's method of reweighting the \(1b\) sideband directly to be like \(2bs\) sideband, and propagating the weight to the control and signal regions has also been tested:

- `leadtrk`: on three variables: leading Higgs candidate large-\(R\) jet \(p_T\), the two lead-track jet \(p_T\)'s.

- `subltrk`: on three variables: leading Higgs candidate large-\(R\) jet \(p_T\), the two subleading-track jet \(p_T\)'s.

- `alltrk`: on five variables: leading Higgs candidate large-\(R\) jet \(p_T\), the two lead-track jet \(p_T\)'s, and the two subleading-track jet \(p_T\)'s.
The $m_{3\ell}$ distribution comparisons are shown in Figure E.13. The signal regions are blinded, and the data distribution is replaced with the non-reweighted background estimate. For track jet $p_T$ distributions, the comparisons are shown in Figures E.14, E.15, and E.16. In most cases, the $\chi^2$ per degrees of freedom is improved for the background estimations, and very similar distributions in the signal region are observed. Hence, no extra systematics are assigned for the reweighting method.

The reweighting method can be further validated using dijet MC. Only $2bs$ dijet MC has enough statistics for testing. The weights derived in data are applied in the MC $1b$ using the AddTag method and compared with the $1b$ un-reweighted distribution and the $2bs$ distribution. The inclusive region (sideband + control + signal) track jet $p_T$ distributions are shown in Figure E.17. As can be seen, reweighting helps to model different $b$-tagging sculpting effect. The $m_{3\ell}$ distributions can be seen in Figure E.18. Reweighting improves the overall $\chi^2$ per degrees of freedom agreement while introducing minimal differences with non-reweighted distributions.
Figure E.13: Reweighted $Zb$ (left column), $Zb$ (middle column), and $4b$ (right column) sideband (top row), control (middle row), and signal (bottom row) region prediction comparisons, for MJJ. The Signal region is blinded, and the data distribution is replaced with the non-reweighted background predictions.
Figure E.14: Reweighted ±6σ sideband (top row), control (middle row), and signal (bottom row) region prediction comparisons, for leading Higgs Candidate leading track jet $p_T$ (first column), leading Higgs Candidate subleading track jet $p_T$ (second column), subleading Higgs Candidate leading track jet $p_T$ (third column), subleading Higgs Candidate subleading track jet $p_T$ (fourth column). The signal region is blinded, where the distribution is replaced with the non-reweighted predictions.
Figure E.15: Reweighted $\tilde{\nu}$ sideband (top row), control (middle row), and signal (bottom row) prediction comparisons, for leading Higgs Candidate leading track jet $p_T$ (first column), leading Higgs Candidate subleading track jet $p_T$ (second column), subleading Higgs Candidate leading track jet $p_T$ (third column), subleading Higgs Candidate subleading track jet $p_T$ (fourth column). The signal region is blinded, where the distribution is replaced with the non-reweighted predictions.
Figure E.16: Reweighted $q\bar{q}$ sideband (top row), control (middle row), and signal (bottom row) region prediction comparisons, for leading Higgs Candidate leading track $p_T$ (first column), leading Higgs Candidate subleading track jet $p_T$ (second column), subleading Higgs Candidate leading track jet $p_T$ (third column), subleading Higgs Candidate subleading track jet $p_T$ (fourth column). The signal region is blinded, where the distribution is replaced with the non-reweighted predictions.
Figure E.17: Reweighted $2b$ inclusive region prediction comparisons in dijet MC, for leading Higgs Candidate leading track jet $p_T$ (top left), leading Higgs Candidate subleading track jet $p_T$ (top right), subleading Higgs Candidate leading track jet $p_T$ (bottom left), subleading Higgs Candidate subleading track jet $p_T$ (bottom right). $1b$ and reweighted $1b$ distributions are normalized to $2bs$. 
Figure E.18: Reweighted $Z_b s$ sideband (top) / control (middle) / signal (bottom) region prediction comparisons, for MJJ. The signal region is not blinded, since it is dijet MC distribution. $1b$ and reweighted $1b$ distributions are normalized to $Z_b s$. 
A fruit must rot before its seed can sprout.

Validations with low mass and high mass signal region

Another check is the so-called “low mass signal region” (or ZZ region) and “high mass signal region” (or TT region). On the $m_{j_{\text{lead}}}-m_{j_{\text{subl}}}$ 2D plane, a lower in center (ZZ) and higher in center
(TT) signal region are defined:

\[ X_{ZZ} = \sqrt{\left( \frac{m^\text{lead}_j - 103 \text{ GeV}}{0.1 \left( m^\text{lead}_j \right)} \right)^2 + \left( \frac{m^\text{subl}_j - 96 \text{ GeV}}{0.1 \left( m^\text{subl}_j \right)} \right)^2 } \]  \hspace{1cm} (F.1)

\[ X_{TT} = \sqrt{\left( \frac{m^\text{lead}_j - 164 \text{ GeV}}{0.1 \left( m^\text{lead}_j \right)} \right)^2 + \left( \frac{m^\text{subl}_j - 155 \text{ GeV}}{0.1 \left( m^\text{subl}_j \right)} \right)^2 } \]  \hspace{1cm} (F.2)

They are shown in Figure F.1. The signal region background is estimated using the same sideband and control regions with events contained in the ZZ or TT signal region excluded. Then these fake signal regions are unblinded and compared with the prediction. This comparison validates the background estimation strategy in QCD and \( t \bar{t} \) enriched regions.

![Figure F.1: Illustration of ZZ and TT signal regions on the 2D \( m_j^\text{lead} - m_j^\text{subl} \) plane. The white circle in the middle is the blinded real signal region.](image-url)
The differences between data and prediction in the ZZ and TT signal regions are summarized in Tables F.1 and F.2. The kinematic distribution of data and prediction in the ZZ and TT signal regions are shown in Figures F.2 and F.3. The differences between data and prediction are comparable with data statistical uncertainties.

No person was ever honored for what he received. Honor has been the reward for what he gave.

Discussion on systematic uncertainties

G.1 Uncertainty on $t\bar{t}$ generator

In addition to the $t\bar{t}$ fit uncertainties, additional $t\bar{t}$ MC samples are considered with the following variations: hadronization (Had), fragmentation (Frag), additional radiation (Rad), and top quark mass (Mass). The variation in total background, with different $t\bar{t}$ MC samples as input is tested. These $t\bar{t}$ simulations are used to replace the nominal $t\bar{t}$ MC and are stitched with the high $m_{t\bar{t}}$ sam-
The variations in the 2bs signal region prediction are shown in Figure G.1. This uncertainty is considered to be limited by the MC statistical uncertainties, and therefore no $\bar{t}t$ MC uncertainty is applied.

**Figure G.1:** $2bs$ channel signal region $m_{J_\text{total}}$ total background (QCD + $\bar{t}t$) predictions with different $\bar{t}t$ MC variations. The different variations agree with the nominal $\bar{t}t$ MC within the statistical uncertainties.

### G.2 Uncertainty on the shape of $\bar{t}t$ $m_{J_\text{total}}$ in the 4/3b signal region

Because the $\bar{t}t$ 4/3b sample is statistically limited, the $2bs$ $\bar{t}t$ $m_{J_\text{total}}$ shape is used to predict the $\bar{t}t$ background shape in the 4/3b signal regions. In order to estimate this shape uncertainty, the $2bs$ and $3b$ sideband shapes are normalized and compared in Figure G.2. To avoid large statistical uncertainties, the distributions of the $3b$ and $2b$ are smoothed. The ratio of the two smoothed distributions is taken an additional $\bar{t}t$ shape systematic. This ratio is used to scale the $\bar{t}t$ background prediction in the signal region while keeping the same $\bar{t}t$ yield.
Figure G.2: The shape of $t\bar{t}$ $m_{3J}$ in the sideband region, comparing the $3b$ shape with that of the $2bs$, in order to assess the systematic effect of additional $b$-tags changing the dijet mass distribution. The $m_{3J}$ distribution is shown on the left, and the ratio as a function of $m_{3J}$ between $3b$ and $2bs$ distributions is shown on the right.

G.3 Uncertainty on smoothing function in the signal region

While the function shown in Equation 6.7 fits the predicted signal region $m_{3J}$ distribution well, it does not have a concrete, physical motivation. Two checks are performed by varying the fit range and the fit function. The checks show the smoothing function variations are almost always smaller than the statistical uncertainties of the distributions. This gives this systematic uncertainty strong correlation with the shape uncertainties discussed in the previous section. As a result, this systematic uncertainty is excluded. Nevertheless, the tests are discussed below.

To test the impact of fit range, the upper bounds are varied to be $\{2800, 3000, 3200\}$ GeV and the lower bounds are varied to be $\{1200, 1300, 1400\}$ GeV. The ratio of the fits for each upper bound to that of the nominal (1200-3000 GeV) are shown in Figure G.3, along with a hash band showing the statistical uncertainty of the nominal fit. This is estimated separately for $2bs$, $3b$, and $4b$ samples.
Fits in which the fit $\chi^2$ per degree of freedom probability is less than 0.001%, or in which the fit integrals between 1500-2000 GeV, 2000-2500 GeV, or $>2500$ GeV are not in agreement with the original distribution within a factor of 2 or 0.5, are not used to estimate the uncertainty. This ensures that poor fits are not used to estimate the uncertainty.

Figure G.3: Dijet mass distribution SR prediction fit with several fit ranges (left) and the ratio of nominal to fits with different fit ranges (right) for the $2b$ (top), $3b$ (middle) and $4b$ (bottom) samples.
The signal region QCD prediction is also fit with a variety of distributions which have power law behavior in the bulk of the distribution. The set of additional functions examined (labeled MJ1-MJ7) can be found in Table G.1, where \( x = m_{JJ}/\sqrt{s} \).

Table G.1: Functions used to fit the QCD dijet mass distributions, where \( x = m_{JJ}/\sqrt{s} \).

Figure G.4 shows the fits to the QCD prediction in the \( 4b/3b/2b \) signal regions, the nominal dijet fit, and the ratios of the nominal fit to that of the additional functions. As before, poor fits are not used to estimate the uncertainty.
Figure G.4: Dijet mass distribution SR prediction fit with several fit functions (left) and the ratio between the nominal function fit result and the fit results with different fit functions (right) for the 2$b$ (top), 3$b$ (middle), and 4$b$ (bottom) samples. The additional fit functions are from Table G.1.
Effects from variations in the sideband and control region definitions

This Appendix is the supporting material for section 7.4. The effect on signal region yield from different control region and sideband region definitions is tested. All these tests are done on the control/sideband regions after the full reweighting procedure as described in 6.6 while applying the
nominal reweighting values.

In addition to the nominal control region and sideband region definitions, seven additional variations, as illustrated in Figures H.2, H.1, H.3, H.5, H.4, H.7, H.6. They are defined in section 7.4.

The high mass and low mass CR test how background modeling is sensitive to the exact position of CR. The signal-depletion CR is designed to test whether there is significant signal contamination in the CR. If there is a large amount of signal contamination in CR, the agreement between data and prediction in the CR would be significantly different from the number calculated with nominal CR. The sideband variations are designed to test how sensitive the normalization fit is to the sideband definition.

The agreement between data and prediction in CR are summarized in Tables 7.1, 7.2, and 7.3. For most CR variations, the discrepancy between data and prediction is smaller than the statistical uncertainty of data. The only exception is $2b$s high CR variation, where the prediction is $\sim 1.5\sigma$ away from the data. The signal-depletion CR definition shows no significant deviation in yield from the nominal CR definition. The discrepancy is within the statistical uncertainty of data as well. This shows that no significant signal contamination in the CR is found.
Figure H.1: In $t\bar{b}$ data, with the low-mass CR variation, new SB and CR $m_{J}^{\text{lead}}$-$m_{J}^{\text{subl}}$ distributions.

Figure H.2: In $t\bar{b}$ data, with the high-mass CR variation, new SB and CR $m_{J}^{\text{lead}}$-$m_{J}^{\text{subl}}$ distributions.
Figure H.3: In $\nu b$ data, with the signal-depletion (small) CR variation, new SB and CR $m_{J}^{\text{lead}} - m_{J}^{\text{subl}}$ distributions.

Figure H.4: In $\nu b$ data, with the low-mass SB variation, new SB and CR $m_{J}^{\text{lead}} - m_{J}^{\text{subl}}$ distributions.
Figure H.5: In $t\bar{b}$ data, with the high-mass SB variation, new SB and CR $m_{J^{lead}}-m_{J^{subl}}$ distributions.

Figure H.6: In $t\bar{b}$ data, with the small SB variation, new SB and CR $m_{J^{lead}}-m_{J^{subl}}$ distributions.
Figure H.7: In $ib$ data, with the large SB variation, new SB and CR $m_{\text{lead}}^{\text{subl}}$ distributions.
The whole background estimation procedure is repeated after the variation. Summaries of background estimated yields for $4b$ region can be found in Tables H.1, H.2, H.3, H.4, H.5, H.6, and H.7, for each variation.

</table>
The variations of prediction in SR can be found in Tables H.22, H.23 and H.24. The variation in the signal-depletion variation is not shown since it is zero by definition. The variations in background prediction in the SR are very small and within statistical uncertainty. This is mainly due to the data-driven background estimation technique used.

Table H.22: Variations in the 4\textit{b} channel signal region prediction.

</table>

In addition to the normalization, the variation of QCD shape in SR is also tested, as shown in Figures H.8 and H.9. There are very small variations in terms of QCD shape, and such variation is within QCD shape uncertainty derived from the nominal CR.
Figure H.8: Comparisons of the nominal QCD shape prediction (black) with the results of control and sideband region variations (red). The ratio of the shape from each variation to the nominal shape is shown in the lower panel. The left column shows the relevant distributions for the 4$b$ signal region, the middle column is for the 3$b$ signal region, and the left column is for the 2$b$ signal region. The top row is for the high CR variation, the middle row is for the low CR variation, and the bottom row is for the small CR variation.
Figure H.9: Comparisons of the nominal QCD shape prediction (black) with the results of control and sideband region variations (red). The ratio of the shape from each variation to the nominal shape is shown in the lower panel. The left column shows the relevant distributions for the $4\bar{b}$ signal region, the middle column is for the $3\bar{b}$ signal region, and the left column is for the $2\bar{b}$ signal region. The top row is for the high SB variation, the second row is for the low SB variation, the third row is for the small SB variation and the large raw is for the large SB variation.
Table H.24: Variations in the $Z\ell\ell$ channel signal region prediction.
