Charged-particle angular correlations in XeXe collisions at $\sqrt{s_{NN}} = 5.44$ TeV

The CMS Collaboration

Abstract

Azimuthal correlations of charged particles in xenon-xenon collisions at a center-of-mass energy per nucleon pair of $\sqrt{s_{NN}} = 5.44$ TeV are studied. The data were collected by the CMS experiment at the LHC with a total integrated luminosity of $3.42 \, \mu\text{b}^{-1}$. The collective motion of the system formed in the collision is parameterized by a Fourier expansion of the azimuthal particle density distribution. The azimuthal anisotropy coefficients $v_2$, $v_3$, and $v_4$ are obtained by the scalar-product, two-particle correlation, and multi-particle correlation methods. Within a hydrodynamic picture, these methods have different sensitivities to non-collective and fluctuation effects. The dependence of the Fourier coefficients on the size of the colliding system is explored by comparing the xenon-xenon results with equivalent lead-lead data. Model calculations that include fluctuation effects are also compared to the experimental results. The observed angular correlations provide new constraints on the hydrodynamic description of heavy ion collisions.

1 Introduction

At sufficiently high temperatures or densities, lattice quantum chromodynamics predicts a transition from ordinary hadronic matter to a state of deconfined quarks and gluons, the so-called quark gluon plasma (QGP) (see, e.g., Ref. [1]). The QGP state can be reached through relativistic heavy ion collisions, where the collective behavior of the created medium manifests itself in azimuthal correlations among the emitted particles. These correlations have been studied in gold-gold collisions at the BNL RHIC [2–5], lead-lead (PbPb) collisions at the CERN LHC [6–9], as well as in collisions involving lighter nuclei, such as the copper-copper system studied at RHIC [10, 11]. More recently, collective behavior similar to that observed in collisions of heavy nuclei has also been found in high-multiplicity events produced in the proton-lead (pPb) system, and in proton-proton (pp) collisions [12–14]. The results from these small systems raise the question as to how the size of the colliding system affects the onset of QGP formation. Measurements from xenon-xenon (XeXe) collisions, as presented here, bridge the gap between the small (pp and pPb) and large (PbPb) systems previously studied at LHC energies.

Anisotropic flow can be characterized by a Fourier expansion [15–17],

\[
\frac{2\pi}{N} \frac{dN}{d\phi} = 1 + \sum_{n=1}^{\infty} 2v_n \cos[n(\phi - \Psi_n)],
\]

where \(dN/d\phi\) is the azimuthal particle density and \(\phi\) is the particle azimuthal angle with respect to a reference angle \(\Psi_n\). Different reference angles can be defined. The “participant plane” angle is the direction of the semi-minor axis of the region perpendicular to the beam direction spanned by the nucleons that undergo a primary interaction. The “event-plane” angle is defined by the direction perpendicular to the beam direction of the maximum outgoing particle density. In this paper the measured anisotropies are expressed in terms of the event-plane reference angle. Averaged over many events, the anisotropies measured with respect to the event plane are expected to be similar to those that would be obtained if it were possible to determine the actual participant plane.

The magnitude of the azimuthal anisotropy is characterized by the Fourier coefficients, \(v_n\). The second- and third-order Fourier coefficients are referred to as “elliptic” \((v_2)\) and “triangular” \((v_3)\) flow, respectively. The former reflects the lenticular shape of the collision overlap region, as well as initial-state fluctuations in the positions of nucleons at the moment of impact [18]. The latter is largely a consequence of fluctuations. While the \(v_2\) and \(v_3\) harmonics are believed to reflect the initial-state geometry [19], for \(n \geq 4\) the flow harmonics are also strongly affected by the dynamics of the system expansion. Hence, studying both the lower and higher flow harmonics is important for understanding the medium created in heavy ion collisions.

This analysis presents measurements of the charged-particle collective flow in XeXe collisions at a center-of-mass energy per nucleon pair of \(\sqrt{s_{NN}} = 5.44\text{ TeV}\). The results are shown as functions of transverse momentum, \(p_T\), for the pseudorapidity region \(|\eta| < 2.4\) and for different collision overlap geometries. Spectrum-weighted values with \(0.3 < p_T < 3.0\text{ GeV}/c\), with the efficiency-corrected yield in each \(p_T\) interval used as the weight, are also presented. The Fourier coefficients \(v_2, v_3, \) and \(v_4\) are obtained by two-particle correlations \((v_n\{2\})\), the scalar-product method \((v_n\{SP\})\), and multi-particle cumulant analyses \((v_n\{m\}, m = 4, 6, \) and \(8\)).

Event-by-event fluctuations in the spatial overlap geometry lead to method-dependent differences in the extracted \(v_n\) values [20]. The fluctuations cause an increase in the deduced \(v_n\) values found using two-particle correlations and the scalar-product method, as compared to the corresponding participant plane value, while the four-particle cumulant \(v_n\) results are decreased. For fluctuations that follow a two-dimensional Gaussian behavior, the flow harmonics
based on more than four particles are expected to be the same as the four-particle correlations results. Deviations from this common behavior can be used to estimate the higher-order moments of the fluctuation distribution. Comparison of flow coefficients measured by different methods probes the initial-state conditions.

The XeXe values are compared to the results from PbPb collisions at $\sqrt{s_{NN}} = 5.02$ TeV. The comparison with measurements from different collision systems, but with similar collision geometry, can give insight to the system size dependence of the anisotropic flow. Theoretical predictions are compared to the observed system size dependence of the flow harmonics. The results presented here provide new information on the initial-state geometry and its fluctuations, as well as the system size dependence of the medium properties.

## 2 The CMS detector

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter (HCAL), each composed of a barrel and two endcap sections. Forward calorimeters extend the pseudorapidity coverage provided by the barrel and endcap detectors. Muons are detected in gas-ionization chambers embedded in the steel flux-return yoke outside the solenoid. The hadron forward (HF) calorimeter uses steel as an absorber and quartz fibers as the sensitive material. The two HF calorimeters are located 11.2 m from the interaction region, one on each end, and together they provide coverage in the range $3.0 < |\eta| < 5.2$. These calorimeters serve as luminosity monitors, are used to establish the event centrality, and provide the event-plane information for the SP analysis. The HF calorimeters are azimuthally subdivided into $20^\circ$ modular wedges and further segmented to form $0.175 \times 10^\circ$ ($\Delta \eta \times \Delta \phi$) towers.

The silicon tracker measures charged particles within the pseudorapidity range $|\eta| < 2.5$. For nonisolated particles of $1 < p_T < 10$ GeV/c and $|\eta| < 1.4$, the track resolutions are typically $1.5\%$ in $p_T$ and $25$–$90$ ($45$–$150$) $\mu$m in the transverse (longitudinal) impact parameter [21]. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [22]. The detailed Monte-Carlo (MC) simulation of the CMS detector response is based on GEANT4 [23].

## 3 Events and track selection

Results based on data recorded by CMS during the LHC runs with XeXe collisions at $\sqrt{s_{NN}} = 5.44$ TeV in 2017, with an integrated luminosity of $3.42 \mu$b$^{-1}$, are compared to similar data obtained in 2015 from PbPb collisions at $\sqrt{s_{NN}} = 5.02$ TeV with an integrated luminosity of $26 \mu$b$^{-1}$. In both systems, only tracks with $|\eta| < 2.4$ and $p_T > 0.3$ GeV/c are used.

For the XeXe events, a hardware level (level-1) trigger required at least one tower of the HF calorimeters to be above a threshold that was fixed to maximize the number of events counted, while keeping low the noise contamination from electromagnetic scattering and from pileup (i.e., multiple interactions in the same or neighboring bunch crossings). This trigger also required the presence of both colliding bunches at the interaction point. The average online pileup fraction was 0.018 per event. In addition, a high-level trigger was applied that required a single track from the pixel detector. Events are further selected offline by requiring at least 3 GeV of energy being detected in each of three HF calorimeter towers on either side of the CMS detector and to have a reconstructed primary vertex, containing at least two tracks, located within 15 cm of the nominal collision point along the beam axis and within 0.2 cm in the
transverse direction. In addition, contamination from beam-gas interactions are suppressed by applying a filter where, for each event with more than 10 tracks, at least 25% of the tracks are required to satisfy a high purity \([21]\) track quality criteria. The event selection efficiency is 95%. The track reconstruction algorithm is similar to that used for pp collisions \([21]\).

For PbPb collisions, as compared to XeXe events, there is an additional level-1 trigger requirement of a coincidence between signals in the HF calorimeters on either side of the CMS detector. While offline event selection is similar for PbPb and XeXe events, for the PbPb events the filter to suppress beam-gas interaction is not applied and pileup contamination is controlled by following the procedure outlined in \([24]\).

To ease the computational load for high-multiplicity central PbPb collisions, track reconstruction for PbPb events is done in two iterations. The first iteration reconstructs tracks from signals ("hits") in the silicon pixel and strip detectors compatible with a trajectory of \(p_T > 0.9 \text{ GeV/c}\). The second iteration reconstructs tracks compatible with a trajectory of \(p_T > 0.2 \text{ GeV/c}\) using solely the pixel detector. In the final analysis, the first iteration tracks with \(p_T > 1.0 \text{ GeV/c}\) are combined with pixel-detector-only tracks with \(p_T < 2.4 \text{ GeV/c}\), after removing duplicates.

In this paper only tracks from primary charged particles are considered. For the XeXe tracks and the PbPb tracks with both silicon pixel and strip hits, the impact parameter significance of the tracks with respect to the primary vertex in both the beam direction (\(d_Z\)) and the transverse plane (\(d_0\)) must be less than 3 standard deviations, while the relative \(p_T\) uncertainty (\(\sigma_{p_T}/p_T\)) must be below 10%. In addition, each track is required to have at least 11 hits in the tracker, and the chi-square per degree of freedom, associated with fitting the track trajectory, normalized to the total number of layers with hits along the trajectory, \(\chi^2/\text{dof}/\text{layers}\), must be less then 0.15. For the PbPb pixel-only tracks, it was required that \(d_Z\) be less than 8 standard deviations and that \(\chi^2/\text{dof}/\text{layers} < 12\).

4 Analysis techniques

The analysis techniques used in this study are fully described in previous CMS publications. A two-particle correlation analysis, as discussed in Refs. \([25, 26]\), is performed for both the XeXe and PbPb data sets. In addition, scalar-product and multi-particle cumulant analyses, as described in Ref. \([27]\), are done for the XeXe data.

In the two-particle correlation analyses, a charged particle from one transverse momentum interval is used as a “trigger” particle, to be paired with all of the remaining charged particles from either the same or a different \(p_T\) interval, the “associated” particles. For a given trigger particle, the pairing is done in bins of pseudorapidity and azimuthal angle (\(\Delta \eta, \Delta \phi\)). A similar pairing between the particles randomly chosen from two different events is done to establish a background distribution. A Fourier analysis of the azimuthal correlation between the trigger and associated particles leads to \(V_n\) coefficients, where \(V_n(p_T^{\text{trig}}, p_T^{\text{assoc}}) = v_n\{\langle p_T^{\text{trig}} \rangle^2 \langle p_T^{\text{assoc}} \rangle^2\} \) if factorization is assumed. To avoid short-range, nonflow correlations, a pseudorapidity gap of |\(\Delta \eta\)| > 2 is required for the particle pairs.

The scalar-product event-plane measurements are based on recentered flow Q-vectors, defined as:

\[
\vec{Q}_n = \left( \sum_i w_i \cos (n\phi_i) - \frac{1}{M} \sum_i w_i \cos (n\phi_i) \right) \left( \sum_i w_i \sin (n\phi_i) - \frac{1}{M} \sum_i w_i \sin (n\phi_i) \right).
\]

Here, \(w_i\) is a weight for the \(i\)th particle emitted at azimuthal angle \(\phi_i\). The summations are
over the number of particles $M$ within a given (centrality, $\eta$ range, $p_T$ range) analysis bin for a given event. The averages indicated by the angular brackets are taken over all particles in all events within each analysis bin. These averages correspond to the recentering operation and are needed to minimize detector acceptance effects. If the $Q$-vectors are presented as the corresponding complex scalars, the flow coefficients are given by

$$v_n \{\text{SP}\} \equiv \frac{\langle Q_n Q_{nA}^* \rangle}{\langle Q_{nA} Q_{nB} \rangle \langle Q_{nB} Q_{nC} \rangle} \sqrt{\langle Q_{nA} Q_{nB} \rangle \langle Q_{nA} Q_{nC} \rangle \langle Q_{nB} Q_{nC} \rangle}.$$  

The particles of interest are used to obtain the $Q_n$ vector, with unit weighting ($w_i = 1$) in the sum. The subscripts $A$, $B$, and $C$ refer to three separate reference vectors established in different $\eta$ regions. The product of $Q_n$ with the $Q_{nA}$ reference vector correlates the particles of interest with particles detected in the HF calorimeter (region A). For the current measurement particles of interest with $-0.8 < \eta < 0.0$ ($0.0 < \eta < 0.8$) and within different $p_T$ ranges are correlated with HF particles in the range $3 < \eta < 5$ ($-5 < \eta < -3$). The products with $Q$-vectors $B$ and $C$ are used to correct for finite resolution effects. The $Q_{nC}$ vector corresponds to particles detected in the HF calorimeter opposite to that used to define the $Q_{nA}$ vector. The $Q_{nB}$ vector corresponds to particles measured in the tracker with $|\eta| < 0.5$. Since the $v_n(p_T)$ coefficients increase with $p_T$ up to $\approx 3\text{GeV}/c$, the choice of either $p_T$ or $E_T$ weighting results in a better event-plane resolution than with unit weighting. The $Q_{nA}$ and $Q_{nC}$ vectors use $E_T$ weighting, whereas the $Q_{nB}$ vector uses $p_T$ weighting [28].

The Q-cumulant method is used in this analysis to obtain the four- ($v_n(4)$), six- ($v_n(6)$), and eight- ($v_n(8)$) particle $n$th-order harmonic results by correlating unique combinations of 4, 6, and 8 particles within each event. The method uses a generic framework described in Ref. [29]. This framework allows for a track-by-track weighting to correct for the detector acceptance effects.

Results are presented in ranges of collision centrality. The centrality variable is defined as a fraction of the inelastic hadronic cross section, with 0% corresponding to full overlap of the two colliding nuclei. The event centrality is determined offline and is based on the total energy measured in calorimeters located in the forward pseudorapidity region $3 < |\eta| < 5$. The analysis is performed in eleven centrality classes, with intervals ranging from 0–5% to 60–70%. By comparing the XeXe and PbPb results in given centrality ranges, similar collision overlap geometries can be achieved, albeit with different numbers of participants.

5 Systematic uncertainties

Four different sources of systematic uncertainties are considered. To study the effect of the track selection on the final results, different track criteria are applied by varying the limits for the impact parameter significance from 2 to 5, and the relative $p_T$ uncertainty from 5% to 10%. These variations are found to have a 1% influence on $v_n$ results for peripheral collisions, increasing to 10% for the most central collisions at the lowest $p_T$ values. The effect of moving the primary vertex position along the beam axis is studied by comparing the results with events from the vertex position ranges $|z_{vtx}| < 3\text{cm}$ and $3 < |z_{vtx}| < 15\text{cm}$ to the default range of $|z_{vtx}| < 15\text{cm}$. A 1% systematic uncertainty is attributed to this source. The systematic uncertainty resulting from the XeXe centrality calibration is estimated by varying the event selection criteria until the efficiency changes by $\pm3\%$. This uncertainty is largest for the most peripheral centrality bin, where it reaches a value of 3%. To explore the sensitivity of the results to the MC simulations on which the efficiency determinations are based, analyses using the HYDJET
1.9 [30] event generator are done for generated tracks both before and after the detector effects are taken into account. The results for the two cases differ by about 2% for most centrality ranges, but the difference increases to 10% for the most central events and the lowest track transverse momenta, 0.3–0.4 GeV/c. The observed differences are included as a systematic uncertainty. The different uncertainty sources are independent and uncorrelated, therefore the total systematic uncertainty is obtained by combining the individual contributions in quadrature.

6 Results

Figure 1 shows the $v_2$ results, as a function of $p_T$ and in eleven centrality bins, as measured with the different techniques. The two- and multi-particle correlation results are averaged over the pseudorapidity range of $|\eta| < 2.4$, while the SP results are based on tracks with $|\eta| < 0.8$. The elliptic flow values extracted from two-particle correlations show the same pattern as with the multi-particle correlations, but with higher magnitudes. The difference in the results obtained from the two different methods can be largely ascribed to event-by-event fluctuations of the $v_2$ coefficient [20]. The $v_2$ magnitude increases with $p_T$, reaching a maximum value of 0.21 around 3–4 GeV/c in the 30–35% centrality range, and then slowly decreases. The maximum shifts to a lower $p_T$ value as the events become more peripheral. In the most peripheral events, the $v_2$ distribution becomes almost flat for $p_T > 3.0$ GeV/c. This may be a consequence of nonflow, di-jet correlations dominating the results as the system size becomes small.

![Figure 1: Elliptic-flow coefficients, $v_2$, based on different analysis techniques, as functions of transverse momentum and in bins of centrality, from the 5% most central (top left) to 60–70% centrality (bottom right). The results for the two-particle and multi-particle correlations correspond to the range $|\eta| < 2.4$, while the SP results are for $|\eta| < 0.8$. The bars and the shaded boxes represent statistical and systematic uncertainties, respectively.](image)

Figure 2 shows the $v_3$ values. The difference between the two- and four-particle results is even larger than for the $v_3$ values, exceeding a factor of two. For most centralities, the 4-particle
distributions have no clear peak value and their $p_T$ dependence is not as prominent as that obtained from the 2-particle and SP methods. This suggests a larger fluctuation component to triangular flow as compared to elliptic flow. The difference in amplitude would be qualitatively expected if the $v_3$ correlations were dominated by initial-state fluctuations [18]. The $v_3(2)(p_T)$ distribution has a similar shape as found for the $v_2(2)(p_T)$ distribution, but with smaller values that approach zero, or even become negative, at higher $p_T$ values in the most peripheral centrality ranges.

The $v_4$ results from the two-particle correlation and SP methods are presented in Fig. 3. The shape of the $v_4(p_T)$ distribution is similar to those for the other measured harmonics. All three harmonics, with $n = 2, 3,$ and 4, are found to have maxima at similar $p_T$ values, but with the $n = 3$ and $n = 4$ harmonics having a reduced centrality dependence as compared to the $n = 2$ harmonic. For all three harmonics, the SP values are systematically larger than the two-particle correlation results. While fluctuation effects are expected to affect both methods in a similar way, the methods measure flow in different pseudorapidity ranges, which might account for the observed difference. The similarity of the results suggests there is only a weak pseudorapidity dependence for all three harmonics.

The spectrum-weighted, single-particle anisotropy coefficients, using the two- and multi-particle correlation methods, are presented in Fig. 4. The $v_2$ coefficients show a strong centrality dependence with a maximum value in the 40–50% centrality bin. The $v_3$ and $v_4$ coefficients show less centrality dependence. Results based on multi-particle cumulants are below the $v_n(2)$ values, as expected. The predictions of the IP-GLASMA+MUSIC+UrQMD model are compared to the experimental $v_n(2)$ results. In this model, initial-state dynamics are described by impact parameter dependent flowing Glasma gluon fields [31]. The subsequent hydrodynamic evolution...

![Figure 2: Triangular-flow coefficients, $v_3$, based on the different analysis techniques, as functions of transverse momentum and in bins of centrality, from the 5% most central (top left) to 60–70% centrality (bottom right). The results for the two-particle and multi-particle correlations correspond to the range $|\eta| < 2.4$, while the SP results are for $|\eta| < 0.8$. The bars and the shaded boxes represent statistical and systematic uncertainties, respectively.](image-url)
is calculated with a MUSIC simulation [32], which is a relativistic (3+1)D model that includes shear viscosity (with a shear viscosity over entropy ratio $\eta/s = 0.16$) and a temperature-dependent bulk viscosity over entropy ratio $(\zeta/s(T))$ [33]. The simulation finally switches from a fluid-dynamic description to a transport description using the ultrarelativistic quantum molecular dynamics (UrQMD) model at the hadronization hypersurface [34]. The theoretical calculations are in good agreement with data for the $v_2$ coefficient, the calculation gives very slightly larger values than observed, with the difference increasing as the size of the nuclear overlap region decreases (i.e., increasing centrality percentage).

Figure 3 shows the ratios $v_2/6/v_2/4$, $v_2/4/v_2/2$, and $v_3/4/v_3/2$. Theoretical predictions from a hydrodynamic model [35] calculation that uses $T_0$ initial conditions [36] and from the IP-GLASMA+MUSIC+UrQMD model are compared to the experimental results. The former starts the hydrodynamic evolution at a time $\tau = 0.6$ fm/$c$ and has a shear viscosity to entropy ratio of $\eta/s = 0.047$. The $v_2/4/v_2/2$ ratio shows a strong centrality dependence, with the greatest deviation from unity, with a value of 0.625, corresponding to 5–10% central events. The $v_3/4/v_3/2$ and $v_2/6/v_2/4$ ratios show little, if any, centrality dependence. The $v_3/4/v_3/2$ has a value close to 0.55 for all centralities, indicating a strong influence of fluctuations on triangular flow [20]. The $v_2/6/v_2/4$ ratio is a few percent below unity and suggests the existence of higher-order corrections to a near-Gaussian distribution of the event-by-event flow fluctuations [37].

The IP-GLASMA+MUSIC+UrQMD and hydrodynamic models give comparable agreement with data for the flow harmonic ratios. Xenon is known to be a deformed nucleus with a quadrupole deformation of $\epsilon_2 = 0.15$ [38]. The hydrodynamic predictions are performed assuming both spherical and nominally deformed xenon nuclei. No significant difference is found with the two calculations. This suggests that the fluctuations are not sensitive to the small deformation
Figure 4: Centrality dependence of the spectrum-weighted $v_2$, $v_3$, and $v_4$ flow harmonics with $0.3 < p_T < 3.0 \text{ GeV/c}$. The $v_2$ results are shown for 2-, 4-, 6-, and 8-particle correlations (left panel). The $v_3$ results are shown for 2- and 4-particle correlations (middle panel), while the $v_4$ values are presented for two-particle correlations technique, only. The magenta line in each panel is the IP-Glasma+MUSIC+UrQMD prediction for $v_n \{2, |\eta| > 2\}$. The shaded boxes represent systematic uncertainties.

Figure 5: Centrality dependence of $v_2 \{4\} / v_2 \{2\}$, $v_2 \{6\} / v_2 \{4\}$ (left panel) and $v_3 \{4\} / v_3 \{2\}$ (right panel) ratios. The colored areas represent the theoretical predictions based on the IP-Glasma+MUSIC+UrQMD and the relativistic hydrodynamic model from Ref. [35] considering both spherical and deformed xenon nuclei, while the widths of the areas show the statistical uncertainties of the model. The $T_{\text{R\text{EnTo}}}$ calculation is done for the $p_T$ range $0.2 < p_T < 5.0 \text{ GeV/c}$.

The $v_2$ coefficients obtained by the two-particle correlations technique for XeXe collisions at $\sqrt{s_{\text{NN}}} = 5.44 \text{ TeV}$ are compared with corresponding PbPb data at 5.02 TeV as a function of transverse momentum in various centrality bins in Fig. 6. The $v_2$ values for the two systems show a similar dependence on $p_T$. However, the maximum value of the PbPb elliptic flow coefficient is...
found to be greater than the corresponding XeXe value except in the 0–5% centrality bin. Since the participant fluctuation of the initial geometry has a dominant contribution to the space anisotropy in the most central collisions, lower values of \( v_2 \) in that region are expected with a larger system size in PbPb. The \( v_3 \{2, |\Delta\eta| > 2\} \) coefficients for the two systems are compared in Fig. 7. The \( v_3 \) harmonic is entirely generated by initial participant fluctuations, so slightly larger values are expected in XeXe than in PbPb for central events (e.g., 0–30% centrality), as observed in the data. However, the \( v_3 \) harmonic has a larger sensitivity to transport coefficients (i.e., the shear viscosity) of the created medium, which tends to suppress the azimuthal anisotropy, especially for systems with a small size. This might explain the trend of \( v_3 \) where the system with the larger value is reversed in the 30–70% centrality range, with the larger PbPb system showing slightly higher \( v_3 \) values for more peripheral events. The \( v_4 \{2, |\Delta\eta| > 2\} \) coefficients in PbPb and XeXe collisions are shown in Fig. 8. Similar to the \( v_2 \) and \( v_3 \) harmonics, the ordering of the \( v_4 \) harmonic between the two systems is consistent with participant fluctuations having a dominant role in central collisions, and viscosity effects becoming more important for mid-central and peripheral collisions.

Since ideal hydrodynamics is scale invariant, the XeXe and PbPb results should have similar behavior [35]. For the same percentage centrality range, the interaction regions of the two colliding systems will have similar average shapes, but will have different size. For example, in the 30–40% centrality class, the number of participating nucleons is about 1.6 times higher for the PbPb collisions. However, initial-state fluctuations and viscosity corrections can cause scale invariance breaking. Fluctuations of the initial state are proportional to \( A^{-1/2} \), where \( A \) is the atomic mass, and, therefore, one can expect a larger fluctuation component for XeXe collisions than for PbPb collisions [39]. However, the influence of the localized fluctuations will decrease with increasing viscosity. The viscosity is thought to be proportional to \( A^{-1/3} \) [40] and is therefore also expected to be larger for XeXe collisions. Although the hydrodynamic model simulations do not suggest a large effect on the \( v_n \{4\}/v_n \{2\} \) and \( v_2 \{6\}/v_2 \{4\} \) ratios based on the Xe deformation, this deformation can influence the ratio of the XeXe and PbPb results. The quadrupole deformation of the colliding nuclei is expected to have the greatest influence for the XeXe \( v_2 \) values corresponding to the most central collisions [35].

In comparing the XeXe and PbPb results, it needs to be also noted that the XeXe results could be affected by an experimental bias in the centrality determination. For more peripheral events, multiplicity fluctuations in the forward region used to determine the event centrality can reduce the centrality resolution. Monte Carlo studies using the HYDJET event generator indicate this bias could be as large as 5% in the 50–60% centrality range and 10% in the 60–70% range for \( v_n \{2\} \). For \( v_n \{4\} \), the bias is less than 5% in the 60–70% centrality. For more central events, the bias is found to be negligible.

Figure 9 compares the spectrum-weighted \( v_2, v_3, \) and \( v_4 \) values with \( 0.3 < p_T < 3.0 \) GeV/c for the XeXe and PbPb systems. The largest difference between the two systems is found for the \( v_2 \) coefficients corresponding to the most central events, where the XeXe results are larger by a factor of about 1.3. For centralities above 10%, the PbPb results become higher and the ratio has only a weak centrality dependence. For the \( v_3 \) and \( v_4 \) coefficients, the ratio \( v_3 [\text{XeXe}] / v_3 [\text{PbPb}] \) decreases with centrality with an almost constant slope. The relativistic hydrodynamic model calculations of Ref. [35] are also shown in Fig. 9. Compared to calculations assuming a spherical Xe shape, including the xenon nuclear deformation in hydrodynamic models has little effect on the predicted flow characteristics over the centrality range 10–70%, as expected. For the most central 0–10% range, the \( v_2 [\text{XeXe}] / v_2 [\text{PbPb}] \) model ratio shows a greater sensitivity to the xenon nuclear deformation, with the calculation including deformation in better agreement with experiment. For all measured harmonics, the model values lie below the experimental
Figure 6: Comparison of the \( v_2 \) results measured with two-particle correlations from two different systems, XeXe collisions at \( \sqrt{s_{NN}} = 5.44 \) TeV and PbPb collisions at 5.02 TeV, shown as a function of \( p_T \) in eleven centrality bins. The bars (smaller than the marker size) and the shaded boxes represent statistical and systematic uncertainties, respectively.

The bars (smaller than the marker size) and the shaded boxes represent statistical and systematic uncertainties, respectively.
Figure 8: Comparison of the $v_4$ results measured with two-particle correlations from two different systems, XeXe collisions at $\sqrt{s_{NN}} = 5.44$ TeV and PbPb collisions at 5.02 TeV, shown as a function of $p_T$ in eleven centrality bins. The bars and the shaded boxes represent statistical and systematic uncertainties, respectively.

results, with the greatest difference found for the $v_4$ coefficients.

Figure 9: Centrality dependence of the spectrum-weighted $v_2$, $v_3$, and $v_4$ harmonic coefficients from two-particle correlations method for $0.3 < p_T < 3.0$ GeV/c for XeXe collisions at $\sqrt{s_{NN}} = 5.44$ TeV and PbPb collisions at 5.02 TeV. The lower panels show the ratio of the results for the two systems. The bars and the shaded boxes represent statistical and systematic uncertainties, respectively. Theoretical predictions from Ref. [35] are compared to the data (colored area). The model calculation is done for the $p_T$ range $0.2 < p_T < 5.0$ GeV/c.

Figure 10 shows the $p_T$ dependent ratios of XeXe and PbPb harmonic coefficients. The ratios
reach a maximum value between 1 and 2 GeV/c, within the current uncertainties, and then decrease up to $p_T \sim 6$ GeV/c, at which point they start to increase again. The increasing trend above 6 GeV/c, which is most pronounced for the $v_2$ coefficient, may be a consequence of back-to-back dijet correlations that can not be fully eliminated with the $|\Delta \eta| > 2$ requirement.

![Figure 10: Ratios of the $v_2$, $v_3$, and $v_4$ harmonic coefficients from two-particle correlations in XeXe and PbPb collisions as functions of $p_T$ in eleven centrality bins. The bars and the shaded boxes represent statistical and systematic uncertainties, respectively.](image)

7 Summary

In this paper, the $v_2$, $v_3$, and $v_4$ azimuthal flow harmonics are shown for xenon-xenon (XeXe) collisions at a center-of-mass energy per nucleon pair of $\sqrt{s_{NN}} = 5.44$ TeV based on data obtained with the CMS detector. Three analysis techniques with different sensitivities to flow fluctuations, including two-particle correlations, the scalar-product method, and the multiparticle cumulant method, are used to explore the event-by-event fluctuations. The harmonic coefficients are compared to those found with lead-lead (PbPb) collisions at $\sqrt{s_{NN}} = 5.02$ TeV to explore the effect of the system size. The magnitude of the $v_2$ coefficients for XeXe collisions are larger than those found in PbPb collisions for the most central collisions. This is attributed to a larger fluctuation component in the lighter colliding system. In more peripheral events, the PbPb $v_n$ coefficients are consistently larger than those found for XeXe collisions. This behavior is qualitatively consistent with expectations from hydrodynamic models. A clear ordering $v_2 \{2\} > v_2 \{4\} \approx v_2 \{6\} \approx v_2 \{8\}$ is observed for XeXe collisions, with $v_2 \{6\}$ and $v_2 \{4\}$ values differing by 2–3%. The $v_3 \{4\}/v_3 \{2\}$ ratio is found to be significantly smaller than the $v_2 \{4\}/v_2 \{2\}$ ratio, suggesting a dominant fluctuation component for the $v_3$ harmonic. Hydrodynamic models that consider the xenon nuclear deformation are able to better describe the $v_2 [\text{XeXe}] / v_2 [\text{PbPb}]$ ratio in central collisions than those assuming a spherical Xe shape, although the deformation appears to have little effect on the fluctuation-sensitive ratio of the cumulant orders. These measurements provide new tests of hydrodynamic models and help to constrain hydrodynamic descriptions of the nuclear collisions.
Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RPF (Cyprus); SENESCYT (Ecuador); MoER, ERC IUT, and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); NKFIA (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MES (Monterey); MIEE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS, RFBR, and NRC KI (Russia); MESTD (Serbia); SEIDI, CPAN, PCTI, and FEDER (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR, and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU and SFFR (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

Vanderbilt University, Nashville, USA

University of Virginia, Charlottesville, USA
M.W. Arenton, P. Barria, B. Cox, R. Hirosky, M. Joyce, A. Ledovskoy, H. Li, C. Neu, T. Sinthuprasith, Y. Wang, E. Wolfe, F. Xia

Wayne State University, Detroit, USA

University of Wisconsin - Madison, Madison, WI, USA

†: Deceased
1: Also at Vienna University of Technology, Vienna, Austria
2: Also at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France
3: Also at Universidade Estadual de Campinas, Campinas, Brazil
4: Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil
5: Also at Université Libre de Bruxelles, Bruxelles, Belgium
6: Also at University of Chinese Academy of Sciences, Beijing, China
7: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia
8: Also at Joint Institute for Nuclear Research, Dubna, Russia
9: Now at Cairo University, Cairo, Egypt
10: Also at Fayoum University, El-Fayoum, Egypt
11: Now at British University in Egypt, Cairo, Egypt
12: Also at Department of Physics, King Abdulaziz University, Jeddah, Saudi Arabia
13: Also at Université de Haute Alsace, Mulhouse, France
14: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
15: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
16: Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany
17: Also at University of Hamburg, Hamburg, Germany
18: Also at Brandenburg University of Technology, Cottbus, Germany
19: Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary
20: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
21: Also at Institute of Physics, University of Debrecen, Debrecen, Hungary
22: Also at Indian Institute of Technology Bhubaneswar, Bhubaneswar, India
23: Also at Institute of Physics, Bhubaneswar, India
24: Also at Shoolini University, Solan, India
25: Also at University of Visva-Bharati, Santiniketan, India
26: Also at Isfahan University of Technology, Isfahan, Iran
27: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
28: Also at Università degli Studi di Siena, Siena, Italy
29: Also at Kyunghee University, Seoul, Korea
30: Also at International Islamic University of Malaysia, Kuala Lumpur, Malaysia
31: Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia
32: Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico
33: Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland
34: Also at Institute for Nuclear Research, Moscow, Russia
35: Now at National Research Nuclear University ‘Moscow Engineering Physics Institute’ (MEPhI), Moscow, Russia
36: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
37: Also at University of Florida, Gainesville, USA
38: Also at P.N. Lebedev Physical Institute, Moscow, Russia
39: Also at INFN Sezione di Padova a, Università di Padova b, Università di Trento (Trento) c, Padova, Italy
40: Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia
41: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
42: Also at INFN Sezione di Pavia a, Università di Pavia b, Pavia, Italy
43: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
44: Also at Scuola Normale e Sezione dell’INFN, Pisa, Italy
45: Also at National and Kapodistrian University of Athens, Athens, Greece
46: Also at Riga Technical University, Riga, Latvia
47: Also at Universität Zürich, Zurich, Switzerland
48: Also at Stefan Meyer Institute for Subatomic Physics (SMI), Vienna, Austria
49: Also at Istanbul Aydin University, Istanbul, Turkey
50: Also at Mersin University, Mersin, Turkey
51: Also at Piri Reis University, Istanbul, Turkey
52: Also at Adiyaman University, Adiyaman, Turkey
53: Also at Ozyegin University, Istanbul, Turkey
54: Also at Izmir Institute of Technology, Izmir, Turkey
55: Also at Marmara University, Istanbul, Turkey
56: Also at Kafkas University, Kars, Turkey
57: Also at Istanbul University, Faculty of Science, Istanbul, Turkey
58: Also at Istanbul Bilgi University, Istanbul, Turkey
59: Also at Hacettepe University, Ankara, Turkey
60: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
61: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
62: Also at Monash University, Faculty of Science, Clayton, Australia
63: Also at Bethel University, St. Paul, USA
64: Also at Karamanoğlu Mehmetbey University, Karaman, Turkey
65: Also at Utah Valley University, Orem, USA
66: Also at Purdue University, West Lafayette, USA
67: Also at Beykent University, Istanbul, Turkey
68: Also at Bingol University, Bingol, Turkey
69: Also at Sinop University, Sinop, Turkey
70: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
71: Also at Texas A&M University at Qatar, Doha, Qatar
72: Also at Kyungpook National University, Daegu, Korea
