SEARCH FOR HIGGS BOSON PAIR PRODUCTION WITH THE ATLAS DETECTOR

John C.S. Myers*
University of Oregon

E-mail: jmyers@cern.ch

The Standard Model (SM) very successfully describes experimental observations, but is known to be an incomplete theory. Measurements of SM parameters and checks of its self consistency are important to improve our understanding of nature. An important parameter to understand electroweak symmetry breaking is the Higgs boson self-coupling, which can be accessed in Higgs boson pair production. These studies are already important now to search for potential effects of physics beyond the SM as well as to prepare for the analysis of the full dataset of the HL-LHC. This poster will present the latest results on the Higgs pair production with the ATLAS detector with a focus on the 4b final state.

Higgs Boson Pair Production

John C.S. Myers

Figure 1: The observed and expected 95% CL upper limits on the production cross section times branching ratio for the narrow width scalar approximation for the a) $b\bar{b}b\bar{b}$[1], b) $\gamma\gamma b\bar{b}$[2], c) $\gamma\gamma WW^*$[3], d) $b\bar{b}\tau^+\tau^-$[4] final states.

1. Standard Model Cross Section Limit

Figure 2: The observed and expected 95% CL upper limits on the Standard Model Di-Higgs production cross section normalized by the Standard Model Prediction [5].

2. Summary and Conclusion

No significant excesses reported for BSM Resonant Di-Higgs production for ATLAS during Run 2 at this point. With the largest deviation, in the $b\bar{b}b\bar{b}$, at a mass of 280 GeV with a global significance of 2.8 $\sigma$. Limits are set for resonant production in the $b\bar{b}b\bar{b}$, $\gamma\gamma b\bar{b}$, $\gamma\gamma WW^*$, and $b\bar{b}\tau^+\tau^-$ final states. A 95% CL upper limit was placed on the non-resonant production corresponding to 12.7 times the SM expectation from the $b\bar{b}\tau^+\tau^-$ final state.
