Abstract

The Brill–Hartle gravitational geon construct as a spherical shell of small amplitude, high frequency gravitational waves is reviewed and critically analyzed. The Regge–Wheeler formalism is used to represent gravitational wave perturbations of the spherical background as a superposition of tensor spherical harmonics and an attempt is made to build a non–singular solution to meet the requirements of a gravitational geon. High–frequency waves are seen to be a necessary condition for the geon and the field equations are decomposed accordingly. It is shown that this leads to the impossibility of forming a spherical gravitational geon. The attempted constructs of gravitational and electromagnetic geons are contrasted. The spherical shell in the proposed Brill–Hartle geon does not meet the regularity conditions required for a non–singular source and hence cannot be regarded as an adequate geon construct. Since it is the high frequency attribute which is the essential cause of the geon non–viability, it is argued that a geon with less symmetry is an unlikely prospect. The broader implications of the result are discussed with particular reference to the problem of gravitational energy.

To appear in Int. J. Mod. Phys. D
1 Introduction

Forty years ago, the geon concept was introduced [1]: zero rest mass field concentrations held together for long periods of time by their gravitational attraction. Such constructs were motivated by studies of the motion of bodies in general relativity. More recent interest arises from the study of the entropy of radiation [2] and from the analogy between electromagnetic geons and quark stars [3]. Electromagnetic, neutrino and mixed type geons were studied [1], [4]–[9] and it was suggested that it should be possible to construct a geon from gravitational waves [10]. Brill and Hartle [11] (henceforth referred to as BH) attempted the construction of a gravitational geon model in detail. Later papers ([12, 13] – see also [14]) assumed the correctness of the BH model. In their approach, BH considered a strongly curved static or quasi-static “background geometry” $\gamma_{\mu\nu}$ on top of which a small ripple $h_{\mu\nu}$ resided, satisfying a linear wave equation. The wave frequency was assumed to be so high as to create a sufficiently large effective energy density which served as the source of the background $\gamma_{\mu\nu}$, taken to be spherically symmetric on a time average. For their analysis, they took the Regge–Wheeler [10] (henceforth referred to as RW) decomposition of $h_{\mu\nu}$ in a spherical background in terms of waves characterized by the usual quantum numbers $l, m$ related to the angular momentum operators, and by the frequency $\omega$. They claimed to have found a solution with a flat–space spherical interior, a Schwarzschild exterior and a thin shell separation meant to be created by high frequency gravitational waves. With the mass $M$ identified from the exterior metric, there would follow an unambiguous realization of the gravitational geon as described above.

To be complete, however, two conditions must be satisfied. Firstly, the gravitational geon must be a non-singular solution of the Einstein equations in vacuum. Any singularities present would indicate the presence of non-gravitational sources $T_{\mu\nu}$ compactified into points, curves or surfaces, negating the desired non-singular purely field structure. Secondly, the consistency of the solution must be demonstrated, namely that the background $\gamma_{\mu\nu}$ is consistent with the time–averaged effective density constructed from $h_{\mu\nu}$ as source in the region of non–vanishing $h_{\mu\nu}$. Regarding the first condition, it is straightforward to show that the junction conditions for regularity are not satisfied by the BH solution and hence as it stands, cannot be taken as singularity-free. With the first condition violated, there is no basis for proceeding with a consideration of the second.

One might reasonably argue that while the given structure is inadequate as it stands, an expansion of the shell region into one of finite extent would reveal a well–posed geon solution with both regularity and consistency. Our analysis is sufficiently general to include this geometry in which the gravitational field decays sufficiently rapidly at spatial
infinity, and to consider also the possibility of geons “leaking” radiation to the exterior. Odd high frequency modes in the RW formalism were analyzed in conjunction with a static and a time-dependent spherically symmetric background metric $\gamma_{\mu\nu}$. It was found that the Einstein equations do not allow a solution with the required characteristics and hence a spherical gravitational geon cannot exist. While the even mode case or a case with a more general geometry than spherical was not yet analyzed, it would be unexpected that such a geon could be found when the most primitive case is excluded. Moreover, the key factor which leads to the non-existence of the spherical geon is not the spatial symmetry but rather the high frequency. This fortifies the expectation that the result is general.

A brief preliminary description of this work was published in [15]. The present paper provides details of the calculations and an expanded study of the gravitational geon problem. It also goes beyond the insufficient generality that was analyzed in the earlier paper$^1$. In Sec. 2, we review the basic mathematical formalism for the construction of gravitational geons. This is used in Sec. 3 to analyze the proposed BH solution. In Sec. 4, we attempt the construction of a non-singular solution for a gravitational geon with spherical symmetry and contrast the results with the electromagnetic case. It is demonstrated that the Einstein equations do not permit the realization of the gravitational geon. In Sec. 5, the results of the previous section are discussed and the viability of the proposed electromagnetic geon is critically examined. We conclude with a discussion of the potential ramifications of these results with reference to the problem of gravitational energy.

## 2 Gravitational geons

We consider the spacetime metric given by$^2$

$$g_{\mu\nu} = \gamma_{\mu\nu} + h_{\mu\nu},$$  \hspace{1cm} (2.1)

where we assume that $g_{\mu\nu}$ is asymptotically flat, that $\gamma_{\mu\nu}$ is a static, spherically symmetric, asymptotically flat metric and $h_{\mu\nu}$ are small perturbations ($|h_{\mu\nu}| << 1$) representing

$^1$We are grateful to to Dr. Paul Anderson for very helpful discussions in this regard.

$^2$The metric signature is $- + + +$. We use units in which $G = c = 1$. Greek indices run from 0 to 3 and Latin indices run from 1 to 3 (apart from Appendix B, where they assume the values 0, 2 and 3). A comma and a semicolon denote, respectively, ordinary and covariant differentiation with respect to the background metric. The Ricci tensor is given by $R_{\mu\nu} = \Gamma^\sigma_{\mu\nu,\sigma} - \Gamma^\sigma_{\mu\nu,\sigma} + \Gamma^\sigma_{\rho\nu}\Gamma^\rho_{\mu\sigma} - \Gamma^\sigma_{\rho\nu}\Gamma^\rho_{\mu\sigma}$. 

2
gravitational waves. In a system of Schwarzschild-like coordinates \( \{x^\alpha\} = \{t, r, \theta, \varphi\} \), the background metric is given by

\[
(\gamma_{\mu\nu}) = \text{diag}\left(-e^\nu, e^\lambda, r^2, r^2 \sin^2 \theta\right),
\]

where \( \lambda = \lambda(r) \), \( \nu = \nu(r) \) (2.3)

and

\[
h_{\mu\nu} = h_{\mu\nu}(t, r, \theta, \varphi).
\]

Following BH, we represent the most general gravitational wave perturbation \( h_{\mu\nu} \) of the spherical background as a superposition of tensor spherical harmonics:

\[
h_{\mu\nu} = \sum_{l=0}^{+\infty} \sum_{m=-l}^{+l} \int_0^\infty d\omega h_{\mu\nu}^{(l\omega)}(r, \theta, \varphi) e^{i\omega t} + \text{c.c.}
\]

This is justified by the fact that the dynamics of the gravitational waves in the present context are governed by the linearized Einstein equations around the background \( \gamma_{\mu\nu} \) and therefore a superposition principle holds. Due to linearity, we can restrict ourselves to a study of the evolution of the single tensor spherical modes. For ease of comparison with the BH paper, we will use the RW set of tensor spherical harmonics ([10], [16]–[18]; see [19] for a review and for relations with other sets of tensor spherical harmonics). An “even mode” (also called “polar mode” by other authors [20]) in the RW formalism is factorized as the product of functions dependent only on time, radius, and angles respectively. The angular part is determined by the numbers \( l \) and \( m \) related to the usual scalar spherical harmonics. The even modes have the form

\[
h_{\mu\nu}^{(\text{even})}(t, r, \theta, \varphi) = \begin{pmatrix}
-e^\nu H_0(r) & H_1(r) & 0 & 0 \\
H_1(r) & e^\lambda H_2(r) & 0 & 0 \\
0 & 0 & r^2 K(r) & 0 \\
0 & 0 & 0 & r^2 K(r) \sin^2 \theta
\end{pmatrix} Y^{lm} e^{-i\omega t},
\]

(2.6)
where $Y_{lm}(\theta, \varphi)$ are the usual spherical harmonics\footnote{Strictly speaking, the radial functions in Eqs. (2.6) and (2.7) depend on $\omega, l$ and $m$ and should be labelled accordingly. However, this would result in a cumbersome notation that is preferably avoided.}. These modes have parity $(-)^l$. The “odd modes” (in the RW terminology – also called “axial modes”) are given by

$$
\begin{align*}
\hat{h}_{\mu\nu}^{(\text{odd})}(t, r, \theta, \varphi) = & \\
= & \begin{pmatrix}
0 & 0 & -h_0(r) (\sin \theta)^{-1} \frac{\partial}{\partial \varphi} Y_{lm} & h_0(r) \sin \theta \frac{\partial}{\partial \theta} Y_{lm} \\
0 & 0 & -h_1(r) (\sin \theta)^{-1} \frac{\partial}{\partial \varphi} Y_{lm} & h_1(r) \sin \theta \frac{\partial}{\partial \theta} Y_{lm} \\
\text{Sym} & \text{Sym} & 0 & 0 \\
\text{Sym} & \text{Sym} & 0 & 0
\end{pmatrix} e^{-i\omega t}
\end{align*}

(2.7)

and have parity $(-)^{l+1}$. We will consider the case of odd modes only because of the relative ease in computations. It is unlikely that the even modes would produce a contrary result although it would be useful if a follow-up calculation were to be performed to verify this conjecture.

A gravitational geon is defined as a bounded configuration of gravitational waves whose gravity is sufficiently strong to keep them confined on a time scale long compared to the characteristic composing wave period. It is required that no matter or fields other than the gravitational field be present. Although one may consider the possibility of strong gravitational waves, and the definition of gravitational geon allows for this possibility, in this paper we will restrict ourselves to the case in which the amplitude of gravitational waves is small. This permits us to apply the linearized Einstein theory to the propagation of each single wave in the background created by the average action of all the waves composing the geon. Furthermore, it is required that the configuration represented by the metric $\gamma_{\mu\nu}$ be stable over a time scale much larger than the typical period of its gravitational wave constituents, and that the gravitational field becomes asymptotically flat at spatial infinity. Gravitational geons were introduced on the basis of the analogy with electromagnetic and neutrino geons in the RW paper and were studied in greater detail by BH. Wheeler’s method of building an electromagnetic geon was to replace the details of the electromagnetic field by the time average of the components of the electromagnetic stress–energy tensor. Upon averaging over many modes of oscillation of the electromagnetic field, one obtains a stress-energy tensor, and as a consequence, a gravitational field and metric which are spherically symmetric. Any given mode of oscillation is taken to propagate in the spherically symmetric gravitational field created by the rest of the radiation. The attempt to build a geon resembles the construction,
in other fields of physics, of a system with many (almost) identical components, each of which introduces a negligible perturbation in the dynamics of the whole system and has an evolution governed by the averaged action of all the other components. An example of such a system in Newtonian theory is a galaxy described by the potential created by the mass distribution of many stars (here we neglect dark matter, and the fact that a potential-density pair usually describes only a single component of a galaxy, and is adequate only for certain types of galaxies [22]). Each star gives a very small contribution to this potential and its orbit is determined by the global galactic potential.

Consistent with this idea, it is required that

\[ \gamma_{\mu \nu} = \langle g_{\mu \nu} \rangle . \]

We also have

\[ \langle h_{\mu \nu} \rangle = \left\langle \frac{\partial h_{\mu \nu}}{\partial x^\alpha} \right\rangle = \left\langle \frac{\partial^2 h_{\mu \nu}}{\partial x^\alpha \partial x^\beta} \right\rangle = 0 , \]

where \( \langle \, \rangle \) denotes an average over a time that is much longer than the typical gravitational wave wavelength \( \lambda \) (“Brill-Hartle average”). A mathematically rigorous treatment of this concept is contained in the paper by MacCallum and Taub [23]. This idea has proved very valuable and the averaging process has been used by many authors after BH, and is well defined only if it is assumed that the typical wavelength \( \lambda \) is much smaller than the space and time scale of variation \( L \) of the background metric \( \gamma_{\mu \nu} \) (high frequency approximation) [21]:

\[ \epsilon \equiv \frac{\lambda}{L} << 1 . \]

This assumption provides us with a smallness parameter \( \epsilon \) to be used as an expansion parameter. Following [21], we measure times and lengths in units of \( L \) so that \( \lambda = \epsilon \). We have also

\[ h_{\mu \nu} = O(\epsilon) , \]

\[ \omega = \frac{2\pi}{\lambda} = O\left( \frac{1}{\epsilon} \right) , \]

The term “typical gravitational wavelength” \( \lambda \) may be source of confusion to some readers. Since we are decomposing the general wave form into an infinite set of Regge-Wheeler modes, one may think that \( \lambda \) represents the wavelength of each mode, and that Eq. (2.10) is only valid if the geon was composed of one and only one mode. However, when one is analyzing a general wave form, it is justifiable to assign a single parameter describing the scale of variation of the wave form. In the present context, \( \lambda \) is the scale over which the wave form varies. Equation (2.10) is easily derived from Eq. (2.23) if one keeps in mind that \( h_{\mu \nu, \alpha} \sim \epsilon/\lambda \) etc. (see [24]) and that \( \lambda \) represents the scale of variation of \( h_{\mu \nu} \).
In our notation, $O(1) = O(e^0)$. Equation (2.11) is derived in [21, 24, 25]. It is to be noted that, in the most general case of high frequency gravitational waves on a curved spacetime, two smallness parameters are involved: the dimensionless amplitude of the waves and the ratio $\lambda/L$. These two parameters coincide in the specific case under consideration, in which the only source of the background curvature are the gravitational waves. One can conceive of situations in which more than one parameter arises from the high frequency approximation, and these cases have been considered in the literature (see e.g. [27]). However, in these situations, gravitational waves are not the only source of curvature. When gravitational waves are the only source of curvature, as in the gravitational geon, these multiple parameters reduce to the single parameter $\epsilon$. Equation (2.13) implies that the quantum numbers $l$ and $m$ are of order $O(1/\epsilon)$.

The Ricci tensor can be expanded in the form [11, 21]

$$ R_{\alpha\beta}(g) = R_{\alpha\beta}^{(0)}(\gamma) + R_{\alpha\beta}^{(1)}(\gamma, h) + R_{\alpha\beta}^{(2)}(\gamma, h) + \cdots, $$

where ([11, 21] and references therein)

$$ R_{\alpha\beta}^{(1)} = \frac{1}{2} \gamma^{\rho\tau} \left( h_{\rho\tau;\alpha\beta} + h_{\alpha\beta;\rho\tau} - h_{\tau\alpha;\beta\rho} - h_{\tau\beta;\alpha\rho} \right), $$

$$ R_{\alpha\beta}^{(2)} = -\frac{1}{2} \left[ \frac{\gamma^{\rho\tau}}{2} h_{\rho\tau;\alpha\beta} + h^{\rho\tau} (h_{\tau\rho;\alpha\beta} + h_{\alpha\beta;\rho\tau} - h_{\tau\alpha;\beta\rho} - h_{\tau\beta;\alpha\rho}) + h_{\beta}^{\tau\alpha} (h_{\tau\alpha;\beta} - h_{\alpha\beta;\tau}) - \left( h_{\beta;\rho} - \frac{h_{\beta}}{2} \right) (h_{\tau\alpha;\beta} + h_{\tau\beta;\alpha} - h_{\alpha\beta;\tau}) \right], $$

and $h \equiv h^{\alpha}_{\alpha}$. The term $R_{\alpha\beta}^{(0)}(\gamma)$ is the Ricci tensor of the background metric $\gamma_{\mu\nu}$, whereas $R_{\alpha\beta}^{(1)}$ and $R_{\alpha\beta}^{(2)}$ are, respectively, the parts of the Ricci tensor linear and quadratic in $h_{\mu\nu}$ and their derivatives. In the absence of high frequency waves (or on a flat background), $h_{\mu\nu}$ and their derivatives are all of order $O(\epsilon)$. In this case the superscripts on the expansion terms of Eq. (2.15) also indicate its order in powers of $\epsilon$. However, in the high frequency approximation it is clear that $R_{\mu\nu}^{(1)}$ contains terms of order $O(1/\epsilon)$ and $O(1)$ as
well as $O(\epsilon)$ [21]. Similarly, $R^{(2)}_{\mu\nu}$ is comprised of terms of order $O(1)$, $O(\epsilon)$, etc. Solving the vacuum field equations

$$R_{\mu\nu}(g) = 0 \tag{2.18}$$

consistently to any order of approximation requires that we set each order in the expansion parameter $\epsilon$ equal to zero. We express Eqs. (2.16) and (2.17) as

$$R^{(1)}_{\mu\nu}(\gamma, h) = R^{(1)}_{\mu\nu} [\epsilon^{-1}] + R^{(1)}_{\mu\nu} [\epsilon^0] + \cdots, \tag{2.19}$$

$$R^{(2)}_{\mu\nu}(\gamma, h) = R^{(2)}_{\mu\nu} [\epsilon^0] + R^{(2)}_{\mu\nu} [\epsilon] + \cdots, \tag{2.20}$$

where $R^{(k)}_{\mu\nu} [\epsilon^n]$ denotes the term of order $O(\epsilon^n)$ in $R^{(k)}_{\mu\nu}$. The first order approximation is thus

$$R^{(1)}_{\mu\nu} [\epsilon^{-1}] = 0. \tag{2.21}$$

The second order approximation requires that terms of order $O(1)$ be set equal to zero. The field equations to this order are

$$R^{(0)}_{\mu\nu}(\gamma) + R^{(1)}_{\mu\nu} [\epsilon^0] + R^{(2)}_{\mu\nu} [\epsilon^0] = 0. \tag{2.22}$$

Performing the Brill–Hartle average on Eq. (2.22), one obtains

$$R^{(0)}_{\mu\nu} (\gamma) = - \langle R^{(2)}_{\mu\nu} [\epsilon^0] \rangle. \tag{2.23}$$

Note that from Eq. (2.9)

$$\langle R^{(1)}_{\mu\nu} [\epsilon^{-1}] \rangle = \langle R^{(1)}_{\mu\nu} [\epsilon^0] \rangle = \cdots = 0 \tag{2.24}$$

and hence

$$\langle R^{(1)}_{\mu\nu} (\gamma, h) \rangle = 0. \tag{2.25}$$

In Eq. (2.23) the part of the Ricci tensor quadratic in $h_{\mu\nu}$ and their derivatives has been taken to the right hand side and is seen as an effective source term due to the gravitational waves. It is important to note that Eq. (2.23) has the potential to lead to the description of a gravitational geon only by virtue of the high frequency approximation. Under the assumption that gravitational waves are weak but not of high frequency, Eqs. (2.12)–(2.14) would not hold and the two terms in Eq. (2.23) would have different orders. $R^{(2)}_{\alpha\beta} = O(\epsilon^2)$ could never balance $R^{(0)}_{\alpha\beta}(\gamma) = O(1)$ in this equation. This would prevent a priori the construction of a gravitational geon. This point can be understood physically by noting that the effective energy density associated with gravitational waves...
with amplitude $h < 1 \ll 1$ and frequency $\omega$ is roughly proportional to $(h\omega)^2$. This quantity can be of order unity only if $\omega \sim 1/h \gg 1$. Therefore, it is clear that the high frequency approximation is a necessary condition for geon construction in the present context.

We shall designate as the “geon problem”, the problem of finding a solution $(\gamma_{\mu\nu}, h_{\mu\nu})$ to the Einstein equations (2.21), (2.22) and (2.23) with the above mentioned properties and satisfying the boundary conditions describing asymptotic flatness

$$h_{\mu\nu} \to 0 \quad \text{as} \quad r \to +\infty.$$  

(2.26)

3 The BH analysis

To the authors’ knowledge the only explicit attempt at gravitational geon construction was that of BH. In this Section we review their pioneering approach to the problem and critically analyze their work.

We follow BH in expressing the gravitational wave perturbations in terms of RW tensor spherical harmonics. For the sake of simplicity, as done by BH, we restrict ourselves to the case of odd modes with zero angular momentum along the $z$-axis (i.e. $m = 0$). The last assumption eliminates the $\varphi$-dependence from the $h_{\mu\nu}$ functions and considerably simplifies the Einstein equations. This can be seen from Eq. (2.7) and from the well-known form of the spherical harmonics that we present in Eqs. (3.4), (3.5) below. Thus, the metric perturbations are

$$h_{\mu\nu}(t, r, \theta) = R_{\mu\nu}(r) \Theta^l(\theta) e^{-i\omega t},$$  

(3.1)

where

$$R_{\mu\nu}(r) = h_0(r) \left( \delta^{\mu}_\theta \delta^\nu_\varphi + \delta^{\mu}_\varphi \delta^\nu_\theta \right) + h_1(r) \left( \delta^{1}_\theta \delta^\nu_\varphi + \delta^{1}_\varphi \delta^\nu_\theta \right),$$  

(3.2)

$$\Theta^l(\theta) = \sin \theta \frac{dY_{l0}}{d\theta} = C_{l0} \sin \theta \frac{dP_l(\cos \theta)}{d\theta}.$$  

(3.3)

Here we use the expression of the spherical harmonics

$$Y^{lm}(\theta, \varphi) = C^{lm} e^{im\varphi} P^m_l(\cos \theta) \quad (m \geq 0),$$  

(3.4)

For ease of comparison with the BH paper, we use a complex exponential to describe the time-dependence of the metric perturbations in Eq. (3.1). This notation is adequate as long as linear quantities in $h_{\mu\nu}$ and their derivatives are considered, but clearly it is incorrect when the part of the Ricci tensor quadratic in $h_{\mu\nu}$ and their derivatives enters the discussion. For future reference, we use a function of $\cos(\omega t)$ and $\sin(\omega t)$ instead of a complex exponential in our calculations of Sec. 4.
\[ Y^{lm}(\theta, \varphi) = (-1)^m \left( Y^{m0} \right)^* \quad (m < 0), \]  

(3.5)

where \( C^{lm} \) are normalization constants. Here * denotes complex conjugation and \( P^{lm}(x) \) are the associated Legendre polynomials (which can be expressed in terms of the Legendre polynomials \( P^l(x) \)). Using the relation \( P^{00}(x) = P^l(x) \) we obtain

\[ Y^{00}(\theta) = C^{00} P^l(\cos \theta), \]  

(3.6)

from which Eq. (3.3) follows. 

One can now insert the form (3.1)–(3.3) of the metric perturbations into the Einstein equations (2.18), obtaining equations for the unknown functions \( h_0(r) \) and \( h_1(r) \). Simultaneously solving Eqs. (2.21) and (2.23) for a pair \( (\gamma_{\mu\nu}, h_{\mu\nu}) \) then provides a solution to the geon problem.

The correct order of magnitude of the various terms in the Einstein equations is determined by Eqs. (2.11)–(2.14). The correct order of magnitude decomposition of the Einstein equations is absent in [11]. While the high frequency approximation was assumed in [11], it was not incorporated into the calculations. As a result, the authors did not obtain the two different orders \( O(1/\epsilon) \) and \( O(1) \) in the Einstein equations, using a parameter \( \epsilon \) arising from the high frequency approximation. This is evident from the fact that their final equations (10a)–(10c) and (14) contain terms of different orders in the high frequency limit. In the remaining part of this Section we will show how the BH results can be reproduced and we will comment on their proposed geon model.

The BH equations can only be reproduced in the absence of high frequency waves. In terms of a parameter \( \epsilon \) related to the weakness of the gravitational waves, Eqs. (2.11)–(2.14) must be replaced by

\[ O(h_{\mu\nu}) = O\left( \frac{\partial h_{\mu\nu}}{\partial x^\alpha} \right) = O\left( \frac{\partial^2 h_{\mu\nu}}{\partial x^\alpha \partial x^\beta} \right) = O(\epsilon) \quad \alpha, \beta = 0, \ldots, 3. \]  

(3.7)

As a consequence of these equations, the Ricci tensor has the form given by Eq. (2.15), where \( R^{(0)}_{\mu\nu} = O(1) \), \( R^{(1)}_{\mu\nu} = O(\epsilon) \) and \( R^{(2)}_{\mu\nu} = O(\epsilon^2) \). To order \( O(1) \) the Einstein equations give the well-known equations for a spherically symmetric, static background

\( ^6\text{Note a misprint in the second of the equations (8) in [11], corresponding to our Eq. (3.2). Also to be noted is an inconsistency in the notation therein: the form (3.1)–(3.3) for the metric perturbations is assumed in [11], but the number } m \text{ in the definition of the function } \Theta^{LM} \text{ corresponding to our } \Theta^l \text{ is retained. This is inappropriate since it is clear from Eqs. (8) and (9) in [11] that the intention was to set } m = 0. \text{ Otherwise, the function } \Theta^{LM} \text{ would depend on both } \theta \text{ and } \varphi, \text{ which is not the case, and the Einstein equations would be much more complicated.} \)
(see e.g. [25], p. 300) with vanishing energy–momentum tensor. As far as the order $O(e)$ is concerned, only the $(0, 3), (1, 3)$ and $(2, 3)$ components of the Ricci tensor give nontrivial results. These components are

\[ R_{03}^{(1)} = -\frac{e^{-\nu}}{2} \left[ \frac{2}{r} h_{13} (2 - \frac{\lambda'}{2} - \frac{\nu'}{2}) + \frac{h_{03}'}{2} \left( \lambda' + \nu' \right) + h_{13}' - h_{03}'' - \frac{2\nu'}{r} h_{03} \right] \]

\[ + \frac{1}{2r^2} (h_{03,22} - h_{03,2} \cot \theta) , \tag{3.8} \]

\[ R_{13}^{(1)} = -\frac{e^{-\nu}}{2} \left( \frac{\dot{h}_{13} - \dot{h}_{03}' + \frac{2h_{03}'}{r}}{r} \right) + \frac{e^{-\lambda}}{r} h_{13} \left( \frac{\lambda'}{2} - \frac{\nu'}{2} - \frac{1}{r} \right) \]

\[ + \frac{1}{2r^2} (h_{13,22} - h_{13,2} \cot \theta) , \tag{3.9} \]

\[ R_{23}^{(1)} = -\frac{e^{-\nu}}{2} \left[ \frac{h_{13,2}' - 2h_{13}' \cot \theta + h_{13} (\lambda' - \nu') \cot \theta + \frac{h_{13,2}'}{2} (\nu' - \lambda')}{2} \right] \]

\[ - e^{-\nu} \left( \frac{h_{03} \cot \theta - \dot{h}_{03,2}}{2} \right) , \tag{3.10} \]

where a dot and a prime denote differentiation with respect to $t$ and $r$, respectively.

We now insert the form of the metric perturbations (3.1)–(3.3) into the Einstein equations (2.21) and use the following property of the function $\Theta^l$ (see Appendix A):

\[ \frac{d\phi \Theta^l}{d\phi^2} - \cot \theta \frac{d\Theta^l}{d\theta} + l(l + 1) \Theta^l = 0 . \tag{3.11} \]

After some manipulations we find \(^7\)

\[ i\omega \left[ h_{1}' + h_{1} \left( \frac{2}{r} - \frac{\lambda'}{2} - \frac{\nu'}{2} \right) \right] - \frac{h_{0}'}{2} (\lambda' + \nu') + h_{0}' - h_{0} \left[ \frac{l(l + 1) e^{\lambda}}{r^2} - \frac{2\nu'}{r} \right] = 0 , \tag{3.12} \]

\[ i\omega e^{-\nu} \left( h_{0}' - \frac{2h_{0}}{r} \right) + h_{1} \left[ \frac{l(l + 1)}{r^2} - \omega^2 e^{-\nu} + \frac{e^{-\lambda}}{r} (\lambda' - \nu' - \frac{2}{r}) \right] = 0 , \tag{3.13} \]

\[ i\omega e^{-\nu} h_{0}' + e^{-\lambda} \left[ h_{1}' + \frac{h_{1}}{2} (\nu' - \lambda') \right] = 0 . \tag{3.14} \]

\(^7\)See Ref. [26] for corrections to the radial equations in Refs. [10, 11]. Also note misprints in the BH Eq. (11) corresponding to our Eq. (3.15). One of the coefficients of $Q$ in our Eq. (3.19) differs by a factor 1/2 from the corresponding one in BH Eq. (14). The sign of the right hand side of our Eq. (3.18) is opposite to that in the corresponding BH equation.
Following BH we can now use Eq. (3.14) to eliminate $h_0$ from Eq. (3.13), obtaining the second order differential equation for $h_1(r)$:

$$h''_1 + h'_1 \left[ \frac{3}{2} (\nu' - \lambda') - \frac{2}{r} \right] + h_1 \left[ \frac{1}{2} (\nu' - \lambda')^2 + \frac{1}{2} (\nu'' - \lambda'') - l(l+1) \frac{e^\lambda}{r^2} + \omega^2 e^{\lambda-\nu} + \frac{2}{r^2} \right] = 0 . \quad (3.15)$$

We introduce the variable $Q$ and the Regge–Wheeler coordinate $r_s$ defined by

$$h_1 \equiv r e^{(\lambda-\nu)/2} Q , \quad (3.16)$$

$$dr_s = e^{(\lambda-\nu)/2} dr . \quad (3.17)$$

In terms of these quantities we have

$$h_0 = -\frac{1}{i\omega} \frac{d(rQ)}{dr_s} \quad (3.18)$$

and

$$\frac{d^2 Q}{dr_s^2} + \left[ \omega^2 + \frac{3}{2r} (\nu' - \lambda') e^{\nu-\lambda} - \frac{l(l+1)}{r^2} \right] Q = 0 . \quad (3.19)$$

This Schrödinger–like equation lends itself to the analogy with the dynamics of waves propagating in an effective potential [1, 10, 11].

At this point BH proceed with the specification of the background metric

$$e^\nu = \begin{cases} 
1/9 & \text{if } r \leq a \\
1 - 2M/r & \text{if } r \geq a 
\end{cases}, \quad (3.20)$$

$$e^\lambda = \begin{cases} 
1 & \text{if } r < a \\
(1 - 2M/r)^{-1} & \text{if } r > a 
\end{cases}, \quad (3.21)$$

where $a = 9M/4$ and $M$ is the geon mass. This vacuum solution for the background metric implies that the effective energy density due to the gravitational waves vanishes for $r \neq a$. Since the effective energy is positive semi–definite, Eqs. (3.20), (3.21) imply that

$$h_{\mu\nu} = 0 \quad \text{for } r \neq a . \quad (3.22)$$

\footnote{An equation similar to Eq. (3.19) can be derived for the even modes with $m = 0$ [30].}
Conversely, if the condition (3.22) is satisfied, the Birkhoff theorem guarantees that the metric is Minkowskian for \( r < a \) and the Schwarzschild metric for \( r > a \).

Therefore, in the BH model, gravitational waves are confined to a spherical shell, the thickness of which is exactly zero. Apparently, BH meant to build a geon model in which the gravitational waves are trapped in a spherical shell which has a nonvanishing thickness which is much smaller than its radius. However, their equations do not allow for this possibility. To be complete, we examine the viability of a geon with gravitational waves confined to a shell whose thickness is exactly zero. It is easy to see that such a model is physically meaningless and that the geon problem becomes mathematically ill-defined in this case. In fact, the solutions of the radial equations (3.12)–(3.15) cannot be ordinary functions but must be sought in some space of *distributions*. In Eq. (3.15), the coefficients proportional to \( \nu' - \lambda' \) and \( \nu'' - \lambda'' \) are not ordinary functions and have a mathematical meaning only if they are regarded as distributions. The first of these two quantities can be expressed as

\[
\nu' - \lambda' = 4Mr^{-2}\left(1 - \frac{2M}{r}\right)^{-1}\theta_H(r-a),
\]

where

\[
\theta_H(x) \equiv \begin{cases} 
0 & \text{if } x < 0 \\
1 & \text{if } x > 0
\end{cases}
\]

is the Heaviside step function. Clearly, the radial derivative of \( \nu' - \lambda' \) can be taken only in a distributional sense. Therefore the solutions of the Einstein equations are distributions and their domain is some space of test functions which must be specified in such a way that the coefficients and the operations involved in the Einstein equations are well defined. There is no indication as to the manner in which this functional space should be determined. It seems almost certain that, if a meaningful and unambiguous mathematical formulation of the problem can be given, the distributional solutions \( h_{\mu\nu} \) cannot be seen as locally integrable functions, but rather must have properties like a Dirac delta with support on \( r = a \). Furthermore, the product of distributions is not defined and the Einstein equations involving the part of the Ricci tensor quadratic in \( h_{\mu\nu} \) and its derivatives is mathematically meaningless in this case. This destroys the possibility of exploring one of the essential features of a gravitational geon. Moreover, if the \( h_{\mu\nu} \) are allowed to be distributions, the whole meaning of the linearization around the background \( \gamma_{\mu\nu} \), the condition \( |h_{\mu\nu}| << 1 \), and the estimates of the different orders of magnitude in the Einstein equations, become meaningless. The physical interpretation of a distributional metric and Riemann tensor is problematic. To appreciate this,
one can consider the much simpler case of a metric which does not satisfy the appropriate junction conditions [28] on a spacelike or timelike hypersurface (this is the case of the metric $\gamma_{\mu\nu}$ given by Eqs. (3.20), (3.21) and the timelike hypersurface $r = a - \delta a$ – see Appendix B). As suggested by Israel [29], and as can be seen from the computation of the Einstein tensor for the spherical metric specified by Eqs. (3.20), (3.21), a singular hypersurface $S$ (in the sense [28] that the first, or the second fundamental form, or both are not continuous at $S$) is associated with nonvanishing $T_{\mu\nu}$, a source of stresses. The definition of a geon, a structure of pure gravitational waves in the absence of matter, excludes the use of a background metric which does not satisfy the proper junction conditions. If, in addition, the “perturbations” $h_{\mu\nu}$ are allowed to be distributions, the consideration of junction conditions loses its meaning, but the argument shows that delta–like sources of stresses are included in the problem. Thus, we exclude the case in which gravitational waves are confined to a shell, the thickness of which is exactly zero, as physically meaningless, mathematically ill-defined, and nonviable.

The only possible alternative for a geon model in which gravitational waves are confined to a spherical shell is the case in which the shell has a nonzero thickness. Apparently, BH meant to consider such a model, although this contradicts some of their equations. To be specific, let us consider a shell of radius $a$ and thickness $\delta a$ described by values of the radial coordinate in the range

$$a - \frac{\delta a}{2} \leq r \leq a + \frac{\delta a}{2},$$

where $0 < \delta a << a$. In order for the geon to be a distribution of pure gravitational fields without matter, we must require that the metric tensor satisfies the appropriate junction conditions [28] at the two timelike hypersurfaces $S_{\pm} = \{(t, r, \theta, \varphi) : r = a \pm \delta a/2\}$. This guarantees the absence of a real (as opposed to “effective”, i.e. generated by gravitational waves) stress–energy tensor $T_{\mu\nu}$ representing a matter distribution. In this model, the modified BH solution would be

$$e^{\nu} = \begin{cases} 
1/9 & \text{if } r \leq a - \frac{\delta a}{2} \\
1 - 2M/r & \text{if } r \geq a + \frac{\delta a}{2}
\end{cases},$$

$$e^\lambda = \begin{cases} 
1 & \text{if } r \leq a - \frac{\delta a}{2} \\
(1 - 2M/r)^{-1} & \text{if } r \geq a + \frac{\delta a}{2}
\end{cases},$$

$$h_{\mu\nu} = 0 \quad \text{if } r < a - \frac{\delta a}{2}, \quad r > a + \frac{\delta a}{2}. \quad (3.28)$$
The form of the background metric $\gamma_{\mu\nu}$ inside the spherical shell is not given by BH and must be determined by solving simultaneously the Einstein equations to the two lowest orders for a pair $(\gamma_{\mu\nu}, h_{\mu\nu})$ [27]. The proper orders of magnitude did not appear in [11] as a consequence of neglecting the high frequency approximation, despite the fact that this was introduced at the beginning of the paper in order to define time averages. These are the reasons why there is only one set of equations in [11] mixing different orders and a complete solution to the geon problem is not provided. It is natural to ask if such a solution based on a spherical shell of nonvanishing thickness is viable. This question will be answered in the next Section.

4 Resolving the geon problem

In this Section we study the geon problem assuming the high frequency approximation, as required, and we take into account the orders of magnitude accordingly. In what follows, we solve the geon problem in the case of a spherically symmetric, static and asymptotically flat background $\gamma_{\mu\nu}$. We solve simultaneously (using numerical methods) the Einstein equations to the two lowest orders for a pair $(\gamma_{\mu\nu}, h_{\mu\nu})$, taking into consideration the boundary conditions (2.26). We do not assume that the metric perturbations vanish outside a certain radius, but rather solve the system of equations throughout space. We consider odd modes only and specialize to $m = 0$. This is analogous to Wheeler's electromagnetic geon. At the end of this Section, the results will be generalized to $\gamma_{\mu\nu}$ being a time-dependent, slowly varying, spherically symmetric background metric.

4.1 Odd modes

To avoid problems which can arise in non-linear equations using a complex exponential to describe the time dependence of the metric perturbations, it is advantageous to rewrite
the individual modes of the RW spherical harmonics in their real form\textsuperscript{9} for $m = 0$:

\[
\begin{pmatrix}
  0 & 0 & 0 & h_0(r) \Theta'(\theta) T_0(t) \\
  0 & 0 & 0 & h_1(r) \Theta'(\theta) T_1(t) \\
  \text{Sym} & \text{Sym} & 0 & 0 \\
  \text{Sym} & \text{Sym} & 0 & 0
\end{pmatrix}
\]

(4.1)

where

\[
\Theta'(\theta) = C_0^0 \sin \theta \frac{d}{d\theta} P^l (\cos \theta)
\]

(4.2)

\[
T_0(t) = \cos(\omega t + \delta)
\]

(4.3)

\[
T_1(t) = \sin(\omega t + \delta), \quad \delta = \text{constant}
\]

(4.4)

The phase constant $\delta$ can be set to zero without loss of generality, because the phase dependence no longer exists upon time averaging.

The Ricci tensor is computed using Eq. (2.16) which, to the dominant order $O(1/\epsilon)$, is simplified to (see Appendix C)

\[
R_{\alpha\beta}^{(i)} \left[ \epsilon^{-1} \right] = \frac{1}{2} \gamma^{\rho\tau} \left( h_{\rho\tau,\alpha\beta} + h_{\alpha\beta,\rho\tau} - h_{\tau\alpha,\beta\rho} - h_{\tau\beta,\alpha\rho} \right).
\]

(4.5)

Substituting Eq. (4.1) into Eq. (4.5) yields the three non-trivial equations

\[
h''_0(r) - \omega h'_1(r) - l^2 r^{-2} e^\lambda h_0(r) = 0,
\]

(4.6)

\[
\omega h''_0(r) + \left( l^2 r^{-2} e^{\nu} - \omega^2 \right) h'_1(r) = 0,
\]

(4.7)

\[
h'(r) + \omega e^{\lambda-\nu} h_0(r) = 0,
\]

(4.8)

from $(\alpha, \beta) = (0,3), (1,3)$ and $(2,3)$ respectively. Eliminating $h_0(r)$ from Eq. (4.7) and (4.8) yield the second order radial wave equation

\[
h''_1(r) + e^\lambda \left( \omega^2 e^{\nu} - \frac{l^2}{r^2} \right) h_1(r) = 0
\]

(4.9)

\textsuperscript{9}Ref. [15] used $T_0 = T_1 = \cos(\omega t)$, which is not the most general case. The functions $T_0$ and $T_1$ are constrained by the $(0,3)$ component of the Einstein equations.
for the radial function $h_1(r)$. It should be noted that in the high frequency limit, the angular momentum quantum number $l \gg 1$, hence Eq. (3.11) takes the form

$$\frac{d^2\Theta^l}{d\theta^2} + l^2 \Theta^l = 0$$

(4.10)

and is used in obtaining Eqs. (4.6)–(4.9) (note that $\cot \theta d\Theta^l/d\theta$ in Eq. (3.11) is of higher order than the retained terms in Eq. (4.10) in the high frequency limit). The next step is to determine the order $O(1)$ equations. Instead of evaluating Eq. (2.23), we can equivalently evaluate

$$R_{\mu\nu}^{(0)}(\gamma) - \frac{1}{2} \gamma_{\mu\nu} R^{(0)}(\gamma) = -\left\langle R_{\mu\nu}^{(2)}[\epsilon^0] - \frac{1}{2} \gamma_{\mu\nu} R^{(2)}[\epsilon^0] \right\rangle .$$

(4.11)

By defining the Brill–Hartle space-time averaged stress–energy tensor as

$$T_{\mu\nu}^{\text{BH}} = \left\langle T_{\mu\nu} \right\rangle = -\frac{1}{8\pi} \left\langle R_{\mu\nu}^{(2)}[\epsilon^0] - \frac{1}{2} \gamma_{\mu\nu} R^{(2)}[\epsilon^0] \right\rangle = -\frac{1}{8\pi} \left\langle G_{\mu\nu}^{(2)}[\epsilon^0] \right\rangle ,$$

(4.12)

Eq. (4.11) takes the familiar form

$$G_{\mu\nu}^{(0)}(\gamma) = 8\pi T_{\mu\nu}^{\text{BH}} ,$$

(4.13)

of an effective stress-energy tensor generating the background metric $\gamma_{\mu\nu}$.

The procedure for finding the average over the angular dependence of $T_{\mu\nu}$ has been given by Wheeler (see ref. [1], p. 520). The results are directly applicable to the gravitational geon since the discussion covers general $T_{\mu\nu}$. Hence, we have for the time-angle average (denoted $\langle \rangle_{\tau\theta}$) of $T_{\mu\nu}$ (denoted $\langle \rangle_{\tau\theta}$) of $T_{\mu}^{\nu}$ summed over all $N$ active modes

$$\left\langle 8\pi T_{0}^{0} \right\rangle_{\tau\theta} = -\frac{N}{2} \int \left\langle G_{[i]0}^{(2)0} \right\rangle_{\tau} \sin \theta \, d\theta ,$$

(4.14)

$$\left\langle 8\pi T_{1}^{1} \right\rangle_{\tau\theta} = -\frac{N}{2} \int \left\langle G_{[i]1}^{(2)1} \right\rangle_{\tau} \sin \theta \, d\theta ,$$

(4.15)

$$\left\langle 8\pi T_{2}^{2} \right\rangle_{\tau\theta} = \left\langle 8\pi T_{3}^{3} \right\rangle_{\tau\theta} = -\frac{N}{2} \int \left\langle G_{[i]2}^{(2)2} + G_{[i]3}^{(2)3} \right\rangle_{\tau} \sin \theta \, d\theta ,$$

(4.16)

$$\left\langle 8\pi T_{\mu}^{\nu} \right\rangle_{\tau\theta} = 0 \text{ for } \mu \neq \nu .$$

(4.17)
Here $\langle \rangle_\tau$ denotes a time average, and $G^{(2)}_{\mu}$ is mode number I of the disturbance under discussion. Using the mixed form of Eq. (2.17) in conjunction with Eqs. (4.1) and (4.8), and performing the time and angle averaging (see Appendix D), we obtain

$$
\langle 8\pi T^0_0 \rangle_{\tau A} = -\frac{N (C^\mu)^2}{8\pi^2 e^{\lambda}} \left[ -\frac{3}{2} \omega^2 h_1^2 e^{-\nu} - e^{-\lambda} \left( 2h_1^\mu h^\nu_1 - h^\mu_1 \right) 
- \omega^{-2} e^{-\nu-2\lambda} \left( \frac{1}{2} h^\mu_1 - h^\mu_1 h^\nu_1 \right) + \frac{1}{2} \frac{1}{R^2} \omega^{-2} \left( e^{-\nu-\lambda} h^\mu_1 + h^2_1 \right) \right],
$$

$$
(4.18)
$$

$$
\langle 8\pi T^1_1 \rangle_{\tau A} = \frac{N (C^\mu)^2}{8\pi^2 e^{\lambda}} \left[ \omega^{-2} e^{-\nu-2\lambda} \left( h_1^\mu h^\nu_1 - \frac{1}{2} h^\mu_1 h^\nu_1 \right) + e^{-\lambda} h^\mu_1 
+ \frac{1}{2} e^{-\nu} \omega^2 h_1^2 - \frac{1}{2} \frac{1}{R^2} \omega^{-2} \left( e^{-\nu-\lambda} h_1^2 + h_1^2 \right) \right].
$$

$$
(4.19)
$$

We see from Eq. (4.16) that the (2,2) field equation must be identical to the (3,3) equation. Neither are necessary to solve the geon problem since the complete system of equations must be self consistent. The latter two equations may be derived from the (1,1), (0,0) and wave equations. It is of interest to compare Eqs. (4.18)-(4.19) with their electromagnetic counterparts. The following equations are given in Ref. [1] and are not restricted to the high frequency approximation:

$$
\langle 8\pi T^1_1 \rangle_{\tau A} = \frac{N l(l+1)}{2(2l+1)} \left[ e^{-\lambda} \left( \frac{dR}{r dr} \right)^2 + e^{-\nu} \left( \frac{\Omega R}{r} \right)^2 - l(l+1) \left( \frac{R}{r^2} \right)^2 \right],
$$

$$
(4.20)
$$

$$
\langle 8\pi T^0_0 \rangle_{\tau A} = \frac{N l(l+1)}{2(2l+1)} \left[ -e^{-\lambda} \left( \frac{dR}{r dr} \right)^2 - e^{-\nu} \left( \frac{\Omega R}{r} \right)^2 - l(l+1) \left( \frac{R}{r^2} \right)^2 \right].
$$

$$
(4.21)
$$

Here $R = R(r)$ is the electromagnetic counterpart of $h_1(r)$. It is evident that the similar terms (same differential order) in $T^0_0$ for the gravitational case have a sign difference. For the $T^0_0$ component, one of the three similar terms has a sign difference. These sign differences play an important role in the subsequent solving of the gravitational geon problem. It will be shown that the sign differences lead to a negative mass for the gravitational geon as the only non-trivial solution to the field equations. It is understandable that these sign differences should arise: in the electromagnetic case, the source is designed at will (subject to the Maxwell equations) and appears on the right hand side of the Einstein equations. By contrast, the gravitational source is artificially
constructed from terms on the left hand side of the Einstein equations which are shifted to the right hand side.

The left hand side of Eq. (4.13) is

\[ G^{(0)}_0 = e^{-\lambda} \left( r^{-2} - r^{-1}\lambda' \right) - r^{-2}, \]

(4.22)

\[ G^{(0)}_1 = e^{-\lambda} \left( r^{-2} + r^{-1}\nu' \right) - r^{-2}. \]

(4.23)

The equations for the proposed gravitational geon have the same scale invariance as those for the electromagnetic counterpart. Therefore we can introduce the same dimensionless measure of radial coordinate, \( \rho = \omega r \). By analogy with the electromagnetic case, we can define a new measure of potential

\[ f(\rho) = \sqrt{k^4} \omega h_1(r), \quad \text{where} \quad k^4 \equiv \frac{1}{8} lN \left( C^{(0)} \right)^2, \]

(4.24)

and two metric functions \( L(\rho) \) and \( Q(\rho) \) such that

\[ e^{-\lambda} \equiv 1 - 2\rho^{-1} L(\rho), \]

(4.25)

\[ e^{\lambda + \nu} \equiv Q^2(\rho), \]

(4.26)

\[ e^\nu = \left[ 1 - 2\rho^{-1} L(\rho) \right] Q^2(\rho). \]

(4.27)

Substituting the above into Eqs. (4.9), (4.18)–(4.23) yields the wave equation

\[ \frac{d^2 f}{d\rho^2} + \left[ 1 - \left( \frac{lQ}{\rho} \right)^2 \left( 1 - \frac{2L}{\rho} \right) \right] f = 0, \]

(4.28)

where

\[ d\rho^* = Q^{-1} \left( 1 - \frac{2L}{\rho} \right)^{-1} d\rho, \]

(4.29)

and the two background equations

\[ \frac{dL}{d\rho^*} = - \frac{(1 - 2L/\rho)}{2Q} \left[ \frac{3}{2} f^2 + 2f \frac{d^2 f}{d\rho^2} + \left( \frac{df}{d\rho^*} \right)^2 \right. \]

\[ + \left. \frac{1}{2} \left( \frac{d^2 f}{d\rho^2} \right)^2 + \frac{df}{d\rho^*} \frac{d^3 f}{d\rho^3} - \frac{1}{2} \rho^2 f Q^2 (1 - 2L/\rho) \left( \left( \frac{df}{d\rho^*} \right)^2 + f^2 \right) \right], \]

(4.30)
\[
\frac{dQ}{d\rho} = -\frac{(1 - 2L/\rho)}{\rho - 2L} \left[ f^2 + f \frac{d^2 f}{d\rho^2} + \left( \frac{df}{d\rho} \right)^2 \right] \\
+ \frac{d\rho}{\rho} \frac{d^3 f}{d\rho^3} - \frac{1}{2} \rho^{-2} L^2 Q^2 \left( 1 - 2L/\rho \right) \left( \left( \frac{df}{d\rho} \right)^2 + f^2 \right) \right). \quad (4.31)
\]

As in the electromagnetic case, the above equations permit a further change of scale without change of form:

\[
\rho = b\rho_1, \quad Q = bQ_1, \quad \rho^* = \rho_1^*, \quad L = bL_1, \quad f = b^{1/2} f_1. \quad (4.32)
\]

This allows \( Q_1(0) \equiv 1 \) and then the scaling parameter can be found by demanding \( Q(\infty) = 1 \). Note that in Eqs. (4.30) and (4.31) (and in Wheeler’s electromagnetic study), an average over a length larger than the characteristic wavelength of the radial function \( f(\rho) \) has not been performed. This would enormously complicate the system of equations (4.28)–(4.31) and was not believed to be necessary in Ref. [1]. Our approach parallels that of Ref. [1].

Since the wave equation for the proposed gravitational geon is identical to the one for the electromagnetic counterpart, the same arguments hold for applying another scaling law valid asymptotically for large \( l \) (the high frequency of the gravitational waves guarantees large \( l \)). By making the transformation

\[
x = (\rho^* - l) l^{-1/3},
\]

the entire active region of the proposed geon will be described by a range of \( x \) of order unity. Wheeler [1] has provided the expansion of the relevant quantities in inverse powers of \( l^{1/3} \). They are

\[
\begin{align*}
\frac{d\rho}{dx} &\equiv l^{-1/3}dx, \\
\rho_1 &= l + l^{1/3} r_0(x) + \cdots, \\
L_1 &= l \lambda_0(x) + l^{2/3} \lambda_1(x) + l^{1/3} \lambda_2(x) + \cdots, \\
Q_1 &= 1/k(x) + l^{-1/3} q_1(x) + l^{-2/3} q_2(x) + \cdots, \\
f_1 &= l^{1/3} \phi(x) + \phi_1(x) + l^{-1/3} \phi_2(x) + \cdots.
\end{align*}
\]

After substituting Eq. (4.34) into (4.28), expanding in inverse powers of \( l^{1/3} \) and setting the lowest three orders to zero, we find the two algebraic equations

\[
\lambda_0 = \frac{1}{2} \left( 1 - k^2 \right), \quad (4.35)
\]

19
\[ \lambda_1 = q_1 k^3, \quad (4.36) \]

and the differential equation
\[ \frac{d^2 \phi}{dx^2} + j(x) k(x) \phi(x) = 0. \quad (4.37) \]

Here, we have defined
\[ j(x) = \frac{1}{k^3} \left( -r_0 - 2q_2 k^3 + 2\lambda_2 + 3q_1^2 k^4 + 3k^2 r_0 \right) \quad (4.38) \]

after using Eqs. (4.35) and (4.36). Repeating this procedure for Eq. (4.30), we obtain
\[ \frac{dk}{dx} = \frac{1}{2} k^2 \phi^2, \quad (4.39) \]
\[ \frac{dq_1}{dx} = -\phi \phi_1, \quad (4.40) \]
\[ \frac{d\lambda_2}{dx} + \frac{1}{4} k^3 r_0 \phi + \frac{9}{4} q_1^2 k^5 \phi^2 - 3q_1 k^4 \phi \phi_1 + \frac{1}{2} k^3 \phi_1^2 + \frac{1}{4} k^3 \left( \frac{d\phi}{dx} \right)^2 \]
\[ + \phi \phi_2 k^3 + k^3 \phi \frac{d^2 \phi}{dx^2} - q_2 k^4 \phi^2 - \frac{1}{2} \lambda_2 k \phi^2 + \frac{1}{4} k r_0 \phi^2 = 0. \quad (4.41) \]

The expansion of Eq. (4.31) yields Eqs. (4.39), (4.40) and
\[ \frac{dq_2}{dx} + r_0 \phi^2 - q_2 k \phi^2 + \frac{1}{2} \phi_1^2 + \lambda_2 k^{-2} \phi^2 + \frac{1}{2} \left( \frac{d\phi}{dx} \right)^2 \]
\[ + \phi \phi_2 + \phi \frac{d^2 \phi}{dx^2} + \frac{3}{2} q_1 k^2 \phi^2 - \frac{1}{2} r_0 \phi^2 k^{-2} = 0. \quad (4.42) \]

By differentiating Eq. (4.38), utilizing Eqs. (4.35), (4.36), (4.39), (4.40)–(4.42) and substituting
\[ \frac{dr_0}{dx} = k \quad (4.43) \]
(derived from Eqs. (4.29) and (4.34)), we obtain the differential equation
\[ \frac{dj(x)}{dx} = 3 - \frac{1}{k^2} \left[ 1 - \frac{1}{2} k^2 \left( \frac{d\phi}{dx} \right)^2 \right]. \quad (4.44) \]
Solving Eqs. (4.37), (4.39) and (4.44) simultaneously for the three functions $\phi(x)$, $j(x)$ and $k(x)$ is sufficient for determining the remaining leading terms in Eq. (4.34). It should be noted that since Eqs. (4.37), (4.39) and (4.44) do not explicitly depend on $x$, the system of equations is autonomous. Hence, if $\phi(x)$, $j(x)$ and $k(x)$ are solutions, then so are $\phi(x+a)$, $j(x+a)$ and $k(x+a)$ where $a$ is a constant. Thus the gravitational geon problem is reduced to finding a solution to the system

$$\frac{d^2\phi}{dx^2} + j(x)k(x)\phi(x) = 0, \quad (4.45)$$

$$\frac{dk}{dx} = \frac{1}{2}k^2\phi^2, \quad (4.46)$$

$$\frac{dj(x)}{dx} = 3 - \frac{1}{k^2}\left[1 - \frac{1}{2}k^2\left(\frac{d\phi}{dx}\right)^2\right], \quad (4.47)$$

with the following properties (which are identical to the conditions for the electromagnetic geon problem):

1. **For large negative $x$:** The field factor $\phi(x) \to 0$ and $k(x) \to 1$. Under these conditions $dj(x)/dx = 2$ or $j(x) = 2x$. Choosing the integration constant for $j(x) = 2x$ to be zero fixes $a$ and consequently defines the origin of $x$. This removes any ambiguity in the start of the integration process. Thus for large negative $x$, $\phi(x)$ satisfies the equation

$$\frac{d^2\phi}{dx^2} = 2x\phi(x). \quad (4.48)$$

The approximate solution as given by Wheeler [1] is

$$\phi(x) \equiv \frac{A}{3}(-2x)^{-1/4}\exp[(-2x)^{3/2}]. \quad (4.49)$$

2. **For large positive $x$:** It is required that $\phi(x) \to 0$, $0 < k(x) < 1$ and $j(x)$ approach large negative values.

The only free parameter is the amplitude $A$ of the wave and this must be chosen so that the solution fits the boundary conditions. The non-linearity of the problem makes it necessary to integrate the system of equations numerically. The integration is started at $x = -4$. The initial conditions are as follows:

$$\phi(-4) = \phi_0 = \text{arbitrary}, \quad (4.50)$$
\[
\frac{d\phi}{dx}\bigg|_{x=-4} = \left(\frac{1}{16} + \sqrt{8}\right)\phi_0, \quad (4.51)
\]
\[
k(-4) = 1, \quad (4.52)
\]
\[
j(-4) = -8. \quad (4.53)
\]

Figure 1 shows the result of the numerical integration using a variable step fourth-fifth order Runge-Kutta method.

In order to understand the significance of the curves plotted in Fig. 1, it would be beneficial to briefly review some of the properties of the proposed electromagnetic geon solution. The differential equations for the electromagnetic case are

\[
\frac{d^2\phi}{dx^2} + j(x)k(x)\phi(x) = 0, \quad (4.54)
\]
\[
\frac{dk}{dx} = -\phi^2, \quad (4.55)
\]
\[
\frac{dj(x)}{dx} = 3 - \frac{1}{k^2} \left[1 + \left(\frac{d\phi}{dx}\right)^2\right]. \quad (4.56)
\]

The initial conditions for these equations are given by Eqs. (4.50)-(4.53) at \( x = -4 \).

The “active region” of the geon is defined to be the range of \( \rho \) where the square bracketed combination of terms in Eq. (4.28) is positive. In this region, the function \( f(\rho) \) has oscillatory behaviour. Where the bracketed terms are negative, the behaviour of \( f(\rho) \) is exponential growth or decay. The active region can be identified in the \( x \) coordinate system as the region where the oscillating factor \( j(x)k(x) \) is positive. The mass of the geon inside radius \( \rho \) is related to the function \( k(x) \) in the following way:

\[
M(\rho(x)) = \frac{1}{b} \lambda_0(x) = \frac{1}{2b} \left(1 - k^2\right), \quad (4.57)
\]

with \( b = 1/Q_1(\infty) = k(\infty) \). This implies that

\[
0 \leq k(x) \leq 1 \quad \text{or as } x \to \infty \quad (4.58)
\]
in order to have a positive total mass.

An eigenvalue solution for Eqs. (4.54)-(4.56) is sought for which \( \phi(x) \to 0 \) as \( x \to \infty \). If the amplitude factor \( A \) (which translates into an initial choice of the field factor \( \phi_0 \)) is slightly higher than the desired eigenvalue, \( \phi(x) \) reaches a minimum and then rises
exponentially and becomes singular at some finite \( x \). For an amplitude slightly less than the eigenvalue, \( \phi(x) \) goes to \(-\infty\) at a finite \( x \).

Figures 2 and 3 show that the first eigenvalue (characterized by \( \phi(x) \), having one maxima and no local minima) appears to lie between those amplitude factors \( A \), that correspond to initial values of \( \phi_0 \) at some point in the range \( 9.790419489 \times 10^{-5} < \phi_0 < 9.790419490 \times 10^{-5} \). The mass factor \( k(x) \) give a positive mass throughout the integrable region (before the singularity) and appears to have a \( k(\infty) \) value of approximately 1/3. The function \( j(x) \) is positive only for a limited range in the neighbourhood of \( x = 1 \), thus identifying the active region. Qualitatively, these results are similar to Wheeler’s computations. The only main difference between Wheeler’s calculation and the present one is that his first eigenvalue lies at some point in the range \( 10^{\text{30}00} \times 10^{-4} < \phi_0 < 1.03125 \times 10^{-4} \) and the active region starts at \( x = 4.05 \) and ends at \( x = 6.02 \).

For the proposed gravitational geon, the behaviour of the functions is quite different from that of the electromagnetic case. This is evident in the differential equations themselves. Comparing Eqs. (4.55) and (4.46), there is a sign difference on the right hand side of the equations. This is the manifestation of the sign difference identified earlier in the comparison of the electromagnetic and gravitational stress–energy tensors. Proceeding with the analysis of the equations, Fig. 1 shows the results of the integration of \( \phi(x) \), \( k(x) \) and \( j(x) \) for the initial value \( \phi_0 = 4.45 \times 10^{-4} \). The factor \( j(x)k(x) \) becomes positive at approximately \( x = 0 \) and singular at approximately \( x = 1 \). Since \( j(x)k(x) \) never becomes negative again, it implies that there is no end to the active region and as a consequence, \( \phi(x) \) remains oscillatory for large \( x \). Of an even more disturbing nature, the function \( k(x) \) appears greater than 1 for all \( x \) and approaches \(+\infty\). The implication of this is that the mass of the proposed gravitational geon is negative. As \( \phi_0 \) is decreased (increased), the singular behaviour of \( k(x) \) and \( j(x) \) moves to larger (smaller) values of \( x \), but \( k(x) \) remains greater than 1 and \( j(x) > 0 \) once it becomes positive. Apparently, the only physical solution would be for \( \phi_0 = 0 \), which yields \( k(x) = 1 \) and hence a zero mass gravitational geon. Thus we conclude that it is not possible to construct a gravitational geon and the only physical solution is the trivial solution.

### 4.2 The time–dependent and stationary cases

The previous results can be generalized to the case of a time–dependent, spherically symmetric background metric \( \gamma_{\mu \nu}(t, r) \), under the assumption that its time variation occurs on a scale much larger than the period of the gravitational waves. In this case the high frequency approximation and Eqs. (2.11)–(2.14) remain valid. Equation (2.2)
still holds, but Eq. (2.3) is replaced by
\begin{align}
\lambda &= \lambda(t, r), \\
\nu &= \nu(t, r).
\end{align}

As a consequence of the fact that the estimate of the orders of magnitude in the Einstein equations does not change, we find in this case the same equations that were presented above for the odd modes, and the same conclusions apply. If instead, the background metric $\gamma_{\mu\nu}(t, r)$ is allowed to vary on a time scale comparable to the period of the gravitational waves, the high frequency approximation does not hold and a gravitational geon cannot be constructed, as explained in Sec. 2. This remains valid for any time-dependent background metric $\gamma_{\mu\nu}(t, \vec{x})$ when symmetries are absent, due to the fact that our considerations based on Eq. (2.23) do not rely on the assumption of spherical symmetry. Apart from this argument, the realization of a geon with a rapidly varying background metric $\gamma_{\mu\nu}$ is problematic for another reason: If a spherically symmetric background is allowed to vary harmonically with frequency $\Omega$ comparable to the frequency of the gravitational waves, one expects a parametric resonance [31] for the modes with $\omega = n\Omega/2$, with $n = 1, 2, \cdots$. The strength of the resonance is a maximum for $n = 1$ and decreases rapidly as $n$ increases. In the limit of a static background, the resonance phenomenon disappears. Accordingly, on the basis of studies of perturbations of black holes and relativistic stars [20], it is expected that in the case of a stationary axisymmetric background metric describing a rapidly rotating geon, the resonance phenomenon between the perturbations and the background metric occurs. In the general case of a time-dependent and rapidly varying background metric $\gamma_{\mu\nu}(t, \vec{x})$ without symmetries, it is not known how to decompose metric perturbations on a complete set playing the role of the tensor spherical harmonics in the spherical case, or even how to define frequencies in the strong curvature region. However, if such concepts can be given a meaning, it seems reasonable to expect some kind of resonance phenomena between the background metric and its gravitational wave perturbations. All these resonance phenomena certainly do not contribute to the realization of a stable configuration, but rather are associated with instabilities that tend to disrupt the system.

5 Other approaches to the geon problem

In the previous sections, we have analyzed the BH construct and the models of gravitational geons conceived by Wheeler. However, one can study different models of a gravitational geon and different, independent, approaches to the geon problem, which are given in the present Section.
A first argument, which provides additional intuitive physical insight, is the following: We recall our analogy of Sec. 2 between gravitational waves composing a geon and stars composing a galaxy. The high frequency approximation required in the geon case has a parallel in the case of a galaxy; it corresponds to the requirement that the individual stars have a very high velocity. It is clear that such stars would escape from the galaxy and would not be trapped by its potential well. A galaxy cannot be built exclusively from such stars in rapid motion. In other words, the system would not satisfy the virial theorem and would not be bounded. The difference with the gravitational geon case is that while one is not obliged to require that stars have a very high velocity when constructing a galactic model, the high frequency approximation is necessary for a geon and this, in turn, prevents its realization.

An independent argument to understand the impossibility of a gravitational geon is the following: it is well known that, in the limit of high frequencies, gravitational waves obey the laws of geometric optics [21, 24]. Spatially closed lightlike geodesics exist only inside black holes, which necessitate the existence of singularities. Thus, they are necessarily inconsistent with the definition of a geon. The null circular geodesic at \( r = 3M \) in the Schwarzschild geometry is unstable. It is therefore hard to reconcile high frequency gravitational waves with stable trapped graviton trajectories in the absence of matter.

The most intuitive model of a gravitational geon is that of a ball of high frequency gravitational radiation, which behaves like a perfect fluid with a radiation equation of state. It appears that Wheeler was aware of this possibility, but discarded it as non-viable and therefore proceeded to study the more complicated models of Ref. [1], in which the waves do not propagate radially and the radiation is not isotropic. "... one naturally recalled that some stars derive their energy almost exclusively from particles; others, from a mixture of particles and radiation. The extreme limit of a system deriving its mass-energy from radiation alone therefore suggested itself. However, with no matter to provide opacity and to dam up the radiation against escape, stability could only be maintained by excluding all photon orbits in which the motion is purely radial or largely radial ..." [33]. However plausible this argument may appear, it relies on the theory of the stability of Newtonian stars, and cannot be used for a relativistic fluid ball, since in general relativity the fluid pressure contributes to the energy density which may bind the fluid and this contribution cannot be neglected in a relativistic star dominated by radiation pressure. Therefore, it is important to re-examine the possibility of a fluid ball made only of gravitational waves. There have been some papers (see [2, 3] and references therein) analyzing the properties of self-gravitating electromagnetic radiation confined to a spherical box. The radiation is taken to be a perfect fluid with
equation of state \( p = \rho/3 \). This model is as applicable to high frequency gravitational waves as it is to electromagnetic waves, hence the results of these papers will hold true for gravitational radiation. In order to build a geon (both electromagnetic and gravitational), the constraint of the spherical box (with reflecting walls) would have to be removed. This requirement leads to the impossibility of constructing any type of geon using a relativistic perfect fluid model. Weinberg [32] has shown that a highly relativistic fluid with \( p = \rho/3 \) can never achieve hydrostatic equilibrium in a finite ball through gravity alone. The relativistic equation for hydrostatic equilibrium is

\[
- \frac{\partial p}{\partial x^\lambda} = (p + \rho) \frac{\partial}{\partial x^\lambda} \ln \left[ \frac{(-g_{00})^{1/2}}{h_0} \right]. \tag{5.1}
\]

For \( p = \rho/3, \rho \propto (-g_{00})^{-(p+\rho)/2p} \). Since \( \rho \) must vanish outside the fluid, \( g_{00} \) would have to become singular at its surface. If the surface of the ball is allowed to extend to spatial infinity, then from Sokolov’s work [3], it is not difficult to establish that the mass of the radiation ball diverges (see also Ref. [24], p. 615, ex. 23.10).

Another work which casts doubt on the existence of electromagnetic geons is that of Gibbons and Stewart [34]. They conclude that the Einstein equations do not permit asymptotically flat solutions which are both periodic and empty near infinity. This precludes the existence of gravitational geons for at least the periodic case. They also suggest that the result may be extended to include the case when there is matter near infinity, e.g., electromagnetic or scalar radiation.

6 Discussion and conclusion

The results of the previous sections were derived by making use of some particular gauge conditions that RW imposed in order to set the metric perturbations in the form of Eqs. (2.6) and (2.7). However, it is clear from their very nature that our results are covariant and gauge-independent, since the solution \((\gamma_{\mu\nu}, h_{\mu\nu}) = (\eta_{\mu\nu}, 0)\) that we found has an invariant meaning (for example, the vanishing of the curvature tensor is a covariant concept).

Since a spherically symmetric gravitational geon cannot exist due to the fact that the high frequency approximation does not allow a solution with the required characteristics, one might ask if it is possible to realize a gravitational geon in a configuration with less symmetry. We do not expect that such a geon can be constructed when the most primitive case is excluded. The main reason for this belief is that the key factor which leads to the non-existence of the spherical geon is not the spatial symmetry but rather the high frequency.
From a mathematical point of view, the main difference between our approach to the geon problem, as compared to that of BH, consists in our explicit use of the high frequency approximation in conjunction with solving explicitly for the wave and background metric functions in a self-consistent manner. We have already seen in Sec. 2 that this is necessary for the geon problem to be meaningful. In Sec. 4 it was shown that the same approximation prevents the realization of a spherically symmetric geon.

In his papers on geons, Wheeler [1, 4, 7, 8] describes electromagnetic and neutrino geons as systems which are stable on a long time scale, but not absolutely stable, in the sense that they “leak” radiation to the exterior. The rate of the leaking is negligible, so that a geon is stable for a long period of time. However a secular instability is introduced, which seems unavoidable [7]. The BH model of a spherical shell with \( h_{\mu\nu} \) exactly equal to zero outside a certain radius excludes such a possibility, and it could be conjectured that this might be the reason why their model is not viable, leaving a possibility open for the realization of physically more realistic “leaking” geons\(^{10}\). However, this possibility is excluded by our calculations. In fact our boundary conditions (2.26) allow for this possibility, which in turn is excluded by our results as well.

It should be noted that while there is a marked contrast between the characteristics of proposed gravitational and electromagnetic geons as evidenced in Figs. 1, 2 and 3, it is still unclear that even an electromagnetic geon is a viable entity. This is because the electromagnetic geon plots do not display true soliton-like confinement. Rather they show a region which, by very high refinement of the eigenvalue, is very near vacuum but which is followed by an infinite amount of energy beyond this region. It was contended [1] that by continued refinement of the eigenvalue, this infinite energy region would itself be pushed out to infinity. Firstly, it is not clear that this really is the case and it is possible that infinite refinement of the eigenvalue could lead to a convergence of the infinite energy regime at some finite distance from the vacuum region. Such would clearly be unacceptable as a model of the desired confined energy concentration. Secondly, even if it is the case as was conjectured, that continued refinement of the eigenvalue would push the infinite energy regime out to infinity, this would not appear to be the idealized soliton-like structure that is being sought.

Traditionally, the geon was conceived as a structure of small-amplitude high-frequency gravitational waves compactified to the point where one could describe the resulting met-

\(^{10}\)There is inconsistency in [11] at this point: in that paper it is required that \( h_{\mu\nu} \) (and therefore \( Q \)) vanishes outside the spherical shell. However, the Schrödinger-like equation that is derived there for \( Q \) (our Eq. (3.19)) implies a “leaking” geon, as is stated in [11]. In fact, the function \( Q \) has a nonvanishing tail for large values of the radius, due to the fact that the effective potential barrier is finite. This effect is analogous to the well-known tunnel effect in quantum mechanics.
ric as the averaged “background” metric induced by the totality of the waves plus a small perturbation due to the local wave presence. This is what was analyzed in the present work. It is natural to consider also waves of “large” amplitude in which case linearization is no longer possible nor is it meaningful to envisage a splitting of the metric as before. In fact, to assign a measure to amplitude presupposes a standard for comparison and in the present work, the background metric served this role. To speak now of large amplitude is to consider waves for which there is no longer a discernible “background” and hence no standard for comparison of amplitude measure. This leads to the realm of exact solutions. One might ask whether an exact wave-like solution of the Einstein equations, singularity-free with localized curvature and asymptotically flat, could exist. Existing exact wave-like solutions such as the plane waves of Bondi, Pirani and Robinson or the cylindrical waves of Einstein and Rosen are not localized and in the second case, are also not singularity-free. While it would appear doubtful that solutions with the geon-like properties can exist, to our knowledge they are not ruled out.

Implicit in the gravitational geon concept is the assumption that the gravitational field has some particular essential features shared by other fields. Other fields, even in their pure states, carry energy. Energy has a mass equivalent and all masses gravitate. Thus, given a sufficient concentration of field energy, one could imagine a gravitated concentration into a spherical region with the effective mass displayed unambiguously by the coefficient of the $1/r$ part of the asymptotic static vacuum metric. The gravitational geon concept is built upon the assumption that the gravitational field itself, even in its pure state, will gravitate and thus have the potential to behave as other concentrations of matter or fields. Through the years, various authors such as Isaacson have dwelt upon the similarities between the gravitational and other fields. For example, Isaacson has attempted to establish that there is a basis for considering a certain construct of the metric as an energy-momentum tensor of the gravitational field which is as substantial as a true energy-momentum tensor. However, this requires averaging and under the appropriate limits, his construct merges with the energy-momentum pseudotensor, the shortcomings of which epitomize the gravitational energy problem. If the gravitational field in its pure form really did have the properties which those authors have ascribed to it, then it would seem reasonable to expect that a gravitational geon could, at the very least in principle, be constructed. However, given the present results, it is worth considering alternative ideas.

Recently, one of the authors introduced a new hypothesis that gravitational energy is localized in regions of non-vanishing energy-momentum tensor. The motivation derived from the fact that the traditional means by which physicists have identified gravitational energy was through the covariant energy-momentum conservation laws.
While those laws were extrapolated to produce energy–momentum pseudotensors, implying densities and fluxes even in vacuum, the fact is that the laws themselves are devoid of content in vacuum, producing the empty identity $0 = 0$. Given that there is a plethora of possible pseudotensors and, as their name implies, they are not really tensors, it was suggested [35] that the root of the ambiguity lies in the extrapolation of the conservation laws to regions in which they are without actual content. The hypothesis goes on to propose that the true expression of the gravitational contribution to energy is confined to regions of non–vanishing $T_{\mu\nu}$. In a sense this is the opposite of the Isaacson approach in that rather than being satisfied with a construct which reduces to the pseudotensor, the new hypothesis suggests that proper localization is realized when the pseudotensor is removed.

Clearly, the realization of a gravitational geon would negate the new hypothesis as it would provide an example of a space totally free of true energy–momentum tensor $T_{\mu\nu}$ yet exhibit an unambiguous energy content via its asymptotic metric. While one might propose exact plane gravitational wave solutions as counter–examples to the hypothesis, it is to be noted that these are unbounded fields with questionable relevance to physical situations and more directly, these wave solutions can be expressed in Kerr–Schild form for which the pseudotensor vanishes in its entirety [37]. The gravitational geon is a direct challenge to the hypothesis and if the geon cannot exist, the hypothesis has passed another test.

**Acknowledgments**

We are grateful to several colleagues for helpful criticisms. This research was supported, in part, by a grant from the Natural Sciences and Engineering Research Council of Canada.

**Appendix A: Derivation of Eq. (3.11)**

We start from the Legendre equation

$$\frac{d}{dx} \left[ (1 - x^2) \frac{dP_l(x)}{dx} \right] + l(l + 1) P_l(x) = 0$$  \hspace{1cm} (A.1)

and note that

$$\Theta_l(\theta) = C^{l0} \sin \theta \frac{dP_l(\cos \theta)}{d\theta} = C^{l0} \left( x^2 - 1 \right) \frac{dP_l(x)}{dx} ,$$  \hspace{1cm} (A.2)
where \( x = \cos \theta \). Using
\[
\frac{d}{d\theta} = -\sin \theta \frac{d}{dx}, \quad \frac{d^2}{d\theta^2} = \sin^2 \theta \frac{d^2}{dx^2} - \cos \theta \frac{d}{dx},
\]
and the Legendre equation (A.1), we find the relations
\[
\frac{d\Theta^l}{d\theta} = -l(l+1)C^{l0} \sin \theta P^l(x), \quad (A.5)
\]
\[
\frac{d^2\Theta^l}{d\theta^2} = -l(l+1)C^{l0} \left[ xP^l(x) + (x^2 - 1) \frac{dP^l(x)}{dx} \right]. \quad (A.6)
\]
Using Eqs. (A.5) and (A.2) in Eq. (A.6), Eq. (3.11) follows.

**Appendix B: Junction conditions for the BH background metric**

We consider the Darmois junction conditions [28] for the BH background metric on the timelike hypersurface \( S \equiv \{(t, r, \theta, \varphi) : \ r = a \} \) separating the regions of the space-time manifold \( U \equiv \{(t, r, \theta, \varphi) : \ r < a \} \), \( \bar{U} \equiv \{(t, r, \theta, \varphi) : \ r > a \} \). \( \{x^\alpha\} = \{\bar{x}^\alpha\} = \{t, r, \theta, \varphi\} \) and \( \{u^i\}_{i=0,2,3} = \{t, \theta, \varphi\} \) are coordinate systems in \( U, \bar{U} \) and \( S \), respectively (note that, in this Appendix, Latin indices assume the values 0, 2, 3 due to the timelike character of \( S \)). The unit normal to \( S \) is directed along the coordinate basis vector dual to \( dr \) and has components
\[
n_\mu = \delta^1_\mu e^{\lambda/2}. \quad (B.1)
\]

The metric components \( \gamma_{\mu\nu} \) in \( U \) and \( \bar{\gamma}_{\mu\nu} \) in \( \bar{U} \) are given by Eqs. (2.2), (3.20) and (3.21). The first fundamental form of \( S \) has components \( \gamma_{ij} = \bar{\gamma}_{ij} \). The second fundamental form \( K_{\mu\nu} \equiv n_{\mu\nu} \) of any hypersurface \( r = \text{constant} \) has components
\[
K_{ij} = \eta_{\alpha;\beta} \frac{\partial x^\alpha}{\partial u^i} \frac{\partial x^\beta}{\partial u^j} = -\Gamma^1_{ij} e^{\lambda/2} \quad (B.2)
\]
in coordinates \( \{u^i\} \). Using the Christoffel symbols of a spherically symmetric metric (see e.g. [25]), we obtain the only nonvanishing components
\[
K_{00} = -\frac{\nu'}{2} e^{\nu - \lambda/2}, \quad (B.3)
\]
\[ K_{22} = r e^{-\lambda/2}, \quad (B.4) \]
\[ K_{33} = r e^{-\lambda/2} \sin^2 \theta. \quad (B.5) \]

The Darmois conditions [28] require the continuity of the first and second fundamental form across \( S \). The first condition is trivially satisfied, while the second is violated. In fact, we have

\[
\begin{align*}
\lim_{r \to a^-} K_{00} &= 0 \neq \lim_{r \to a^+} K_{00} = -\frac{16}{27 M}, \quad (B.6) \\
\lim_{r \to a^-} K_{22} &= a \neq \lim_{r \to a^+} K_{22} = \frac{a}{3}, \quad (B.7) \\
\lim_{r \to a^-} K_{33} &= a \sin^2 \theta \neq \lim_{r \to a^+} K_{33} = \frac{a}{3} \sin^2 \theta, \quad (B.8)
\end{align*}
\]

where the BH relation \( a = 9M/4 \) was used.

**Appendix C: Dominant order in \( R_{\alpha \beta}^{(1)} \)**

The second covariant derivatives appearing in Eq. (2.16) are

\[
\begin{align*}
\gamma_{\mu \nu \lambda \beta} &= h_{\mu \nu \lambda \beta} - \Gamma^\sigma_{\alpha \beta} h_{\mu \nu \sigma} - \Gamma^\sigma_{\beta \mu} h_{\sigma \nu \alpha} - \Gamma^\sigma_{\alpha \mu} h_{\sigma \nu \beta} - \Gamma^\sigma_{\alpha \nu} h_{\sigma \mu \beta} - \Gamma^\sigma_{\beta \nu} h_{\sigma \mu \alpha} - \Gamma^\sigma_{\mu \alpha} h_{\sigma \nu \beta} \\
+ \Gamma_{\alpha \beta \gamma} \Gamma^\gamma_{\mu \nu \sigma} h_{\rho \rho} + \Gamma_{\beta \mu \gamma} \Gamma^\gamma_{\alpha \nu \sigma} h_{\rho \rho} + \Gamma_{\gamma \nu \sigma} \Gamma^\sigma_{\alpha \mu \rho} h_{\rho \rho} - \Gamma_{\gamma \nu \sigma} \Gamma^\sigma_{\alpha \mu \rho} h_{\rho \rho} \\
- \Gamma_{\alpha \beta \gamma} \Gamma^\gamma_{\mu \nu \sigma} h_{\rho \rho} + \Gamma_{\alpha \beta \gamma} \Gamma^\gamma_{\mu \nu \sigma} h_{\rho \rho} + \Gamma_{\beta \mu \gamma} \Gamma^\gamma_{\alpha \nu \sigma} h_{\rho \rho} + \Gamma_{\gamma \nu \sigma} \Gamma^\sigma_{\alpha \mu \rho} h_{\rho \rho} + \Gamma_{\gamma \nu \sigma} \Gamma^\sigma_{\alpha \mu \rho} h_{\rho \rho}. \quad (C.1)
\end{align*}
\]

Symbolically, we express the various quantities in the last equation as follows:

\[
\begin{align*}
\Gamma &= \gamma \partial \gamma = O(1), \quad (C.2) \\
\gamma \partial h &= O(1), \quad (C.3) \\
(\partial \gamma) h &= O(\epsilon), \quad (C.4) \\
h \partial h &= O(\epsilon), \quad (C.5) \\
\Delta h &= O(1), \quad (C.6) \\
(\partial \Gamma) h &= O(\epsilon), \quad (C.7) \\
\Gamma \Gamma h &= O(\epsilon). \quad (C.8)
\end{align*}
\]

By using Eqs. (C.2)–(C.8) in (C.1) and then, in conjunction with Eq. (2.16), Eq. (4.1) follows. The quantity \( (h_{\rho \nu \alpha \beta} + h_{\alpha \beta \rho \gamma} - h_{\gamma \alpha \beta \rho} - h_{\gamma \beta \alpha \rho}) \) in Eq. (4.1) contains terms of order \( O(1/\epsilon) \) as well as terms of order \( O(1) \). We retain only the former ones in the linearized Einstein equations to order \( O(1/\epsilon) \).
Appendix D: Angle average of $T^\nu_\mu$ in the high frequency limit

Equations (4.14)–(4.16) includes integrating over the angle $\varphi$ and dividing by the solid angle $4\pi$, thus all that is left is evaluating the $\theta$ integrals (see Ref. [1]). The $\theta$ dependence of $T^\nu_\mu$ comes in three forms

$$\sin^{-2} \theta \left( \Theta^l(\theta) \right)^2, \sin^{-2} \theta \left( \Theta^l(\theta)\theta \right)^2 \text{ and } \sin^{-2} \theta \Theta^l(\theta)\Theta^l(\theta)_{22}.$$  \hspace{1cm} (D.1)

where

$$\Theta^l(\theta) = C^{l0} B^l(\theta) \hspace{1cm} \text{(D.2)}$$

and

$$B^l(\theta) \equiv \sin \theta \frac{d}{d\theta} P^l(\cos \theta). \hspace{1cm} \text{(D.3)}$$

The exact integrals are evaluated below with the last equality being the value used for the high frequency approximation:

$$\int_0^\pi \sin^{-2} \theta \left( B^l(\theta) \right)^2 \sin \theta d\theta = \frac{2l(l+1)}{2l+1} \approx l, \hspace{1cm} (D.4)$$

$$\int_0^\pi \sin^{-2} \theta \left( B^l(\theta)\theta \right)^2 \sin \theta d\theta = \frac{2l^2(l+1)^2}{2l+1} \approx l^3, \hspace{1cm} (D.5)$$

$$\int_0^\pi \sin^{-2} \theta B^l(\theta) B^l(\theta)_{00} \sin \theta d\theta = -\frac{2l^3(l+1)}{2l+1} \approx -l^3. \hspace{1cm} (D.6)$$

The normalization constant for $\Theta^l(\theta)$ is found by requiring

$$\int_0^{2\pi} \int_0^\pi \left| \Theta^l(\theta) \right|^2 \sin \theta d\theta d\varphi = 1. \hspace{1cm} (D.7)$$

Therefore

$$\left[ C^{l0} \right]^2 = \frac{1}{2\pi} \left[ \int_0^\pi \left( B^l(\theta) \right)^2 \sin \theta d\theta \right]^{-1} = \frac{1}{2\pi} \left[ \frac{4l^2(l+1)^2}{(2l-1)(2l+1)(2l+3)} \right]^{-1}. \hspace{1cm} (D.8)$$

Thus the normalization constant is

$$C^{l0} = \left[ \frac{(2l-1)(2l+1)(2l+3)}{8\pi l(l+1)^2} \right]^{1/2} \approx \frac{1}{\sqrt{\pi l}}. \hspace{1cm} (D.9)$$

Fig. 1 Results of the numerical integration for the gravitational geon differential equations (Eqs. (4.45)–(4.47)). The integration was performed from $x = -4$ to $x = 35$ with initial condition $\phi(-4) \equiv \phi_0 = 1.0 \times 10^{-4}$. The active region denoted by the region where the factor $j(x) k(x)$ is positive extends from approximately $x = 0$ to $\infty$. Consequently $\phi(x)$ oscillates out to $\infty$ and the mass of the gravitational geon (proportional to $(1-k^2)$) is negative for all $x$. Other values of $\phi_0$ do not qualitatively change the behaviour of the functions $\phi(x)$, $j(x)$ or $k(x)$.

Fig. 2 Results of the numerical integration for the electromagnetic geon differential equations (Eqs. (4.54)–(4.56)). The initial value of $\phi(-4)$ was $\phi_0 = 9.790419490 \times 10^{-5}$. The integration started at $x = -4$ and could not proceed beyond approximately $x = 11$. The active region began at approximately $x = 0.1$ and ended at $x = 0.2$. Note that $\phi(x)$ exhibits singular behaviour at approximately $x = 11$.

Fig. 3 Results of the numerical integration for an electromagnetic geon with an initial value of $\phi_0 = 9.790419489 \times 10^{-5}$. For this case, $\phi(x)$ approaches $-\infty$ at approximately $x = 11$.
