Abstract

In this paper we express the velocity dependent, spin dependent heavy quark potential $V_{q\bar{q}}$ in QCD in terms of a Wilson Loop $W(\Gamma)$ determined by pure Yang Mills theory. We use an effective dual theory of long-distance Yang Mills theory to calculate $W(\Gamma)$ for large loops; i.e. for loops of size $R > R_{FT}$. ($R_{FT}$ is the flux tube radius, fixed by the value of the Higgs (monopole) mass of the dual theory, which is a concrete realization of the Mandelstam 't Hooft dual superconductor mechanism of confinement). We replace $W(\Gamma)$ by $W_{\text{eff}}(\Gamma)$, given by a functional integral over the dual variables, which for $R > R_{FT}$ can be evaluated by a semiclassical expansion, since the dual theory is weakly coupled at these distances. The classical approximation gives the leading contribution to $W_{\text{eff}}(\Gamma)$ and yields a velocity dependent heavy quark potential which for large $R$ becomes linear in $R$, and which for small $R$ approaches lowest order perturbative QCD. This latter fact means that these results should remain applicable down to distances where radiative corrections giving rise to a running coupling constant become important. The spin dependence of the potential reflects the vector coupling of the quarks at long range as well as at short range. The methods developed here should be applicable to any realization of the dual superconductor mechanism. They give an expression determining $W_{\text{eff}}(\Gamma)$ independent of the classical approximation, but semi classical corrections due to fluctuations of the flux tube are not worked out in this paper. Taking these into account should lead to an effective string theory free from the conformal anomaly.
1 Introduction

In this paper we give expressions for the heavy quark potential in QCD using an effective dual theory of long distance Yang–Mills theory. This work goes beyond a previous treatment\textsuperscript{[1]} where the quark motion was treated semi-classically and where the dual theory was considered only at the classical level, and provides an independent approach to the problem of the heavy quark potential.

In Section two we give the formulae for the heavy quark spin dependent velocity dependent potential $V_{q\bar{q}}$ obtained in refs. $^[2,3,4]$ in terms of a Wilson loop $W(\Gamma)$. This expression extends previous work of Eichten and Feinberg,$^[6]$ Peskin$^[6]$, Gromes and others$^[6]$ to include the velocity dependent spin independent part of the potential. The problem of the heavy quark potential is then reduced to the problem of calculating $W(\Gamma)$ in pure Yang–Mills theory. All momenta, spins, masses and quantum mechanical properties of the quarks appear explicitly in the formulae$^[2]$ relating $V_{q\bar{q}}$ to $W(\Gamma)$. The size of the loop $\Gamma$ fixed by the classical trajectories of the moving quark-antiquark pair provides a length scale $R$ (the quark-antiquark separation) and we use the dual theory to evaluate $W(\Gamma)$ for $R > R_{FT}$, the radius of the flux tube that forms between the moving quark antiquark pair.

In Section three we describe the dual theory and then show how to calculate the Wilson loops of Yang Mills theory at long distances (large loops). This is done by replacing $W(\Gamma)$ by $W_{\text{eff}}(\Gamma)$, a functional integral over dual potentials $C_\mu$ which are the fundamental variables of the dual theory. We then obtain the spin independent part of the heavy quark potential directly in terms of $W_{\text{eff}}(\Gamma)$. Finally we discuss the relation of the dual theory to recent work$^[7,8]$ on the use of electric-magnetic duality to determine the long distance behavior of certain supersymmetric non-Abelian gauge theories.

In Section four we give explicit expressions for the spin dependent part of the heavy quark potential in terms of quantities determined by the dual theory. Since the theory is weakly coupled at large distances, $W_{\text{eff}}(\Gamma)$ and hence $V_{q\bar{q}}$ can be evaluated by a semiclassical expansion.

1
In Section five we calculate $W_{\text{eff}}(\Gamma)$ in the classical approximation to the dual theory. We show how these results yield the dual superconducting picture of confinement and discuss their relation to the “modified area law” model for $W(\Gamma)$, proposed in ref.\cite{9}. Finally we remark how recent progress on quantization around classical vortex solutions\cite{10} may be useful for calculating corrections to $W_{\text{eff}}(\Gamma)$ accounting for fluctuations of the length of the flux tube.

In Section six we use the results of Section four and the classical solution to the dual theory to obtain the spin dependent part of the heavy quark potential. This calculation gives a contribution to $V_{q\bar{q}}$ not obtained previously\cite{11} and yields a simplified expression for the spin orbit potential which reflects the vector nature of both the short range force and the confinement force.

In the conclusion we point out that the results presented here should be regarded more as consequences of the dual superconductor picture in general rather than of our particular realization of it.\cite{12}

2 The Heavy Quark Potential in QCD

To obtain the heavy quark potential $V_{q\bar{q}}$ we\cite{2} make a Foldy Wouthuysen transformation on the quark-antiquark Green’s function and show that the result can be written as a Feynman path integral over particle and anti-particle coordinates and momenta of a Lagrangian depending only upon the spin, coordinates, and momenta of the quark and antiquark. Separating off the kinetic terms from this Lagrangian one can identify what remains as the heavy quark potential $V_{q\bar{q}}$. (Closed loops of light quark pairs and annihilation contributions were not included.)

The terms in $V_{q\bar{q}}$ of order (quark mass)$^{-2}$ are of two types; velocity dependent $V_{VD}$ and spin dependent $V_{SD}$. The full potential $V_{q\bar{q}}$ is then

$$m(2.1) \quad V_{q\bar{q}} = V_0(R) + V_{VD} + V_{SD},$$

where $V_0(R)$ is the static potential. These potentials are all expressed in terms of a Wilson
Loop $W(\Gamma)$ determined by pure Yang-Mills theory, given by

$$W(\Gamma) = \frac{\int D A e^{iS_{YM}(A)} tr P \exp(-i e \int_{\Gamma} dx^{\mu} A_{\mu}(x))}{\int D A e^{iS_{YM}(A)}}.$$ \hfill (m.2.2)

The closed loop $\Gamma$ is defined by quark (anti-quark) trajectories $\tilde{z}_1(t)(\tilde{z}_2(t))$ running from $\tilde{y}_1$ to $\tilde{x}_1(\tilde{x}_2)$ as $t$ varies from the initial time $t_i$ to the final time $t_f$. The quark (anti-quark) trajectories $\tilde{z}_i(t)(\tilde{z}_2(t))$ define world lines $\Gamma_i(\Gamma_2)$ running from $t_i$ to $t_f(t_f$ to $t_i)$. The world lines $\Gamma_1$ and $\Gamma_2$, along with two straight lines at fixed time connecting $\tilde{y}_1$ to $\tilde{y}_2$ and $\tilde{z}_1$ to $\tilde{z}_2$, then make up the contour $\Gamma$ (see Fig.1). As usual $A_{\mu}(x) = \frac{1}{2} \lambda \sigma A_\mu(x)$, $tr$ means the trace over color indices, $P$ prescribes the ordering of the color matrices according to the direction fixed on the loop and $S_{YM}(A)$ is the Yang-Mills action including a gauge fixing term. We have denoted the Yang-Mills coupling constant by $\alpha$, i.e.,

$$\alpha_s = \frac{e^2}{4\pi}.$$ \hfill (m.2.3)

The spin independent part of the potential, $V_0 + V_{V,D}$, is obtained from the zero order and the quadratic terms in the expansion of $i \log W(\Gamma)$ for small velocities $\dot{\tilde{z}}_1(t)$ and $\dot{\tilde{z}}_2(t)$. This expansion has the form:

$$i \log W(\Gamma) = \int_{t_i}^{t_f} dt \left( V_0(\vec{R}(t)) + \sum_{i,j=1}^{2} \sum_{k,l=1}^{3} \dot{z}_i^k(t)V_{ij}^{kl}(\vec{R}(t))\dot{z}_j^l(t) \right).$$ \hfill (m.2.4)

where $\vec{R}(t) = \vec{z}_1(t) - \vec{z}_2(t)$, and

$$V_{V,D} = \sum_{i,j=1}^{2} \sum_{k,l=1}^{3} \dot{z}_i^k(t)V_{ij}^{kl}(\vec{R}(t))\dot{z}_j^l(t).$$ \hfill (m.2.5)

($i \log W(\Gamma)$ has an expansion of the form (2.4) only to second order in the velocities.) The expression (2.5) for $V_{V,D}$ follows from the same argument used to identify $V_0(R)$ as the velocity independent term in the expansion (2.4). We can write eq. (2.4) in the form

$$i \log W(\Gamma) = -\int_{t_i}^{t_f} dt \mathcal{L}_I(z_1, z_2, \dot{z}_1, \dot{z}_2),$$ \hfill (m.2.6)

where

$$-\mathcal{L}_I = V_0(R) + V_{V,D}$$ \hfill (m.2.7)
is an effective interaction Lagrangian for classical particles moving along trajectories $\bar{z}_1(t)$ and $\bar{z}_2(t)$ with gauge couplings $e(-e)$ and we can then interpret $i \log W(\Gamma)$ as an effective action describing the motion of classical particles after elimination of the Yang–Mills field.

The spin dependent potential $V_{SD}$ contains structures for each quark analogous to those obtained by making a Foldy Wouthuysen transformation on the Dirac equation in an external field $F_{\mu\nu}^{EXT}$, along with an additional term $V_{SS}$ having the structure of a spin–spin interaction. We can then write

\begin{equation}
V_{SD} = V_{LS}^{MAG} + V_{Thomas} + V_{Darwin} + V_{SS},
\end{equation}

using a notation which indicates the physical significance of the individual terms (MAG denotes magnetic). The first two terms in eq. (2.8) can be obtained by making the replacement

\begin{equation}
F_{\mu\nu}^{EXT}(x) \rightarrow \langle \langle F_{\mu\nu}(x) \rangle \rangle,
\end{equation}

in the corresponding expression for the interaction of a Dirac particle in an external field, where

\begin{equation}
\langle \langle f(A) \rangle \rangle \equiv \frac{\int D \! A e^{iS_{YM}(A)} tr P \{\exp[-ie\oint F_{\mu\nu}^{EXT}(x)] f(A)\}}{\int D \! A e^{iS_{YM}(A)} tr P \exp[-ie\oint F_{\mu\nu}^{EXT}(x)]},
\end{equation}

and

\begin{equation}
F_{\mu\nu} = \partial_{\mu}A_{\nu} - \partial_{\nu}A_{\mu} - ie[A_{\mu}, A_{\nu}],
\end{equation}

i.e. $\langle \langle F_{\mu\nu}(x) \rangle \rangle$ is the expectation of the Yang–Mills field tensor in the presence of a quark and anti–quark moving along classical trajectories $\bar{z}_1(t)$ and $\bar{z}_2(t)$ respectively.

The explicit expressions for $V_{LS}^{MAG}$ and $V_{Thomas}$ obtained in ref.[2] are\(^3\)

\begin{equation}
\int dt V_{LS}^{MAG} = \sum_{j=1}^{2} \frac{e}{m_j} \int_{\Gamma_j} dx^\tau S^j_\tau \langle \langle \hat{F}_{\mu\nu}(x) \rangle \rangle,
\end{equation}

\(^3\)Here and in the following $\int_{\Gamma_j} dx^\mu f_\mu(x) \equiv (-1)^{j+1} \int_{z_j}^{z_{j+1}/2} dt (f_0(z_j) - \tilde{z}_j \cdot \tilde{f}(z_j))$, where $z_j = (t, \bar{z}_j(t))$. The factor $(-1)^{j+1}$ accounts for the fact that world line $\Gamma_2$ runs from $t_f$ to $t_i$. We also use the notation $z_j' = (t', \bar{z}_j(t'))$. 

\[\text{Page } 4\]
and
\[ m(2.13) \quad \int dt V_{\text{Thomas}} = -\sum_{j=1}^{2} \frac{e}{2m_j^2} \int_{\Gamma_j} dx^\mu \hat{S}_j^\mu \epsilon^\nu \hat{F}_j^\nu \langle \langle F_{\mu\nu}(x) \rangle \rangle, \]
where
\[ m(2.14) \quad \hat{F}_{\mu\nu} = \frac{1}{2} \epsilon_{\mu\nu\rho\sigma} F^{\rho\sigma}, \]
\( \hat{S}_j \) is the spin matrix, and \( m_j \) is the mass of the \( j \)th quark. Because the expression for \( V_{\text{Thomas}} \) contains an explicit factor of \( \frac{1}{m_j^2} \), the integral over the trajectory of the \( j \)th quark \( \int_{\Gamma_j} dx^\mu \langle \langle F_{\mu\nu}(x) \rangle \rangle \) can be replaced by \( (-1)^{j+1} \int_{\Gamma_j} dt \langle \langle F_{\nu\sigma}(z_j) \rangle \rangle \) evaluated for static quarks. This gives the usual expression for \( V_{\text{Thomas}} \) in terms of the derivative of the central potential (see Section four). The expression for \( V_{\text{LS}}^{\text{MAG}} \) on the other hand contains only a single power of \( \frac{1}{m_j} \) and \( \int_{\Gamma_j} dx^\sigma \langle \langle \hat{F}_{\nu\sigma}(x) \rangle \rangle \) must be evaluated to first order in the quark velocities. There results the usual magnetic interaction of the spin of the \( j \)th quark with the expectation value \( \langle \langle \hat{F}_{\nu\sigma}(z_j) \rangle \rangle \).

The expression for \( V_{\text{Darwin}} \) is
\[ m(2.15) \quad \int dt V_{\text{Darwin}} = -\sum_{j=1}^{2} \frac{e}{8m_j^2} \int_{\Gamma_j} dx^\mu \langle \langle D^\nu F_{\nu\mu}(x) \rangle \rangle, \]
where
\[ m(2.16) \quad D^\nu F_{\nu\mu} = \partial^\nu F_{\nu\mu} - ie [A^\nu, F_{\nu\mu}], \]
Again because of the explicit factor of \( \frac{1}{m_j^2} \), the integral over the trajectory \( \Gamma_j \) of the \( j \)th quark is evaluated for static quarks.

The final term \( V_{SS} \) in eq. (2.8) is given by
\[ \int V_{SS} dt = -\frac{1}{2} \sum_{j,j'=1}^{2} \frac{ie^2}{m_jm_{j'}} T_s \int_{\Gamma_j} dx^\mu \int_{\Gamma_j} dx'^\sigma \hat{S}_j^\mu \hat{S}_j'^{\sigma}, \]
\[ m(2.17) \quad (\langle \langle \hat{F}_{\mu\nu}(x) \hat{F}_{\kappa\sigma}(x') \rangle \rangle - \langle \langle \hat{F}_{\mu\nu}(x) \rangle \rangle \langle \langle \hat{F}_{\kappa\sigma}(x') \rangle \rangle), \]
where \( T_s \) is the spin time ordering operator along the paths \( \Gamma_1 \) and \( \Gamma_2 \), and the averages are evaluated for static quarks. The terms \( j \neq j' \) in eq. (2.17) give a spin-spin interaction
proportional to $1/m_1 m_2$ while the terms $j = j'$ in eq. (2.17) give a spin independent term proportional to $(1/m_1^2 + 1/m_2^2)$. The spin ordering is relevant only for these latter terms.

We have thus obtained the explicit expression (2.8) for the spin dependent potential as a sum of terms depending upon the quark and antiquark spins, masses and momenta with coefficients which are expectation values $\langle \rangle$ of operators computed in Yang–Mills theory in presence of classical sources generated by the moving quark-antiquark pair. We now show that these expectation values can be obtained as functional derivatives of $i \log W(\Gamma)$ with respect to the path, i.e., with respect to the trajectories $\bar{z}_1(t)$ or $\bar{z}_2(t)$. For example consider the change in $W(\Gamma)$ induced by letting

$$\bar{z}_1(t) \to \bar{z}_1(t) + \delta \bar{z}_1(t), \text{ where } \delta \bar{z}_1(t_i) = \delta \bar{z}_1(t_f) = 0.$$ 

Then from the definitions (2.2) and (2.10), it follows that

$$\delta i \log W(\Gamma) = -e \int_{t_i}^{t_f} \frac{\delta S^{\mu\nu}(z_1)}{2} \langle [F_{\mu\nu}(z_1)] \rangle,$$

where

$$\delta S^{\mu\nu}(z_1) = (dz_1^{\mu} \delta z_1^{\nu} - dz_1^{\nu} \delta z_1^{\mu}).$$

Eq. (2.18) then gives

$$-e \langle [F_{\mu\nu}(z_1)] \rangle = \frac{\delta i \log W(\Gamma)}{\delta S^{\mu\nu}(z_1)},$$

and similarly one can get

$$e \langle [F_{\mu\nu}(z_2)] \rangle = \frac{\delta i \log W(\Gamma)}{\delta S^{\mu\nu}(z_2)}.$$

Varying the path $\bar{z}_2(t)$ in eq. (2.20) gives

$$e^2 \left( \langle [F_{\mu\nu}(z_1) F_{\rho\sigma}(z_2)] \rangle - \langle [F_{\mu\nu}(z_1)] \rangle \langle [F_{\rho\sigma}(z_2)] \rangle \right) = ie \frac{\delta}{\delta S^{\rho\sigma}(z_2)} \langle [F_{\mu\nu}(z_1)] \rangle.$$

The first and second variational derivatives of $W(\Gamma)$ then determine the expectation values of $F_{\mu\nu}$ needed to evaluate $V_{SD}$. Furthermore, we show in an appendix that $\langle [D^{\nu} F_{\nu\mu}(x)] \rangle$ appearing in $V_{Darwin}$ can also be expressed in terms of variational derivatives of $W(\Gamma)$. The
Wilson loop $W(\Gamma)$ which is determined by pure Yang–Mills theory then fixes the complete heavy quark potential $V_{q\bar{q}}$. Thus, up to order $\left(\frac{1}{\text{quark mass}}\right)^2$ the dynamics of a quark anti-quark pair in QCD is completely fixed by the dynamics of Yang–Mills theory. The properties of the quark spins, masses, etc., appear only as given kinematic factors in the terms defining the heavy quark potential.

The result (2.8) for $V_{SD}$ is a consequence of the vector nature of the QCD interaction and contains precisely the same dependence upon the quarks spins, masses, and momenta as in QED. For example in eqs. (2.12) and (2.13) there is the usual vector coupling of quarks to $\langle F_{\mu\nu}(x) \rangle$. The long (short) range part of $V_{SD}$ is determined by the behavior of this field at long (short) distances. Both have the same vector coupling.

This expansion as it stands is applicable only to calculating the potential between heavy quarks. The essence of the constituent quark model is that the same potential can also be used to calculate the energy levels of mesons containing light quarks with constituent masses fixed by hadron spectroscopy. The assumption is that the principal effect of the light quark dynamics can be accounted for by giving the light quarks effective masses which become the parameters of the constituent quark model.

Finally we note the following "modified area law" proposed in ref.[9]: $i \log W(\Gamma)$ is written as the sum of a short range (SR) contribution and a long range (LR) one:

\[ i \log W(\Gamma) = i \log W^{SR}(\Gamma) + i \log W^{LR}(\Gamma), \]

with $i \log W^{SR}(\Gamma)$ given by ordinary perturbation theory and

\[ i \log W^{LR}(\Gamma) = \sigma S_{\text{min}}, \]

where $S_{\text{min}}$ is the minimal surface enclosed by the loop $\Gamma$ and $\sigma$ is the string tension. We will see in Section five the relation of this ansatz to the predictions of the dual theory.
3 The Dual Description of Long Distance Yang-Mills Theory

The dual theory is an effective theory of long distance Yang–Mills theory described by a Lagrangian density $\mathcal{L}_{\text{eff}}$ in which the fundamental variables are an octet of dual potentials $C_\mu$ coupled minimally to three octets of scalar Higgs fields $B_i$ carrying magnetic color charge. (The gauge coupling constant of dual theory $g = \frac{2\pi}{e}$ where $e$ is the Yang–Mills coupling constant.) The monopole fields $B_i$ develop non-vanishing vacuum expectation values $B_{0i}$ (monopole condensation) which give rise to massive $C_\mu$ and consequently to a dual Meissner effect. Dual potentials couple to electric color charge like ordinary potentials couple to monopoles. The potentials $C_\mu$ thus couple to a quark anti-quark pair via a Dirac string connecting the pair. The dual Meissner effect prevents the electric color flux from spreading out as the distance $R$ between the quark anti-quark pair increases. As a result a linear potential develops which confines the quarks in hadrons. The dual theory then provides a concrete realization of the Mandelstam 't Hooft dual superconductor picture of confinement.

Because the quanta of the potentials $C_\mu$ are massive, the dual theory is weakly coupled at distances $R > \frac{1}{M}$ ($M$ being either the mass of the dual gluon or of the monopole field) and a semi-classical expansion can be used to calculate the heavy quark potential at those distances. The classical approximation gives the leading contribution to functional integrals defined by $\mathcal{L}_{\text{eff}}$, in contrast to the functional integrals of Yang–Mills theory where no single configuration of gauge potentials dominates $W(\Gamma)$. The duality assumption that the long distance physics of Yang–Mills theory depending upon strongly coupled gauge potentials $A_\mu$ is the same as the long distance physics of the dual theory describing the interactions of weakly coupled dual potentials $C_\mu$ and monopole fields $B_i$ forms the basis of the work of this paper.

Before writing down the explicit form of $\mathcal{L}_{\text{eff}}$, we first show how to calculate $W(\Gamma)$ for Abelian Gauge theory using the dual description of electrodynamics$^{[14]}$, which describes the same physics as the original description at all distances. We consider a pair of particles with
charges $e(-e)$ moving along trajectories $\vec{z}_1(t)(\vec{z}_2(t))$ in a relativistic medium having dielectric constant $\epsilon$. The current density $j^\mu(x)$ then has the form

$$j^\mu(x) = e \int_\Gamma dz^\mu \delta(x - z),$$

where $\Gamma$ is the world line described in fig.1. In the usual $A_\mu$ (electric) description this system is described by a Lagrangian

$$\mathcal{L}_A(j) = -\frac{e}{4}(\partial_\alpha A_\beta - \partial_\beta A_\alpha)^2 - j^\alpha A_\alpha,$$

from which one obtains the usual Maxwell equations

$$\partial^\alpha e(\partial_\alpha A_\beta - \partial_\beta A_\alpha) = j_\beta.$$

If the (wave number dependent) dielectric constant $\epsilon \to 0$ at long distances, then we see from eq. (3.3) that $A_\mu$ is strongly coupled at long distances (anti-screening). From (3.1) and (3.2) we have

$$\int dx \mathcal{L}_A(j) = -\int dx \frac{e(\partial_\mu A_\nu - \partial_\nu A_\mu)^2}{4} - e \int_\Gamma dz^\mu A_\mu(z).$$

The functional integral defining $W(\Gamma)$ in Abelian gauge theory

$$W(\Gamma) = \frac{\int D\!A_\mu e^{i \int dx [\mathcal{L}_A(j) + \mathcal{L}_{GF}]} \int D\!A_\mu e^{i \int dx [\mathcal{L}_A(j=0) + \mathcal{L}_{GF}]}}{\int D\!A_\mu e^{i \int dx [\mathcal{L}_A(j=0) + \mathcal{L}_{GF}]}};$$

where $\mathcal{L}_{GF}$ is a gauge fixing term, is gaussian and has the value

$$W(\Gamma) = e^{\frac{i}{2} \int_\Gamma dx^\mu \int_{\Gamma'} dx'^\nu D_{\mu\nu}(x-x')},$$

where $D_{\mu\nu}$ is the free photon propagator and where self energies have been subtracted. Because of current conservation the result (3.6) is independent of the choice of gauge. Letting $\epsilon = 1$ and expanding $i \log W(\Gamma)$ to second order in the velocities, as in eq. (2.4), gives the Darwin Lagrangian $L_D$ describing the interaction of a pair of oppositely charged particles

$$L_D = \frac{e^2}{4\pi R} - \frac{1}{2} \frac{e^2}{4\pi R} \left[ \vec{v}_1 \cdot \vec{v}_2 + \frac{(\vec{v}_1 \cdot \vec{R})(\vec{v}_2 \cdot \vec{R})}{R^2} \right].$$
In the dual description we consider first the inhomogeneous Maxwell equations, which we write in the form:

\[ m(3.8) \quad -\partial^\beta \varepsilon^\alpha_{\beta \sigma \lambda} G^\sigma_{\lambda} = j_\alpha, \]

where \( G_{\mu \nu} \) is the dual field tensor composed of the electric displacement vector \( \tilde{D} \) and the magnetic field vector \( \tilde{H} \):

\[ m(3.9) \quad G_{0k} \equiv H_k, \quad G_{\ell m} = \varepsilon_{\ell mn} D^n. \]

Next we express the charged particle current in eq. (3.8) as the divergence of a polarization tensor \( G^S_{\mu \nu} \), the Dirac string tensor, representing a moving line of polarization running from the negatively charged to the positively charged particle, namely \( \text{[14]} \)

\[ m(3.10) \quad G^S_{\mu \nu}(x) = -\varepsilon_{\mu \nu \alpha \beta} \int d\sigma \int d\tau \frac{\partial y^\alpha}{\partial \sigma} \frac{\partial y^\beta}{\partial \tau} \delta(x - y(\sigma, \tau)), \]

where \( y^\alpha(\sigma, \tau) \) is a world sheet with boundary \( \Gamma \) swept out by the Dirac string. Then \( \text{[1]} \)

\[ m(3.11) \quad -\partial^\beta \varepsilon^\alpha_{\beta \sigma \lambda} G^S_{\sigma \lambda}(x) = j_\alpha(x) \]

and the solution of eq. (3.8) is

\[ m(3.12) \quad G_{\mu \nu} = \partial_\mu C_\nu - \partial_\nu C_\mu + G^S_{\mu \nu}, \]

which defines the magnetic variables (the dual potentials \( C_\mu \)). (With eqs. (3.11) and (3.12) the inhomogeneous Maxwell equations become Bianchi identities.)

The homogeneous Maxwell equations for \( \tilde{E} \) and \( \tilde{B} \), which we write in the form

\[ m(3.13) \quad \partial^\alpha (\mu C_{\alpha \beta}) = 0, \]

where \( \mu = \frac{1}{\varepsilon} \) is the magnetic susceptibility, now become dynamical equations for the dual potentials. These equations can be obtained by varying \( C_\mu \) in the Lagrangian

\[ m(3.14) \quad \mathcal{L}_C(G^S_{\mu \nu}) = -\frac{1}{4} \mu G^S_{\mu \nu} G^{\mu \nu}, \]
where $G_{\mu\nu}$ is given by eq. (3.12). This Lagrangian provides the dual (magnetic) description of the Maxwell theory (3.2). In the dual description the Wilson loop $W(\Gamma)$ is given by

$$W(\Gamma) \equiv \frac{\int DC_\mu e^{i \int dx [\mathcal{L} C_\mu + \mathcal{L}_{\alpha\beta}]]}}{\int DC_\mu e^{i \int dx [\mathcal{L} C_\mu = 0 + \mathcal{L}_{\alpha\beta}]]}}.$$ \hfill (m.3.15)

Evaluating the functional integral (3.15) by completing the square gives

$$W(\Gamma) = e^{-\frac{1}{\mu} \int dx G_{\alpha\beta}(x) G_{\alpha\beta}(x)},$$ \hfill (m.3.16)

where $G_{\alpha\beta}(x)$ is the dual field tensor (3.12) with $C_\mu = C_\mu^D$ determined from the solution of eq. (3.13), which has the explicit form

$$\partial_\alpha \mu (\partial_\alpha C_\beta^D - \partial_\beta C_\alpha^D) = -\partial_\alpha \mu G_{\alpha\beta}^S.$$ \hfill (m.3.17)

Inserting

$$G_{\alpha\beta}(x) = -\frac{1}{2} \varepsilon_{\alpha\beta\lambda\sigma} \partial_\lambda \int dy D_{\sigma\beta}(x - y) j_\sigma(y) - \partial_\sigma \int dy D_{\lambda\beta}(x - y) j_\lambda(y)),$$ \hfill (m.3.18)

into (3.16), integrating by parts, and using eq. (3.11), we obtain the same result (eq. (3.6) with $\frac{1}{\varepsilon} \rightarrow \mu$) for the Wilson loop (3.15) defined in the magnetic description as we had obtained for the Wilson loop defined in the electric description. We then have two equivalent descriptions at all distances of the electromagnetic interaction of two charged particles. (Note, however, that if $\varepsilon \rightarrow 0$ at long distances, then $\mu \rightarrow \frac{1}{\varepsilon} \rightarrow \infty$ and the dual potentials $C_\mu$ determined from eq. (3.13) are not strongly coupled at long distances unlike the potentials $A_\mu$ determined from eq. (3.3).)

We now return to $L_{\text{eff}}$, which in absence of quark sources has the form\(^{[1]}\)

$$L_{\text{eff}} = 2tr \left[ -\frac{1}{4} G^{\mu\nu} G_{\mu\nu} + \frac{1}{2} (D_\mu B_i)^2 \right] - W(B_i),$$ \hfill (m.3.19)

where

$$D_\mu B_i = \partial_\mu B_i - ig[C_\mu, B_i],$$ \hfill (m.3.20)

$$G_{\mu\nu} = \partial_\mu C_\nu - \partial_\nu C_\mu - ig[C_\mu, C_\nu],$$ \hfill (m.3.21)
\( g = \frac{2\pi}{e}, \)

\( C_\mu \) and \( B_i \) are \( SU(3) \) matrices, and \( W(B_i) \) is the Higgs potential which has a minimum at non-zero values \( B_{0i} \) which have the color structure

\[
\begin{align*}
  m(3.22) \quad B_{01} &= B_0 \lambda_7, \quad B_{02} = B_0(-\lambda_5), \quad B_{03} = B_0 \lambda_2. \\

  \text{The three matrices } \lambda_7, -\lambda_5 \text{ and } \lambda_2 \text{ transform as a } j = 1 \text{ irreducible representation of an} \\
  \text{SU(2) subgroup of SU(3) and as there is no SU(3) transformation which leaves all three} \\
  \text{B}_{0i} \text{ invariant the dual SU(3) gauge symmetry is completely broken and the eight Goldstone} \\
  \text{bosons become the longitudinal components of the now massive } C_\mu. \\

  \text{The basic manifestation of the dual superconducting properties of } \mathcal{L}_{\text{eff}} \text{ is that it generates classical equations of motion having solutions}^{[17]} \text{ carrying a unit of } Z_3 \text{ flux confined} \\

  \text{(These solutions are dual to Abrikosov–Nielsen–Olesen magnetic vortex solutions}^{[18]} \text{ in a superconductor). We briefly describe these classical solutions here in order to specify the color} \\
  \text{structures that enter into the subsequent treatment of the dual theory with quark sources} \\
  \text{which is not restricted to the classical approximation. We choose a gauge where the dual} \\
  \text{potential is proportional to the hypercharge matrix } Y = \frac{\lambda_3}{\sqrt{3}}: \\

  m(3.23) \quad C_\mu = C_\mu Y. \\

  \text{As a consequence the non-Abelian terms in the expression (3.21) for the dual field tensor} \\
  \text{G}_{\mu\nu} \text{ vanish.} \\

  \text{We choose Higgs Fields } B_i \text{ having the following color structure:}

  \begin{align*}
  B_1 &= B_1(x) \lambda_7 + B_1(x)(-\lambda_6) \\
  B_2 &= B_2(x)(-\lambda_5) + B_2(x) \lambda_4 \\
  m(3.24) \quad B_3 &= B_3(x) \lambda_2 + B_3(x)(-\lambda_1). 
  \end{align*}
\]
With this ansatz the Higgs potential $W$ turns out to be

$$W = \frac{2}{3} \lambda \left\{ 11 \left( |\phi_1|^2 - B_0^2 \right)^2 + (|\phi_2|^2 - B_0^2)^2 + (|\phi_3|^2 - B_0^2)^2 \right] + 7(|\phi_1|^2 + |\phi_2|^2 + |\phi_3|^2 - 3B_0^2)^2 \right\},$$

where

$$m(3.26) \quad \phi_i(x) = B_i(x) - i\tilde{B}_i(x).$$

Using (3.23) and (3.24) we also find

$$m(3.27) \quad 2 \text{tr} \sum_i (D_\mu B_i)^2 = 4(|\partial_\mu - igC_\mu|\phi_1| + 4(|\partial_\mu - igC_\mu|\phi_2| + 4|\partial_\mu \phi_3|^2.$$

Since $\phi_1$ and $\phi_2$ couple to $C_\mu$ in the same way and $\phi_3$ does not couple to $C_\mu$ at all, we can choose $\phi_1 = \phi_2 = \phi = B - i\tilde{B}$, and $\phi_3 = B_3$, so that

$$m(3.28) \quad 2 \text{tr} \sum_i (D_\mu B_i)^2 = 8(|\partial_\mu - igC_\mu|\phi|^2 + 4|\partial_\mu B_3|^2.$$

At large distances from the center of the flux tube, using cylindrical coordinates $\rho, \theta, z$ we have the boundary conditions:

$$m(3.29) \quad \tilde{C} \to -\frac{\epsilon \theta}{g\rho}, \quad \phi \to B_0 e^{i\theta}, \quad B_3 \to B_0, \text{ as } \rho \to \infty.$$ 

The non-vanishing of $B_0$ produces a color monopole current confining the electric color flux. The line integral of the dual potential around a large loop surrounding the $z$ axis measures the electric color flux, just as the corresponding line integral of the ordinary vector potential measures the magnetic flux in a superconducting vortex. Since the dual potential is along a single direction in color space path ordering is unnecessary and the boundary condition (3.29) for $\tilde{C}$ gives

$$m(3.30) \quad e^{-ig \int_{\text{loop}} \tilde{C} \cdot d\ell} = e^{2\pi i Y} = e^{2\pi i (\frac{1}{3})},$$

which manifests the unit of $Z_3$ flux in the tube. (A continuous deformation in $SU(3)$ of our particular solution into a non-Abelian configuration will leave unchanged the path ordered
integral \( P \exp(-i g \int \tilde{C} \cdot d\tilde{F}) = e^{2\pi i \frac{1}{3}} \). The energy per unit length in this flux tube is the string tension \( \sigma \). The quantity \( g^2/\lambda \) plays the role of a Landau–Ginzburg parameter. Its value can be obtained by relating the difference between the energy density at a large distance from the flux tube and the energy density at its center to the gluon condensate. This procedure gives \( g^2/\lambda = 5 \) (which is near the border between type I and type II superconductors). We get from the numerical integration of the static field equations\(^{[17]} \)

\[
\sigma \approx 1.1(24 B_0^2). \tag{3.31}
\]

We are left with two free parameters in \( \mathcal{L}_{\text{eff}} \), which we take to be \( \alpha_s = \frac{\varepsilon^2}{4\pi} = \frac{g^2}{g^2} \) and the string tension \( \sigma \).

To couple \( C_\mu \) to a \( q \bar{q} \) pair separated by a finite distance we must represent quark sources by a Dirac string tensor \( G^S_{\mu\nu} \). We choose the dual potential to have the same color structure (3.23) as the flux tube solution. Then \( G^S_{\mu\nu} \) must also be proportional to the hypercharge matrix

\[
G^S_{\mu\nu} = Y G^S_{\mu\nu}, \tag{3.32}
\]

where \( G^S_{\mu\nu} \) is given by eq. (3.10), so that one unit of \( Z_3 \) flux flows along the Dirac string connecting the quark and anti–quark. We then couple quarks by replacing \( G_{\mu\nu} \) in \( \mathcal{L}_{\text{eff}} \) (3.19) by

\[
\mathcal{L}_{\text{eff}}(G^S_{\mu\nu}) = \frac{4}{3} \left( \delta_\mu C_\nu - \delta_\nu C_\mu + G^S_{\mu\nu} \right)^2 + 8 \left( \delta_\mu - ig C_\mu \phi \right)^2 + \frac{4(\partial_\mu B_0)^2}{2} - W, \tag{3.35}
\]

Inserting (3.33) into (3.19) and using eq. (3.28) then yields the Lagrangian \( \mathcal{L}_{\text{eff}}(G^S_{\mu\nu}) \) coupling dual potentials to classical quark sources moving along trajectories \( \tilde{z}_1(t) \) and \( \tilde{z}_2(t) \):
where $W$ is given by (3.25) with $\phi_1 = \phi_2 = \phi, \phi_3 = B_3$.

It is useful, as in (3.9), to decompose $G_{\mu\nu}$ into its color electric components $\bar{D}$ and color magnetic components $\bar{H}$. Similarly we decompose $G_{\mu\nu}^S$ into its polarization components $\bar{D}_S$ and its magnetization components $\bar{H}_S$:

$$m(3.36) \qquad D^k_S = \frac{1}{2} \epsilon_{kmn} G^{Smn}, \quad H^k_S = G^S_{0k}.$$ 

Then eq. (3.34) becomes

$$m(3.37) \quad \bar{D} = -\bar{\nabla} \times \bar{C} + \bar{D}_S, \quad \bar{H} = -\bar{\nabla} C_0 - \frac{\partial \bar{C}}{\partial t} + \bar{H}_S.$$ 

The Lagrangian density $\mathcal{L}_{eff}(G_{\mu\nu}^S)$ (3.35) can then be written as the sum of an “electric” part $\mathcal{L}_0$ and a “magnetic” part $\mathcal{L}_2$, i.e.,

$$m(3.38) \quad \mathcal{L}_{eff}(G_{\mu\nu}^S) = \mathcal{L}_0 + \mathcal{L}_2,$$

where

$$m(3.39) \quad \mathcal{L}_0 = -\left\{ \frac{2}{3} \bar{D}^2 + 4|\bar{\nabla} + ig\bar{C}|^2 \phi|^2 + 2(\bar{\nabla} B_3)^2 + W \right\},$$

and

$$m(3.40) \quad \mathcal{L}_2 = \frac{2}{3} \bar{H}^2 + 4|\partial_0 - igC_0|^2 \phi|^2 + 2(\partial_0 B_3)^2,$$

and all terms involving time derivatives appear only in $\mathcal{L}_2$.

We denote by $W_{eff}(\Gamma)$ the Wilson loop of the dual theory, i.e.,

$$m(3.41) \quad W_{eff}(\Gamma) = \frac{\int D\bar{C}_\mu D\phi DB_3 e^{i \int d^4x [\mathcal{L}_{eff}(G_{\mu\nu}^S) + \mathcal{L}_{GP}]} \int D\bar{C}_\mu D\phi DB_3 e^{i \int d^4x [\mathcal{L}_{eff}(G_{\mu\nu}^S = 0) + \mathcal{L}_{GP}]} \right.}{\int D\bar{C}_\mu D\phi DB_3 e^{i \int d^4x [\mathcal{L}_{eff}(G_{\mu\nu}^S = 0) + \mathcal{L}_{GP}]} \right.}.$$ 

The functional integral $W_{eff}(\Gamma)$ eq. (3.41) determines in the dual theory the same physical quantity as $W(\Gamma)$ in Yang–Mills theory, namely the action for a quark-antiquark pair moving along classical trajectories. The coupling in $\mathcal{L}_{eff}(G_{\mu\nu}^S)$ of dual potentials to Dirac strings plays the role in the expression (3.41) for $W_{eff}(\Gamma)$ of the explicit Wilson loop integral $e^{-ie \int \alpha d\mu A_\mu(x)}$ in the expression (2.2) for $W(\Gamma)$.$^4$

$^4$ We emphasize the distinction between $W_{eff}(\Gamma)$ and the Wilson loop of the dual theory defined as an average of $e^{ig \int \bar{C} d\tau}$. This dual Wilson loop would describe the interaction of a monopole antimonopole pair. For large loops the dual Wilson loop satisfies a perimeter law in accordance with 't Hooft's observation.
The assumption that the dual theory describes the long distance $q\bar{q}$ interaction in Yang-Mills theory then takes the form:

\begin{equation}
W(\Gamma) = W_{\text{eff}}(\Gamma), \text{ for large loops } \Gamma.
\end{equation}

Large loops means that the size $R$ of the loop is large compared to the inverse mass of the Higgs particle (monopole field) $\phi$. Furthermore since the dual theory is weakly coupled at large distances we can evaluate $W_{\text{eff}}(\Gamma)$ via a semi classical expansion to which the classical configuration of dual potentials and monopoles gives the leading contribution. This then allows us to picture heavy quarks (or constituent quarks) as sources of a long distance classical field of dual gluons determining the heavy quark potential. Thus, in a certain sense the dual gluon fields $G_{\mu\nu}$ mediate the heavy quark interaction just as the electromagnetic field mediates the electron positron interaction.

Using the duality hypothesis, we replace $W(\Gamma)$ by $W_{\text{eff}}(\Gamma)$ in eqs. (2.4)-(2.6) to obtain expressions for $V_{0}(R)$ and $V_{VD}$ in the dual theory as the zero order and quadratic terms in the expansion of $i \log W_{\text{eff}}(\Gamma)$ for small velocities $\dot{z}_1$ and $\dot{z}_2$, i.e., the interaction Lagrangian $L_I$, calculated in the dual theory, is obtained from the equation

\begin{equation}
i \log W_{\text{eff}}(\Gamma) = - \int_{t_i}^{t_f} dt L_I(z_1, z_2, \dot{z}_1, \dot{z}_2).
\end{equation}

**Remark**

There has been a recent revival of interest in the role of electric magnetic duality due to the work of Seiberg,\cite{Seiberg} Seiberg and Witten,\cite{SeibergWitten} and others on super symmetric non-Abelian gauge theories. Seiberg\cite{Seiberg} considered $SU(N_c)$ gauge theory with $N_f$ flavors of massless quarks. Although he did not exhibit an explicit duality transformation he inferred the complete structure of the magnetic gauge group and hence the associated massless particle content of the dual Lagrangian. For a certain range of $N_f$ the dual theory is weakly coupled at large distances and hence the low energy spectrum of the theory consists just of the massless particles of the dual Lagrangian. Since this dual "magnetic" Lagrangian describes the same low energy physics as the original Lagrangian, the particle spectrum, mirroring the magnetic
gauge group, must appear as composites of the original “electric” gauge degrees of freedom. For \( N_f = N_c + 1 \) the dual gauge group is completely broken, the associated dual gauge bosons become massive and the quarks of the original theory are confined.

There are obvious differences between Seiberg’s example, where the number of massless fermions plays an essential role, and the example of Yang–Mills theory where neither the original theory nor the proposed dual Lagrangian \( \mathcal{L}_{eff} \) contains fermions. Here confinement manifests itself via the development of a linear potential between heavy quark sources, whereas in the supersymmetric models confinement manifests itself via the realization of the hadron spectrum as composites of the original quark variables. In the supersymmetric model these hadrons are massless and as usual the production of these particles prevents the development of a linear potential. However, all the gauge bosons of the dual theory are massive and the coupling of the pure gauge sector to quark sources would produce a long distance linear potential between these sources. The common feature of Seiberg’s supersymmetric model, where duality is “inferred”, and Yang–Mills theory, where duality is assumed, is that in both cases the dual gluons receive mass via a Higgs mechanism which is the essential element of the dual superconductor mechanism.

4 The Potential \( V_{q\bar{q}} \) in the Dual Theory

We now express the spin dependent heavy quark potential \( V_{SD} \) (2.8) in terms of quantities of the dual theory. As a first step we find relations of matrix elements of the dual field tensor \( G_{\mu\nu} \) to variations of \( W_{eff}(\Gamma) \) which are analogous to eq. (2.20) relating \( \langle F_{\mu\nu} \rangle \) to variations in \( W(\Gamma) \). Consider the variation in \( W_{eff}(\Gamma) \) produced by the change

\[
G^S_{\mu\nu}(x) \rightarrow G^S_{\mu\nu}(x) + \delta G^S_{\mu\nu}(x).
\]

(4.1)

From eq. (3.41) we find that the corresponding variation \( \delta W_{eff}(\Gamma) \) is given by

\[
\delta i \log W_{eff}(\Gamma) = \frac{4}{3} \int dx \frac{\delta G^S_{\mu\nu}(x)}{2} \langle G^{\mu\nu}(x) \rangle_{eff},
\]

(4.2)
where

$$m(4.3) \quad \langle f(C_\mu, \phi, B_3) \rangle_{\text{eff}} \equiv \frac{\int DC_\mu D\phi DB_3 e^{i \int dx \left( \mathcal{L}_{\text{eff}}(G^{\mu \nu}_{\text{eff}}) + \mathcal{L}_{\text{Dirac}} \right) f(C_\mu, \phi, B_3)} \int DC_\mu D\phi DB_3 e^{i \int dx \left( \mathcal{L}_{\text{eff}}(G^{\mu \nu}_{\text{eff}}) + \mathcal{L}_{\text{Dirac}} \right)} \right).$$

Using (3.10) to express the variation of $G^{\mu \nu}_{\text{eff}}$ in terms of the variation of the world sheet $y^\mu(\sigma, \tau)$, we obtain

$$m(4.4) \quad \int dx \frac{\delta G^{\mu \nu}_{\text{eff}}(x)}{2} \langle \delta G^{\mu \nu}(x) \rangle_{\text{eff}} = -\frac{e}{2} \varepsilon_{\mu \nu \lambda} \int_{t_1}^{t_f} dt \left[ \delta z_1^\lambda \frac{\partial z_1^\lambda}{\partial \sigma} \langle \delta G^{\mu \nu}(z_1) \rangle_{\text{eff}} - \delta z_2^\lambda \frac{\partial z_2^\lambda}{\partial \sigma} \langle \delta G^{\mu \nu}(z_2) \rangle_{\text{eff}} \right].$$

The right hand-side of eq. (4.4) arises from varying the boundary of the Dirac sheet. The variation of the interior of the sheet produces a contribution proportional to the monopole current $j_{\nu}^{\text{MON}}$:

$$m(4.5) \quad j_{\nu}^{\text{MON}}(x) \equiv \partial^\nu G_{\mu \nu}(x).$$

(See eq. A.52 of Reference 1 for details). This gives no additional contribution to eq. (4.4) since the monopole current must vanish on the Dirac sheet, so that no monopole can pass through the Dirac string connecting the charged particles. This latter assertion is just the dual of Dirac’s condition for the consistency of a theory containing both electric charges and monopoles[14].

Defining $dz^\lambda \equiv d\tau \frac{\partial z^\lambda}{\partial \tau}$, we can then write eq. (4.4) as

$$m(4.6) \quad \int dx \frac{\delta G^{\mu \nu}_{\text{eff}}(x)}{2} \langle \delta G^{\mu \nu}(x) \rangle_{\text{eff}} = -e \int (\delta z_1^\lambda d z_1^\lambda \langle \hat{G}_{\lambda \sigma}(z_1) \rangle_{\text{eff}} - \delta z_2^\lambda d z_2^\lambda \langle \hat{G}_{\lambda \sigma}(z_2) \rangle_{\text{eff}}),$$

where

$$m(4.7) \quad \hat{G}_{\mu \nu}(x) \equiv \frac{1}{2} \varepsilon_{\mu \nu \lambda} G^{\lambda \sigma}(x).$$

Choosing a variation which vanishes on the curve $\Gamma_2$, we obtain

$$m(4.8) \quad \delta i \log W_{\text{eff}}(\Gamma) = -\frac{4}{3} e \int \frac{\delta S^{\mu \nu}(z_1)}{2} \langle \hat{G}_{\mu \nu}(z_1) \rangle_{\text{eff}},$$

18
where $\delta S^{\mu\nu}(z_1)$ is given by eq. (2.19). Eqs. (4.2) and (4.8) can be written as

\[
\frac{\delta \log W_{eff}(\Gamma)}{\delta S^{\mu\nu}(z_1)} = -\frac{4}{3} e \langle \langle \hat{G}_{\mu\nu}(z_1) \rangle \rangle_{eff} = -\frac{e}{2} \varepsilon_{\mu\nu\lambda\sigma} \frac{\delta \log W_{eff}(\Gamma)}{\delta G^S_{\lambda\sigma}(z_1)},
\]

which is the dual theory analogue of eq. (2.20). The duality assumption (3.42) then gives a corresponding relation between matrix elements:

\[
\langle \langle F_{\mu\nu}(z_1) \rangle \rangle = \frac{4}{3} \langle \langle \hat{G}_{\mu\nu}(z_1) \rangle \rangle_{eff}.
\]

Eq. (4.10) gives a correspondence between local quantities in Yang–Mills theory and in the dual theory. The utility of electric-magnetic duality is that for large loops semi-classical configurations dominate the right hand side of eq. (4.10) in contrast to the rapidly fluctuating configurations of Yang–Mills potential which contribute to the left hand side. Eq. (4.10) breaks up into its electric and magnetic components:

\[
-\langle \langle F_{mn} \rangle \rangle = \frac{4}{3} \varepsilon_{mn\ell} \langle \langle H^\ell \rangle \rangle_{eff},
\]

\[
\langle \langle F_{0\ell} \rangle \rangle = \frac{4}{3} \langle \langle D_\ell \rangle \rangle_{eff},
\]

or equivalently,

\[
\langle \langle \hat{F}_{0\ell} \rangle \rangle = \frac{4}{3} \langle \langle H_\ell \rangle \rangle_{eff},
\]

\[
\langle \langle \hat{F}_{mn} \rangle \rangle = \frac{4}{3} \varepsilon_{mnk} \langle \langle D_k \rangle \rangle_{eff}.
\]

Using eqs. (4.13) and (4.14) in eq. (2.12) gives the following expression for $V^{MAG}_{LS}$ in the dual theory:

\[
V^{MAG}_{LS} = -\sum_{j=1}^{2} \frac{4}{3} m_j \varepsilon_j \cdot \langle \langle \bar{H}(z_j) \rangle \rangle_{eff} - \bar{v}_j \times \langle \langle \bar{D}(z_j) \rangle \rangle_{eff},
\]

where $e_1 = e$ and $e_2 = -e$. Note that $\langle \langle \bar{H} \rangle \rangle_{eff} - \bar{v}_j \times \langle \langle \bar{D} \rangle \rangle_{eff}$ is the magnetic field at the $j$th quark in the comoving Lorentz frame, $V^{MAG}_{LS}$ the magnetic interaction of this field with a quark having a $g$ factor 2. The fact that heavy quarks interact with a Dirac magnetic
moment is a consequence of the $\frac{1}{m}$ expansion [2] for the $q\bar{q}$ Green’s function upon which this analysis is based.

To evaluate $V_{Thomas}$ (2.13) we note from (4.12) that

$$e \int \frac{d\omega}{2m_1^2} \int \frac{d^4p_1}{(2\pi)^4} \langle F_{\mu
u}(k_1) \rangle$$

m(4.16)

$$= \frac{4}{3} \frac{e}{2m_1^2} \int dt \hat{S}_1 \cdot \hat{p}_1 \times \langle \hat{D}(z_1) \rangle_{\text{eff}},$$

and obtain

m(4.17)

$$V_{Thomas} = -\frac{1}{2} \sum_{j=1}^{2} \frac{4}{3} \frac{e_j}{m_j} S_j \cdot (\vec{v}_j \times \langle \hat{D}(z_j) \rangle_{\text{eff}}).$$

The expression (4.17) is the contribution to the potential due to the precession of the axis of the comoving frame. In appendix A it is shown that (4.17) can be written in the usual form

m(4.18)

$$V_{Thomas} = \frac{1}{2m_1} \frac{1}{R} \frac{\partial V_0}{\partial R} \hat{S}_1 \cdot \vec{v}_1 \times \hat{R} - \frac{1}{2m_2} \frac{\partial V_0}{\partial R} \hat{S}_2 \cdot \vec{v}_2 \times \hat{R}.$$  

Eq. (4.18) is essentially a kinematic relation and is independent of the dynamics of Yang–Mills theory. On the other hand $V_{LS}^{MAG}$, eq. (4.15), depends upon the dynamics and cannot be expressed solely in terms of the central potential.

To express $V_{SS}$ (2.17) in terms of quantities involving the dual theory we need the following:

$$ie^2 \{ \langle \hat{F}_{\lambda 0}(z_j) \hat{F}_{\lambda 0}(z'_j) \rangle - \langle \hat{F}_{\lambda 0}(z_j) \hat{F}_{\lambda 0}(z'_j) \rangle \}$$

m(4.19)

$$= \frac{4}{3} e^2 \frac{\delta \langle H_k(z_j) \rangle_{\text{eff}}}{\delta H_{\lambda 0}(z'_j)}.$$ 

To obtain (4.19) we use eqs. (2.21) and (4.13) and the equation

m(4.20)

$$\frac{\delta \langle H_k(z_j) \rangle_{\text{eff}}}{\delta G_{\lambda 0}^{\lambda 0}(z'_j)} = -\frac{\epsilon_{mn}}{2} \frac{\delta \langle H_k(z_j) \rangle_{\text{eff}}}{\delta S_{\lambda 0}^{mn}(z'_j)}.$$  

(Compare eq. (4.9)). Using eq. (4.19) in (2.17), we obtain

m(4.21)

$$\int dt V_{SS} = -\frac{1}{2} \sum_{j,j'=1}^{2} \frac{e^2}{m_j m_{j'}} T_s \int_{\Gamma_j} dt \int_{\Gamma_{j'}} dt' S_j^l S_{j'}^l \left( \frac{4}{3} \frac{\delta \langle H_k(z_j) \rangle_{\text{eff}}}{\delta H_{\lambda 0}(z'_j)} \right).$$
The factor multiplying $S^k_j S^k_j$ is symmetric in $k$ and $\ell$ and hence the terms in eq. (4.21) where $j = j'$ involve the combination
\[ \frac{S^k_j S^k_j + S^k_j S^\ell_j}{2} = \frac{1}{4} \delta_{kt}. \]

Eq. (4.21) then becomes
\[ \int dt V_{SS} = -\frac{4}{3} \sum_{j=1}^{2} \frac{e^2}{8m_j^2} \int_{\Gamma_j} dt \int_{\Gamma_j} dt' \frac{\delta \langle \{ H_k(z_j) \} \rangle_{\text{eff}}}{\delta H_{sk}(z_j')} \]

The first term in eq. (4.22) is a spin independent velocity independent contribution to the potential proportional to inverse square of the quark masses while the second term in eq. (4.22) yields a spin-spin interaction of the expected structure.

Finally, let us come to $V_{\text{Darwin}}$ (2.15) and note that
\[ \langle D^\nu F_{\nu\mu}(z_j) \rangle = \partial^\nu \langle F_{\nu\mu}(z_j) \rangle. \]

The derivative of the Wilson loop occurring in the definition (2.10) of $\langle F_{\nu\mu}(x) \rangle$ yields the Yang–Mills potential $A_\nu$ appearing in $D^\nu F_{\nu\mu}$. Using (4.10) we obtain 5
\[ \int V_{\text{Darwin}} dt = -\frac{4}{3} \sum_j \frac{e}{8m_j^2} \int_{\Gamma_j} dx^\mu \partial^\nu \langle \hat{G}_{\nu\mu}(x) \rangle_{\text{eff}}. \]

For an alternative expression for $V_{\text{Darwin}}$ based on (eq. A.7) of Ref. [4] see eq. B.3 of Appendix B.

### 5 The Classical Approximation for $V_0(R)$ and $V_{VD}$

In the classical approximation eq. (3.41) becomes
\[ i \log W_{\text{eff}} = -\int dx L_{\text{eff}}(G_{\mu\nu}^S), \]

---

5 Notice that $\langle \{ F_{\mu\nu}(z) \} \rangle$ depends not only on the point $z$ but on the entire Wilson loop. So in order for eq. (4.23) to make sense one has to use the appropriate definition of derivative. Given a functional $\Phi_{[\gamma_{ab}]}$ of the curve $\gamma_{ab}$ with ends $a$ and $b$, under general regularity condition the variation of $\Phi$ consequent to an infinitesimal modification of the curve $\gamma \rightarrow \gamma + \delta \gamma$ can be expressed as the sum of various terms proportional respectively to $\delta a, \delta b$, and to the elements $\delta S_{\rho\sigma}(z)$ of the surface swept by the curve. Then the derivatives $\partial/\partial a^\rho, \partial/\partial b^\rho$ and $\delta/\delta S_{\rho\sigma}(x)$ are defined by the equation $\delta \Phi = \partial \Phi/\partial a^\rho \delta a^\rho + \partial \Phi/\partial b^\rho \delta b^\rho + \int_{\gamma} \delta S_{\rho\sigma}(x) \delta \Phi/\delta S_{\rho\sigma}(x)$. In our case this would amount to put naively $\partial/\partial z^\rho P f(\int_{z}^{b} dx^\mu A_\mu(x)) = -P f'(\int_{z}^{b} dx^\mu A_\mu(x)) A_\rho(x)$ and $\partial/\partial z^\rho \int_{a}^{z} dx^\mu A_\mu(x) = A_\rho(z) P f'(\int_{a}^{z} dx^\mu A_\mu(x))$. 

where $\mathcal{L}_{eff}(G^S_{\mu\nu})$ (3.35) is evaluated at the solution of the classical equations of motion:

\begin{equation}
\partial^\alpha (\partial_\alpha C_\beta - \partial_\beta C_\alpha) = -\partial^\alpha G^S_{\alpha\beta} + j^{MON}_\beta \tag{5.2} \end{equation}

\begin{equation}
(\partial_\mu - igC_\mu)^2\phi = \frac{1}{4} \frac{\delta W}{\phi^*} \tag{5.3} \end{equation}

and

\begin{equation}
\partial^2 B_3 = -\frac{1}{4} \frac{\delta W}{\delta B_3} \tag{5.4} \end{equation}

where the monopole current $j^{MON}_\mu$ is

\begin{equation}
j^{MON}_\mu = -3ig[\phi^*(\partial_\mu - igC_\mu)\phi - \phi(\partial_\mu + igC_\mu)\phi^*]. \tag{5.5} \end{equation}

As a result of the classical approximation all quantities in brackets are replaced by their classical values

\begin{equation}
\langle[G_{\mu\nu}(x)]\rangle_{eff} = G_{\mu\nu}(x). \tag{5.6} \end{equation}

The electric and magnetic components of eq. (5.6) are

\begin{equation}
\langle\bar{D}(x)\rangle_{eff} = \bar{D}(\bar{x}), \quad \langle\bar{H}(x)\rangle_{eff} = \bar{H}(\bar{x}), \tag{5.7} \end{equation}

where $\bar{D}$ and $\bar{H}$ are the color electric and magnetic fields respectively given in terms of the dual potentials by eq. (3.37).

We choose the Dirac string to be a straight line $L$ connecting the quarks. As $\bar{x}$ approaches the string, $\phi(x) \to 0$, $C_\mu(x) \to C^D_\mu(x)$, satisfying eq. (3.17). As $\bar{x} \to \infty$, $\phi(x) \to B_0$, $C_\mu(x) \to 0$, in contrast with the large distance boundary condition for the infinite flux tube. We can then choose $\phi(x)$ to be real so that

\begin{equation}
\phi(x) = B(x), \quad j^{MON}_\mu(x) = -6g^2C_\mu B^2. \tag{5.8} \end{equation}

Consider first the case of static quarks, $\vec{v}_1 = \vec{v}_2 = 0$. Then the scalar potential $C_0$ and the color magnetic field $\bar{H}$ vanish, and $\mathcal{L}_{eff}$ reduces to $\mathcal{L}_0$ eq. (3.39) which yields the static potential:

\begin{equation}
V_0(R) = -\int d\bar{x} \mathcal{L}_0, \tag{5.9} \end{equation}
where $L_0$ is evaluated at the static solution of eqs. (5.2) - (5.4), which have the following form in this case:

\begin{equation}
-\vec{\nabla} \times (\vec{\nabla} \times \vec{C}) - 6g^2 B^2 \vec{C} = -\vec{\nabla} \times \vec{D}_S,
\end{equation}

\begin{equation}
(-\nabla^2 + g^2 \vec{C}^2) B = -\frac{2\lambda}{3} B (25B^2 + 7B_s^2 - 32B_0^2),
\end{equation}

and

\begin{equation}
-\nabla^2 B_3 = -\frac{4\lambda}{3} B_3 (7B^2 + 9B_s^2 - 16B_0^2),
\end{equation}

where we have used the explicit form, eq. (3.25), of W.

To solve eq. (5.10) it is convenient to write

\begin{equation}
\vec{C} = \vec{C}^D + \vec{c},
\end{equation}

where $\vec{C}^D$ is the Dirac potential satisfying the static form of eq. (3.17) namely:

\begin{equation}
-\vec{\nabla} \times (\vec{\nabla} \times \vec{C}^D) = -\vec{\nabla} \times \vec{D}_S,
\end{equation}

with $\vec{D}_S$ given by eq. (3.36). In cylindrical coordinates with the $z$ axis along the line joining the two quarks at $z = \pm R/2$, eq. (3.10) gives

\begin{equation}
\vec{D}_S = e \hat{\varepsilon}_z \{ \theta(z - R/2) - \theta(z + R/2) \} \delta(x) \delta(y),
\end{equation}

which describes the polarization vector for a line of dipoles. The solution of eq. (5.14) is

\begin{equation}
\vec{C}^D = \hat{\varepsilon}_\phi C^D,
\end{equation}

where

\begin{equation}
C^D = \frac{e}{4\pi \rho} \left\{ \frac{z - R/2}{\sqrt{\rho^2 + (z - R/2)^2}} - \frac{(z + R/2)}{\sqrt{\rho^2 + (z + R/2)^2}} \right\}.
\end{equation}

Then

\begin{equation}
\vec{c} = \hat{\varepsilon}_\phi \vec{c},
\end{equation}
and eq. (5.10) becomes the following equation for $c$:

\[
(\nabla^2 - 6g^2B^2)c = 6g^2B^2C^D,
\]

m(5.19)

where

\[
\nabla^2 f(\rho, z) \equiv \frac{\partial}{\partial \rho} \left( \frac{1}{\rho} \frac{\partial f}{\partial \rho} (\rho f) \right) + \frac{\partial^2 f}{\partial z^2}.
\]

m(5.20)

Eqs. (5.11), (5.12) and (5.19) are three nonlinear equations for the static configuration $c, B,$ and $B_3$ with boundary conditions: $c \rightarrow -C^D, B \rightarrow B_0, B_3 \rightarrow B_0$ at large distances; $c \rightarrow 0, B \rightarrow 0$ for $\vec{z}$ on $L$. These equations have been solved in ref.\textsuperscript{[19]} with the following results:

The monopole current in eq. (5.10) screens the color electric field produced by the quark sources so that as the quark anti-quark separation increases the lines of $\vec{D}$ are compressed from their Coulomb like behavior at small $R$ to form a flux tube, and thus $V_0(R) \rightarrow \sigma R$ at large $R$. Both this small $R$ and this large $R$ behavior of the potential have their common origin in the evolving distribution of the flux of $\vec{D}$ whose divergence is fixed by the color electric charge of the quarks ($\vec{\nabla} \cdot \vec{D} = \vec{\nabla} \cdot \vec{D}_S$) and whose curl is determined by the monopole current. Thus, the dual theory already in the classical approximation gives a potential which evolves smoothly from the large $R$ confinement region to the short distance perturbative domain. This shows how the dual theory realizes the Mandelstam 't Hooft mechanism. It does not describe QCD at shorter distances where radiative corrections giving rise to asymptotic freedom and a running coupling constant are important.

To calculate the terms in $i \log W_{eff}$ which are quadratic in the quark velocities we solve the field equations for moving quarks. To first order in the velocities the static field distributions follow the quark motion adiabatically. The time dependence of $\vec{C}, B$ and $B_3$ then results from the explicit time dependence of $R$. Furthermore, since $\int d\vec{x} \mathcal{L}_0$ generates the static field equations, it is stationary about the solution to these equations and remains unchanged to second order in the velocities. The velocity dependence in the potential then comes from the “magnetic” contribution $\mathcal{L}_2$ which depends quadratically upon $\partial_0 \vec{C}, \partial_0 B_3,$ and $C_0$, all of
which are first order in the velocities. The scalar potential $C_0$ satisfies the equation, obtained from the time component of eq. (5.2),

$$\nabla^2 C_0 - 6g^2 B^2 C_0 = \vec{\nabla} \cdot \vec{H}_S,$$

valid to first order in the velocities. With the Higgs field $B(\vec{x})$ already determined by the static equations, eq. (5.21) is a linear equation for the scalar potential, giving $C_0$ to first order in the velocity. The velocity dependent potential $V_{VD}$ is then given by

$$V_{VD} = -\int d\vec{x} \mathcal{L}_2,$$

representing the magnetic color energy due to the fields following the moving quarks.

For small $R$ the potential $V_{VD}$ approaches the velocity dependent part of the Darwin potential (3.7) (multiplied by the color factor $4/3$) because for small $R$ the color magnetic field $\vec{H}(\vec{x})$ becomes the ordinary Biot–Savart magnetic field. As $R$ increases the color magnetic field lines are compressed so that for large separation $V_{VD}$ becomes linear in $R$. As an example consider the case in which two equal mass quarks move in a circular orbit of frequency $\omega$. Then $\vec{v}_1 = -\vec{v}_2 = \frac{\vec{x} \times \vec{R}}{2}$, and $V_{VD}$ reduces to

$$V_{VD} = -\frac{1}{2} I(R) \omega^2,$$

which defines the momentum of inertia $I(R)$ of the rotating flux tube distribution. Eq. (5.22) evaluated for this configuration of moving quarks then determines $I(R)$. For Large $R$ we find\cite{1}

$$\lim_{R \to \infty} I(R) = \frac{1}{2} (AR)R^2,$$

where

$$A \simeq .21\sigma,$$

determined numerically from eq. (5.22). By comparison we note that the moment of inertia $I'$ of an infinitely thin flux tube of length $R$ is

$$I'(R) = \frac{1}{2} (A'R)R^2,$$
A/0 \neq n_{1b}/6:

\text{m}/n_{28}/5./2/n_{29}

The comparison of eq. (5.27) describing an infinitely thin flux tube with eq. (5.25) gives a quantitative estimate of the increase of the moment of inertia of the flux tube due to its finite thickness.

We now compare these results for \( V_0 + V_{VD} = -L_I \) of the dual theory with the "modified area law" model\(^9\), eq. (2.22). In the dual theory \( i \log W(\Gamma) \) is replaced by \( i \log W_{eff}(\Gamma) \), given in the classical approximation by eq. (5.1). This gives in the limit of short distances the perturbative expression eq. (3.7) so that the short distance limit of the dual theory is the short range component \( i \log W^{SR}(\Gamma) \). The long distance limit of \( i \log W_{eff}(\Gamma) \) is fixed by the values of \( \sigma \) and \( A \). Replacing \( A \) by \( A' \) in this limit yields \( i \log W^{LR}(\Gamma) \). This shows that \( i \log W^{LR}(\Gamma) \) describes a zero width flux tube. Aside from this difference we see that the "two components" of eq. (2.22) arise as two limits of a single classical solution describing the evolution of the potential produced by compression of the field lines with increasing \( R \).

As the simplest example of the implications of \( V_{VD} \), we add relativistic kinetic energy terms to \( -(V_0 + V_{VD}) \) to obtain a classical Lagrangian, and calculate classically the energy and angular momentum of \( q\bar{q} \) circular orbits, which are those which have the largest angular momentum \( J \) for a given energy. We find\(^{20} \) a Regge trajectory \( J \) as a function of \( E^2 \) which for large \( E^2 \) becomes linear with slope \( \alpha' = J/E^2 = 1/8\sigma(1-A/\sigma) \). Then (5.25) gives \( \alpha' \approx 1/6.3\sigma \), which is close to the string model relation \( \alpha' = \frac{1}{2\sigma} \). This comparison shows how at the classical level a string model emerges when the velocity dependence of the \( q\bar{q} \) potential is included. The fact that the difference between the two expressions for \( \alpha' \) is small indicates that the infinity narrow string may be a good approximation to the finite width flux tube forms between the \( q\bar{q} \) pair.

To summarize:

1) The potential \( V_0(R) \) is determined by eqs. (5.9) and (3.39) evaluated at the static solution.
2) The potential $V_{\alpha\beta}$ is given by eqs. (5.22) and (3.40) evaluated at the solution of the classical equations to first order in the velocity squared. The resultant integrals have been calculated numerically and determine four functions $V_+(R)$, $V_-(R)$, $V_L(R)$ and $V_H(R)$ which specify uniquely the terms in the potential proportional to the velocity squared. Explicit expressions for these functions are given in reference 1.

Remarks

1. In the absence of quark sources ($G^{\mu\nu}_S = 0$), $\mathcal{L}_{\text{eff}}$ describes a system of massive dual gluons and monopoles. Because of the dual Higgs mechanism there are no unwanted massless particles in the spectrum. The massive particles of the dual theory cannot be identified with the massive particles of Yang–Mills theory, since the dual theory just describes the low energy spectrum. These masses determine rather the scale $R_{FT} = \frac{1}{M}$ above which the dual theory should describe the $q\bar{q}$ interaction. Since a quark anti-quark pair moving in an orbit of radius $R$ can only radiate a particle of mass $M$ if $\frac{1}{R} > M$, in the domain $R > \frac{1}{M}$ where the dual theory describes Yang–Mills theory no dual gluons or monopoles are emitted. The glueballs of Yang–Mills theory, on the other hand, are described by closed loops of color flux, obtained by coupling the dual potentials to closed Dirac strings and finding the corresponding static solution of the field equations of the dual theory.

2. The Lagrangian density $\mathcal{L}_{\text{eff}}$ (3.35) describes the coupling of the Dirac string to Abelian configurations of dual potentials, and the functional integral (3.41) for $W_{\text{eff}}(\Gamma)$ is restricted to such configurations. The external $q\bar{q}$ pair has in effect selected out a particular sector of the dual theory relevant to the $q\bar{q}$ potential. As a consequence the resulting potential should not be very sensitive to the details of the dual gauge group.

3. The Dirac string in the classical solution was a straight line connecting the $q\bar{q}$ pair. This gave the configuration having the minimum field energy. The flux tube corresponding to a given string position is concentrated in the neighborhood of that string since the monopole

---

The Dirac string of the dual theory, in contrast to that of electrodynamics, is physical. The vanishing of the Higgs field on the string produces a vortex and an associated flux tube containing energy. This vortex can not be removed by a gauge transformation since such a transformation leaves the magnitude of the Higgs field unchanged.
current vanishes there. To evaluate the contributions to the potential arising from fluctuations of the shape and length of the flux tube, we must integrate over field configurations generated by all Dirac strings connecting the \( q \bar{q} \) pair. This amounts to doing a functional integral over all Dirac polarization tensors \( G_{\mu\nu}(x) \). Similar integrals have recently been carried out by Akhmedov, et al., in a somewhat different context. The functional integral over \( G_{\mu\nu}(x) \) is replaced by a functional integral over corresponding world sheets \( y(\sigma, \tau) \), multiplied by an appropriate Jacobian. As a result they obtain an effective string theory free from the conformal anomaly. Such techniques when applied in the context of the dual theory should lead to a corresponding effective string theory.

6 The Classical Approximation for \( V_{SD} \)

In this section we evaluate the expression for \( V_{SD} \) given in Section four using the classical solutions to the dual theory described in Section five. We consider separately the four contributions to \( V_{SD} \) (See eq. (2.8)):

(1) \( V_{Thomas} \): Eq. (4.17)-(4.18) with \( V_0(R) \) determined by eq. (5.9).

(2) \( V^{MAG}_{LS} \): Eq. (4.15) with \( \langle \langle \tilde{D} \rangle \rangle_{eff} \) and \( \langle \langle \tilde{H} \rangle \rangle_{eff} \) replaced by their classical values \( \tilde{D} \) and \( \tilde{H} \), namely

\[
V^{MAG}_{LS} = - \sum_{j=1}^{2} \frac{4}{3m_{j}} \bar{S}_j \cdot (\tilde{H}(\bar{z}_j) - \bar{v}_j \times \tilde{D}(\bar{z}_j)),
\]

with \( \tilde{H} - \bar{v}_j \times \tilde{D} \) calculated to first order in the velocity. To this order the static field configurations follow the motion of the quarks adiabatically and we find from eq. (3.37)

\[
\tilde{H}(\bar{z}_j) - \bar{v}_j \times \tilde{D}(\bar{z}_j) = - \bar{v}(C_0(\bar{x}) - \tilde{C}(\bar{x}) \cdot \bar{v}(\bar{x})) \bigg|_{\bar{z} = \bar{z}_j},
\]

where

\[
\bar{v}(\bar{x}) = \frac{\bar{v}_1 + \bar{v}_2}{2} + \bar{\omega} \times \bar{x},
\]

and

\[
\bar{\omega} = \frac{\vec{R} \times \frac{d\vec{R}}{dt}}{R^2}.
\]
In eqs. (6.2-6.4), \( \frac{\ddot{\omega} + i \dot{\omega}}{2} \) is the instantaneous velocity of the origin of the coordinates which we have chosen as the midpoint of the line \( L \) connecting the \( q\bar{q} \) pair and \( \ddot{\omega} \) is the instantaneous angular velocity of \( L \). (The motion of the \( q\bar{q} \) pair along \( L \) does not contribute to eq. (6.2)).

We can understand the result eq. (6.2), as follows: The left hand side is the color magnetic field at the position of the \( j \)th quark in the Lorentz system in which it is instantaneously at rest. The magnetic field in this comoving system is determined by the gradient of the corresponding dual scalar potential, namely \( C_0 - C \cdot \bar{v} \). Indeed (6.2) remains valid beyond the classical approximation with the replacement \( C_0 \rightarrow \langle C_0 \rangle_{\text{eff}}, \bar{C} \rightarrow \langle \bar{C} \rangle_{\text{eff}} \).

Choosing \( \bar{R} \) to lie along the \( z \) axis and using eqs. (5.21) and (5.10) for \( C_0 \) and \( \bar{C} \) we find:

\[ C_0 - \bar{C} \cdot \bar{v} = \dot{\epsilon}_\phi \cdot \frac{d\bar{R}}{dt} C_-(z, \rho), \]

where \( \rho, \phi, z \) are cylindrical coordinates, and

\[ C_-(z, \rho) = C_-(z, \rho) + c_-(z, \rho), \]

where

\[ C_d(z, \rho) = \frac{e\rho}{4\pi \bar{R}} \left\{ \frac{1}{\sqrt{\rho^2 + (z - \frac{R}{2})^2}} - \frac{1}{\sqrt{\rho^2 + (z + \frac{R}{2})^2}} \right\}, \]

and where \( c_-(z, \rho) \) satisfies the equation

\[ (\bar{\nabla}^2 - 6g^2 B^2)c_-= 6g^2 B^2 C_d. \]

The solution of the linear integral equation (6.8) for \( c_- \) determines, via eqs. (6.2) and (6.5) the non-perturbative part of the color magnetic field in the comoving Lorentz system. From eqs. (6.6)-(6.8) it follows that for any fixed value of \( z \) and \( \rho \) this field vanishes like \( \frac{1}{R} \) for large \( q\bar{q} \) separation. The vanishing of this field at large \( R \) is in accordance with the observation of Buchmuller\cite{23} that in a flux tube picture the color field in the comoving frame should be purely electric. However, for any finite value of the \( q\bar{q} \) separation there is a color magnetic field in this system, and eqs. (6.1)-(6.8) give

\[ V_{\text{MAG}}^{\text{LS}} = \frac{V'(R)}{R} \left\{ \left( \frac{\vec{S}_1 \cdot (\bar{R} \times \vec{p}_1)}{m_1^2} - \frac{\vec{S}_2 \cdot (\bar{R} \times \vec{p}_2)}{m_2^2} \right) + \left( \frac{\vec{S}_2 \cdot (\bar{R} \times \vec{p}_1)}{m_1 m_2} - \frac{\vec{S}_1 \cdot (\bar{R} \times \vec{p}_2)}{m_1 m_2} \right) \right\}, \]

\[ \text{where} \]
where

\[ V_2'(R) = \frac{4}{3} \left\{ \frac{\alpha_s}{R^2} - \frac{1}{2\rho} \frac{\partial}{\partial \rho} [\rho c_-(\rho, z)] \right\} \left. \right|_{\rho = 0} \].

The first term in (6.10) is the perturbative contribution to \( V_2'(R) \) arising from \( C_D^L \) and the second term is the non-perturbative part which behaves like \( \frac{1}{R} \) for large \( R \) and which would not be present in the simple flux tube picture of Buchmuller.

Finally adding \( V_{LS}^{MAG} \) to \( V_{Thomas} \) gives the complete expression for the spin orbit coupling \( V_{LS} \),

\[ V_{LS} = \left[ \frac{1}{R} \frac{dV_0}{dR} + 2 \frac{V_1'(R)}{R} \left( \frac{\vec{S}_1 \cdot \vec{R} \times \vec{p}_1}{2m_1^2} - \frac{\vec{S}_2 \cdot \vec{R} \times \vec{p}_2}{2m_2^2} \right) + \frac{V_2'(R)}{R} \left( \frac{\vec{S}_2 \cdot \vec{R} \times \vec{p}_1}{m_1m_2} - \frac{\vec{S}_1 \cdot \vec{R} \times \vec{p}_2}{m_1m_2} \right) \right], \]

where

\[ V_1'(R) = V_2'(R) - \frac{dV_0}{dR}. \]

Eq. (6.11) expresses the spin orbit potential in terms of the central potential and a single independent function \( V'_2(R) \) determined by the dual scalar potential \( C_0 - \vec{C} \cdot \vec{v} \) in the comoving frame. This result for \( V_{LS} \) satisfies identically the constraints of Lorentz invariance (6.12) (The Gromes Relations).

Furthermore, since \( V_2'(R) \rightarrow \frac{1}{R} \) for large \( R \), we have

\[ \lim_{R \rightarrow \infty} V_1'(R) = - \frac{dV_0}{dR} = -\sigma, \]

which is the value given by the flux tube model for all \( R \).

**3 \( V_{SS} \):** Eq. (4.22) with \( \frac{\delta \bar{H}(z)}{\delta H_S(z')} \) replaced by \( \frac{\delta \bar{H}(z)}{\delta H_S(z')}. \) Since, to first order in the velocity, \( \bar{C} \) is determined by \( \bar{D}_S \) alone (see eq. (5.10)) the \( \frac{\partial \bar{C}}{\partial \alpha} \) term in \( \bar{H} \) does not contribute to its variational derivative with respect to \( \bar{H}_S \) and eq. (3.37) gives

\[ \frac{\delta H_k(x)}{\delta H_{Sk}(x')} = \delta_{kl} \delta(t - t') - \nabla_k \frac{\delta C_0(x)}{\delta H_{Sk}(x')} \].

The quantity \( \frac{\delta C_0}{\delta H_S} \) in turn satisfies the equation obtained by taking the variational derivative of eq. (5.21) with respect to \( \bar{H}_S \), namely

\[ (\nabla^2 - 6g^2 B^2) \frac{\delta C_0(x)}{\delta H_{Sl}(x')} = \nabla_t \delta(t - t') \delta(x - x'). \]
The double integral in eq.(4.22) then becomes a single integral over \( t \) of the static quantity \( \frac{\delta H(z)}{\delta H_{\xi}(z')} \). We emphasize that this simplification obtains only in the classical approximation we are now considering.

Eqs. (6.14) and (6.15) give

\[
m(6.16) \quad \frac{\delta H_k(x)}{\delta H_{St}(x')} = \delta_{k\ell} \delta(x-x') + \nabla_k \nabla'_\ell G(x, x'),
\]

where the Green’s function \( G(x, x') \) satisfies

\[
m(6.17) \quad (-\nabla^2 + 6g^2 B^2(x)) G(x, x') = \delta(x-x').
\]

\( G(x, x') \) is the potential at \( x \) due to a point charge at \( x' \) in presence of the monopole charge density \( j_0^{MON} \) (5.8) carried by \( B(x) \). Since \( B(x) \) approaches its vacuum value \( B_0 \) as \( x \to \infty \), \( G \) vanishes exponentially at large distances, i.e.,

\[
m(6.18) \quad G(x, x') \bigg|_{x \to \infty} = \frac{e^{-m_B|\bar{x}-\bar{x}'|}}{4\pi|\bar{x}-\bar{x}'|^4},
\]

where

\[
m(6.19) \quad m_B^2 = 6g^2 B_0^2 = \frac{6\pi}{\alpha_s} B_0^2 \approx \frac{\pi}{4} \frac{\sigma}{\alpha_s},
\]

and where we used the result, \( \sigma \approx 24 B_0^2 \), obtained from the energy per unit length of the static flux tube solution. Using a value \( \alpha_s = .37 \) obtained from fitting the \( cc \) and \( bb \) spectrum\(^1\) we obtain \( m_B \approx 640 MeV \).

Separating off the Coulomb contribution to \( G \) we have

\[
m(6.20) \quad G = -\frac{1}{4\pi|\bar{x}-\bar{x}'|} + G^{NP},
\]

where \( G^{NP} \) satisfies the equation

\[
m(6.21) \quad (-\nabla^2 + 6g^2 B^2) G^{NP} = -\frac{6g^2 B^2(x)}{4\pi|\bar{x}-\bar{x}'|}.
\]

Inserting eqs. (6.16) and (6.20) into eq. (4.22) gives

\[
m(6.22) \quad V_{SS} = V_{SS}^{spin} + V_{SS}^{1/m^2},
\]

31
where

\[
m(6.23) \quad V_{SS}^{\text{spin}} = \frac{4}{3 m_1 m_2} \left\{ \left( \vec{S}_1 \cdot \vec{S}_2 \right) \delta(\vec{z}_1 - \vec{z}_2) + \left( \vec{S}_1 \cdot \vec{\nabla} \right) \left( \vec{S}_2 \cdot \vec{\nabla}' \right) G(\vec{x}, \vec{x}') \right\}_{\vec{z'} = \vec{z}_1, \vec{x'} = \vec{z}_2},
\]

\[
m(6.24) \quad V_{SS}^{1/m^2} = -\frac{4}{3} \sum_{j=1}^{2} \frac{e^2}{3m_j^2} \vec{\nabla} \cdot \vec{\nabla}' G^{NP}(\vec{x}, \vec{x}').
\]

The potential \( V_{SS}^{\text{spin}} \) is the same as previously obtained\(^{[11]} \). At small \( R \) it approaches the usual perturbative spin-spin interaction, and at long distances it is exponentially damped due to screening by the monopole charge. The spin independent contribution \( V_{SS}^{1/m^2} \) of \( V_{SS} \) depends upon \( R \) via the dependence in eq. (6.21) of \( G^{NP} \) on \( B \). It was not included in ref.\(^{[11]} \).

(4) \( V_{\text{Darwin}} \): Eq. (4.24) with \( \langle \hat{G}_{\mu\nu} \rangle_{\text{eff}} \) replaced by \( \hat{G}_{\mu\nu} \), namely

\[
m(6.25) \quad \int V_{\text{Darwin}} dt = -\frac{4}{3} \sum_{j=1}^{2} \frac{e}{3m_j^2} \int_{\Gamma_j} dx^\nu \partial^\nu \hat{G}_{\nu\mu}(x).
\]

To evaluate (6.25) we note from eqs. (3.11) and (3.34) that

\[
m(6.26) \quad \partial^\nu \hat{G}_{\nu\mu}(x) = j_\mu(x),
\]

where \( j_\mu(x) \) is the quark anti-quark current. The monopole current does not contribute to \( \partial^\nu \hat{G}_{\nu\mu} \) and \( V_{\text{Darwin}} \) becomes,

\[
m(6.27) \quad \int V_{\text{Darwin}} dt = -\frac{4}{3} \sum_{j=1}^{2} \frac{e}{3m_j^2} \int_{\Gamma_j} dx^\mu j_\mu(x) = -\frac{4}{3} \sum_{j=1}^{2} \frac{e_j}{3m_j^2} \int dt \rho(z_j).
\]

Omitting self energy terms we insert \( \rho(z_1) = -e\delta(z_1 - \vec{z}_2), \rho(z_2) = e\delta(\vec{z}_2 - z_1) \) into eq. (6.27) and obtain

\[
m(6.28) \quad V_{\text{Darwin}} = \frac{e^2}{6} \left( \frac{1}{m_1^2} + \frac{1}{m_2^2} \right) \delta(z_1 - \vec{z}_2).
\]

In Appendix B we show that the alternate form (B.3) for \( V_{\text{Darwin}} \) reduces in the classical approximation to the same expression (6.28).

There are two then spin independent terms proportional to \( \left( \frac{1}{m_1^2} + \frac{1}{m_2^2} \right) \). The first is \( V_{SS}^{1/m^2} \) (6.24). The second is \( V_{\text{Darwin}} \) (6.28).
To summarize: In reference 4 the coefficient of \( \left( \frac{1}{m_1^2} + \frac{1}{m_2^2} \right) \) in the velocity dependent potential was written as:

\[
m(6.29) \quad V_{SS}^{1/m_2^2} + V_{Darwin} \equiv \frac{1}{8} \left( \frac{1}{m_1^2} + \frac{1}{m_2^2} \right) \nabla^2 (V_0(R) + V_a(R))
\]

which defines \( V_a \). Eqs. (6.24) and (6.28) give

\[
m(6.30) \quad \nabla^2 V_a = \nabla^2 V_0^{NP}(R) - \frac{4}{3} e^2 \vec{\nabla} \cdot \vec{\nabla} G^{NP}(\vec{x}, \vec{x}') \bigg|_{\vec{x} = \vec{x}' = \vec{x}_j},
\]

where \( V_0^{NP}(R) \) is the non-perturbative part of the central potential so that \( V_a \) is determined by the non-perturbative dynamics of Yang–Mills theory. The first term in (6.30) is the color electric contribution to \( V_a \) and the second is the color magnetic contribution.

The spin dependent potential is then given by:

\[
m(6.31) \quad V_{SD} = V_{LS} + V_{SS}^{spin} + \frac{1}{8} \left( \frac{1}{m_1^2} + \frac{1}{m_2^2} \right) \nabla^2 (V_0(R) + V_a(R))
\]

with \( V_{LS} \) given by (6.10) and (6.11), \( V_{SS}^{spin} \) by (6.23) and \( V_a(R) \) by (6.30).

It should be emphasized that these results along with those of section 5 do not account for quantum fluctuations about the classical solutions. To account for these fluctuations we must return to the more general eqs. (4.15), (4.22) and (4.24) and (4.3) which determine \( V_{q\bar{q}} \) in the dual theory independent of the classical approximation.

### 7 Conclusion

We have shown how the analysis of ref.[8] of the heavy quark potential \( V_{q\bar{q}} \) in terms of Wilson loops \( W(\Gamma) \) leads to the expression for the long distance behavior of \( V_{q\bar{q}} \) in terms of an effective Wilson loop \( W_{eff}(\Gamma) \) calculated in a dual theory describing a dual superconductor. The coupling of the dual theory to heavy quarks is then uniquely specified with spin and relativistic effects accounted for unambiguously to order \( \left( \frac{1}{mass_{quark}} \right)^2 \), the highest order for which the concept of a potential makes sense.

The calculation of \( W_{eff}(\Gamma) \) in the classical approximations leads to expressions for the various terms in \( V_{q\bar{q}} \) with clear physical interpretations. These results coincide for the most
part with the expressions for $V_{q\bar{q}}$ given by a previous dual theory calculation[1] in which the $q\bar{q}$ motion was treated semi-classically. The present treatment gives an additional contribution, (6.29) to $V_{q\bar{q}}$, and the contribution of “Thomas precession” now appears automatically whereas in the semi-classical treatment it has to be put in by hand.

We can use the Wilson loop $W_{\text{eff}}(\Gamma)$ to approximate $W(\Gamma)$ for large loops, i.e., for $R > \frac{1}{M}$, where $M$ is either the mass of dual gluon $C_\mu$ or of the monopole field $B_i$ (about 500MeV). However, since the dual theory gives a heavy quark potential which approaches lowest order perturbation theory for small $R$, it should remain applicable down to distances where radiative corrections giving rise to a running coupling constant become important.

Most significant is the fact that we have obtained an expression for the $q\bar{q}$ potential in the dual theory which makes no reference to the classical approximation. Furthermore since the formulae of reference [2] are obtained starting from a relativistic treatment of the $q\bar{q}$ QCD interaction, the results provide a direct connection of the dual theory to QCD which could lead to an understanding of the constituent quark model on a more fundamental level.

As a final remark we note that the dual theory we propose is an SU(3) gauge theory, like the original Yang-Mills gauge theory. However, the coupling to quarks selected out only Abelian configurations of the dual potential. Therefore, our results for the $q\bar{q}$ interaction do not depend upon the details of the dual gauge group and should be regarded more as consequences of the general dual superconductor picture rather than of our particular realization of it. The essential feature of this picture is the description of long distance Yang-Mills theory by a dual gauge theory in which all particles become massive via a dual Higgs mechanism.

Appendix A

Notice that

\[ \vec{a}_j = \frac{4}{3} e_j \langle \vec{D}(\vec{z}_j) \rangle_{\text{eff}} \]

can be interpreted as the acceleration of the \( j \)th quark so that eq. (4.17) can be rewritten

\[ V_{Thomas} = -\frac{1}{2} \sum_{j=1}^{2} S_j \cdot (\vec{v}_j \times \vec{a}_j), \]

which is the usual expression obtained from semiclassical considerations. To express \( V_{Thomas} \) in terms of the derivative of the static potential we first note from eq. (4.9) that

\[ \frac{\delta i \log W_{eff}(\Gamma)}{\delta \vec{D}_S(\vec{x})} = \frac{4}{3} \langle \vec{D}(\vec{x}) \rangle_{\text{eff}}. \]

Now, using the fact that

\[ \vec{\nabla}_1 \vec{D}_S(\vec{x}) = -e \nabla(\vec{x} - \vec{z}_1), \]

where \( \vec{\nabla}_1 = \frac{\partial}{\partial \vec{z}_1} \), we have

\[ \vec{R} \frac{dV_0(\vec{R})}{d\vec{R}} = \vec{R} \cdot \vec{\nabla}_1 V_0 \]

\[ = \vec{R} \int d\vec{z} \delta i \frac{\log W_{eff}}{\delta \vec{D}_S(\vec{z})} \cdot \vec{\nabla}_1 \vec{D}_S(\vec{x}) \]

\[ = -e \vec{R} \cdot \int d\vec{z} \frac{4}{3} \langle \vec{D}(\vec{x}) \rangle_{\text{eff}} \delta(\vec{x} - \vec{z}_1) \]

\[ = -e \frac{4}{3} \vec{R} \langle \vec{D}(\vec{z}_1) \rangle_{\text{eff}} \cdot \vec{R}. \]

Now by symmetry, \( \langle \vec{D}(\vec{z}_1) \rangle_{\text{eff}} \) evaluated at the position of a quark must lie along \( \vec{R} \). Hence,

\[ \frac{-4}{3} e \langle \vec{D}(\vec{z}_1) \rangle_{\text{eff}} = \vec{R} \frac{dV_0}{d\vec{R}}. \]

Eq. (A1) then gives \( \vec{a}_1 = -\frac{\vec{R}}{m_1} \frac{\partial V_0}{\partial \vec{R}}, \) so that eq. (A2) gives (4.18).
Appendix B

Here we begin with an alternate form for $V_{\text{Darwin}}$ where $A_\mu$ does not appear explicitly.\(^[4]\)

\[ e \int dx^\mu \langle\!\langle D^\nu F_{\nu \mu}(x) \rangle\!\rangle = \int_{t_1}^{t_2} dt \nabla^2 V_0 \]

\[-ie^2 \int_{t_1}^{t_2} \int \int dx^\mu dx^\mu' \langle\!\langle F_{\mu \nu}(x) F^{\sigma \nu}(x') \rangle\!\rangle - \langle\!\langle F_{\mu \nu}(x) \rangle\!\rangle \langle\!\langle F^{\sigma \nu}(x') \rangle\!\rangle = \]

\[ m(B1) = \int_{t_1}^{t_2} dt \nabla^2 V_0 - ie^2 \int_{t_1}^{t_2} dt \int \int \frac{\delta}{\delta S^{\mu \nu}(z'_j)} \langle\!\langle F^{\sigma \nu}(z'_j) \rangle\!\rangle - \langle\!\langle F^{\sigma \nu}(z'_j) \rangle\!\rangle \frac{\delta \langle\!\langle D_k(z'_j) \rangle\!\rangle_{eff}}{\delta D_{S_k}(z'_j)}. \]

Eq.(4.12) and the relation between $\delta S^{\mu \nu}$ and variations of $G^{\mu \nu}_\lambda$ give

\[ m(B2) = e \int_{t_1}^{t_2} dt \int_{t_1}^{t_2} \frac{\delta}{\delta S^{\mu \nu}(z'_j)} \langle\!\langle F^{\sigma \nu}(z'_j) \rangle\!\rangle = \frac{4e^2}{3} \int_{t_1}^{t_2} dt \int_{t_1}^{t_2} \frac{\delta \langle\!\langle D_k(z'_j) \rangle\!\rangle_{eff}}{\delta D_{S_k}(z'_j)}. \]

Then using eq.(2.21) with $z_2$ replaced by $z_1$ and $e$ by $-e$ we obtain

\[ m(B3) = \int dt V_{\text{Darwin}} = \sum_j \int dt \nabla^2 V_0/8m_j^2 - \frac{4e^2}{3} \sum_j \int_{t_1}^{t_2} dt \int_{t_1}^{t_2} \frac{1}{8m_j^2} \frac{\delta \langle\!\langle D_k(z'_j) \rangle\!\rangle_{eff}}{\delta D_{S_k}(z'_j)}, \]

which gives a second form for $V_{\text{Darwin}}$. The classical approximation to (B3) is obtained by replacing

\[ \frac{\delta \langle\!\langle \bar{D}(z_j) \rangle\!\rangle_{eff}}{\delta D_{S}(z'_j)} \text{ by } \frac{\delta \bar{D}(z_j)}{\delta D_{S}(z'_j)} \delta(t - t'). \]

This yields the expression

\[ m(B4) V_{\text{Darwin}} = \sum_{j=1}^{2} \frac{1}{8m_j^2} \nabla^2 V_0(R) - \frac{4}{3} e^2 \sum_j \frac{1}{8m_j^2} \frac{\delta D_k(z'_j)}{\delta D_{S_k}(z'_j)}. \]

Following the same reasoning that led to eq. (A5) we obtain

\[ m(B5) = \frac{4}{3} e^2 \frac{\delta D_k(z'_1)}{\delta D_{S_k}(z'_1)} = \nabla^2 V_{\text{NP}}(R). \]

(There is no perturbative contribution to the left hand side of (B5).) The second term in (B4) then cancels the non-perturbative part of the first term. Eq. (B4) then becomes

\[ m(B6) V_{\text{Darwin}} = \left( \frac{1}{8m_1^2} + \frac{1}{8m_2^2} \right) \nabla^2 \left( -\frac{4}{34\pi} e^2 \right) = e^2 \delta(z_1 - z_2) \left( \frac{1}{m_1^2} + \frac{1}{m_2^2} \right), \]

which coincides with (6.28).
