Abstract. We perform a systematic WKB expansion to all orders for a one–dimensional system with potential \( V(x) = U_0/\cos^2(\alpha x) \). We are able to sum the series to the exact energy spectrum. Then we show that at any finite order the error of the WKB approximation measured in the natural units of the mean energy level spacing does not go to zero when the quantum number goes to infinity. Therefore we make the general conclusion that the semiclassical approximations fail to predict the individual energy levels within a vanishing fraction of the mean energy level spacing.

In the last years many studies have been devoted to the transition from classical mechanics to quantum mechanics. These studies are motivated by the so-called quantum chaos (see Ozorio de Almeida 1990, Gutzwiller 1990, Casati and Chirikov 1995). An important aspect is the semiclassical quantization formula of the energy levels for integrable and quasi-integrable systems, i.e. the torus quantization initiated by Einstein (1917) and completed by Maslov (1972, 1981). As is well known, the torus quantization is just the first term of a certain $\hbar$-expansion, the so-called WKB expansion, whose higher terms can be calculated with a recursion formula at least for one degree systems (Dunham 1932, Bender, Olaussen and Wang 1977, Voros 1983).

Recently it has been observed by Prosen and Robnik (1993) and also Graffi, Manfredi and Salasnich (1994) that the leading-order semiclassical approximation fails to predict the individual energy levels within a vanishing fraction of the mean energy level spacing. This result has been shown to be true also for the leading (torus) semiclassical approximation by Salasnich and Robnik (1996).

In this paper we analyze a simple one-dimensional system for which we are able to perform a systematic WKB expansion to all orders resulting in a convergent series whose sum is identical to the exact spectrum. For this system we show that any finite order WKB (semiclassical) approximation fails to predict the individual energy levels within a vanishing fraction of the mean energy level spacing.

The Hamiltonian of the system is given by

$$H = \frac{p^2}{2m} + V(x),$$

where

$$V(x) = \frac{U_0}{\cos^2(\alpha x)}.$$  \hspace{1cm} (2)

Of course, the Hamiltonian is a constant of motion, whose value is equal to the total energy $E$. To perform the torus quantization it is necessary to introduce the action variable

$$I = \frac{1}{2\pi} \int p dx = \frac{\sqrt{2m}}{\alpha} (\sqrt{E} - \sqrt{U_0}).$$

The Hamiltonian as a function of the action reads

$$H = \frac{\alpha^2}{2m} I^2 + 2\alpha \sqrt{\frac{U_0}{2m}} I + U_0,$$ \hspace{1cm} (4)
and after the torus quantization

\[ I = (\nu + \frac{1}{2})\hbar, \]  

(5)

where \( \nu = 0,1,2, \ldots \), the energy spectrum is given by

\[ E_{\nu}^{\text{tor}} = A[(\nu + \frac{1}{2}) + \frac{1}{2}B]^2, \]  

(6)

where \( A = a^2\hbar^2/(2m) \) and \( B = \sqrt{8mU_0/}a\hbar). \)

The Schrödinger equation of the system

\[ [-\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + V(x)]\psi(x) = E\psi(x), \]  

(7)

can be solved analytically (as shown in Landau and Lifshitz 1973, Flügge 1971) and the exact energy spectrum is:

\[ E_{\nu}^{\text{ex}} = A[(\nu + \frac{1}{2}) + \frac{1}{2}\sqrt{1+B^2}]^2, \]  

(8)

where \( \nu = 0,1,2, \ldots \). We see that the torus quantization does not give the correct energy spectrum, but it is well known that the torus quantization is just the first term of the WKB expansion. To calculate all the terms of the WKB expansion we observe that the wave function can always be written as

\[ \psi(x) = \exp \left( \frac{i}{\hbar}\sigma(x) \right), \]  

(9)

where the phase \( \sigma(x) \) is a complex function that satisfies the differential equation

\[ \sigma''(x) + \left( \frac{\hbar}{i}\right)\sigma''(x) = 2m(E - V(x)). \]  

(10)

The WKB expansion for the phase is given by

\[ \sigma(x) = \sum_{k=0}^{\infty} \left( \frac{\hbar}{i} \right)^k \sigma_k(x). \]  

(11)

Substituting (11) into (10) and comparing like powers of \( \hbar \) gives the recursion relation \( (n > 0) \)

\[ \sigma_0^\prime = 2m(E - V(x)), \quad \sum_{k=0}^{n} \sigma_k' \sigma_{n-k} + \sigma_n'' = 0. \]  

(12)
The quantization condition is obtained by requiring the single-valuedness of the wave function

$$\int d\sigma = \sum_{k=0}^{\infty} \left( \frac{\hbar}{i} \right)^k \int d\sigma_k = 2\pi \hbar \nu ,$$  \hspace{1cm} (13)$$

where \( \nu = 0, 1, 2, \ldots \) is the quantum number.

The zero order term, which gives the Bohr-Sommerfeld formula, is given by

$$\int d\sigma_0 = 2 \int dx \sqrt{2m(E-V(x))} = 2\pi \hbar \left( \frac{E}{A} - \frac{1}{2} B \right) ,$$  \hspace{1cm} (14)$$

and the first odd term in the series gives the Maslov corrections (Maslov index is equal to 2)

$$\left( \frac{\hbar}{i} \right) \int d\sigma_1 = \left( \frac{\hbar}{i} \right) \frac{1}{4} \ln p|_{\text{contour}} = -\pi \hbar .$$  \hspace{1cm} (15)$$

The zero and first order terms give the equation (6), which is the torus quantization formula for the energy levels (Bohr-Sommerfeld–Maslov). Here we want to analyze the quantum corrections to this formula. We observe that all the other odd terms vanish when integrated along the closed contour because they are exact differentials (Bender, Olaussen and Wang 1977). So the quantization condition (13) can be written

$$\sum_{k=0}^{\infty} \left( \frac{\hbar}{i} \right)^{2k} \int d\sigma_{2k} = 2\pi \hbar (\nu + \frac{1}{2}) ,$$  \hspace{1cm} (16)$$

thus again a sum over even-numbered terms only. The next two non-zero terms are (Narimianov 1995, Bender, Olaussen and Wang 1977, Robnik and Salasnich 1996)

$$\left( \frac{\hbar}{i} \right)^2 \int d\sigma_2 = -\frac{\hbar^2}{2m} \frac{1}{12} \frac{\partial^2}{\partial E^2} \int dx \frac{V^2(x)}{\sqrt{E-V(x)}},$$  \hspace{1cm} (17)$$

$$\left( \frac{\hbar}{i} \right)^4 \int d\sigma_4 = \frac{\hbar^4}{(2m)^{3/2}} \left[ \frac{1}{120} \frac{\partial^3}{\partial E^3} \int dx \frac{V^3(x)}{\sqrt{E-V(x)}} - \frac{1}{288} \frac{\partial^4}{\partial E^4} \int dx \frac{V^2(x) V''(x)}{\sqrt{E-V(x)}} \right].$$  \hspace{1cm} (18)$$
A straightforward calculation of these terms gives (see the Appendix)

\[ \left( \frac{\hbar}{i} \right)^2 \oint d\sigma_2 = -\frac{2\pi \hbar}{4B}, \]  

and

\[ \left( \frac{\hbar}{i} \right)^4 \oint d\sigma_4 = \frac{2\pi \hbar}{16B^3}. \]  

Up to the fourth order in \( \hbar \sim B^{-1} \) the quantization condition reads

\[ E^{(4)}_{\nu} = A[(\nu + \frac{1}{2}) + \frac{1}{2}B + \frac{1}{4B} - \frac{1}{16B^3}]^2. \]  

The first two terms on the right side give the torus quantization formula, and the other two terms are quantum corrections. Higher-order quantum corrections quickly increase in complexity but in this specific case they can be calculated. We first verify by induction, following Bender, Olaussen and Wang (1977), that the solution to (12) has the general form

\[ \sigma_n(x) = (\sigma_0')^{1-3n} P_n(\cos(\alpha x)) \sin f(n)(\alpha x), \]  

where \( f(n) = 0 \) for \( n \) even and \( f(n) = 1 \) for \( n \) odd, and \( P_n \) is a polynomial given by

\[ P_n(\cos(\alpha x)) = \sum_{l=0}^{g(n)} C_{n,l} \cos^{2l-3n}(\alpha x), \]  

with \( g(n) = (3n - 2)/2 \) for \( n \) even and \( g(n) = (3n - 3)/2 \) for \( n \) odd.

The integrals in (16) are performed by substituting \( z = \tan(\alpha x) \). In this way the \( 2k \)-term reduces to

\[ \left( \frac{\hbar}{i} \right)^{2k} \oint d\sigma_{2k} = \left( \frac{\hbar}{i} \right)^{2k} \frac{(2m)^{1/2-3k}}{\alpha} \sum_{l=0}^{3k-1} C_{2k,l} \oint dz \frac{(1 + z^2)^{3k-l-1}}{(E - U_0 - U_0 z^2)^{3k-1/2}}. \]  

We observe that

\[ \oint dz \frac{(1 + z^2)^{3k-l-1}}{(E - U_0 - U_0 z^2)^{3k-1/2}} = \]  

\[ = (-1)^{3k-1} \frac{\Gamma(\frac{1}{2}) \partial^{3k-1}}{\Gamma(3k - \frac{1}{2}) \partial E^{3k-1}} \oint dz \frac{(1 + z^2)^{3k-l-1}}{(E - U_0 - U_0 z^2)^{1/2}}, \]  

where
so the only non-zero term is for \( l = 0 \)

\[
\frac{\partial^{3k-1}}{\partial E^{3k-1}} \int dz \frac{(1 + z^2)^{3k-1}}{(E - U_0 - U_0 z^2)^{1/2}} = \frac{2^{6k-1} \Gamma(3k - 1/2)^2}{U_0^{1/2} \Gamma(6k - 1)} \frac{\partial^{3k-1}}{\partial E^{3k-1}} \beta^{3k-1} = 
\]

\[
= \frac{2^{6k-1}}{U_0^{1/2}} \frac{\Gamma(3k - 1/2)^2}{\Gamma(6k - 1)} \frac{1}{U_0^{3k-1/2}} 2\pi , 
\]

where \( \beta = (E - U_0)/U_0 \). At this stage we obtain

\[
(h \frac{\hbar}{i})^{2k} \int d\sigma_{2k} = (-1)^{5k-1} \hbar^{2k} \left( \frac{2m}{\alpha} \right)^{1/2-3k} \frac{1}{\alpha} C_{2k,0} \frac{1}{U_0^{3k-1/2}} 2\pi . 
\]

Now we need to find the coefficient \( C_{2k,0} \) explicitly. By inserting (22) with (23) in the recursion relation (12) we obtain

\[
\sum_{k=0}^{n} C_{k,0} C_{n-k,0} - (2mU_0 \alpha) C_{n-1,0} = \sum_{k=1}^{n-1} C_{k,0} C_{n-k,0} + 2C_{n,0} - (2mU_0 \alpha) C_{n-1,0} = 0 ,
\]

from which we have

\[
C_{k,0} = \frac{1}{2} \left[ (2m \alpha U_0) C_{k-1,0} - \sum_{j=1}^{k-1} C_{j,0} C_{k-j,0} \right] , \quad C_{0,0} = 1 .
\]

From this equation one shows \( C_{1,0} = m \alpha U_0 \). Further, it easy to show that all higher odd coefficients vanish, \( C_{2k+3,0} = 0 \) for \( k = 0, 1, 2, \ldots \). The solution of this equation for the remaining nonzero even coefficients is given by

\[
C_{2k,0} = (-1)^k (2m U_0 \alpha)^{2k} 2^{-2k} \left( \frac{1}{2} \right) \kappa, 
\]

which can be verified by direct substitution in equation (29) resulting in an identity for half integer binomial coefficients. Then the integral (27) can be written

\[
(h \frac{\hbar}{i})^{2k} \int d\sigma_{2k} = (-1)^k \hbar^{2k} 2\pi \alpha^{3k-1} (2m)^{1/2-k} 2^{-2k} \left( \frac{1}{2} \right) U_0^{k-1/2} = -\frac{1}{2} \left( \frac{1}{2} \right) 2\pi \hbar \frac{2\pi \hbar}{B^{2k-1}} .
\]
In conclusion, the WKB quantization to all orders (16) is

\[
E^{(\infty)}_{\nu} = A\left[(\nu + \frac{1}{2}) + \frac{1}{2} \sum_{k=0}^{\infty} \left(\frac{1}{k}\right) \frac{1}{B^{2k-1}}\right]^2. \tag{32}
\]

Because \( \sum_{k=0}^{\infty} \left(\frac{1}{k}\right) B^{1-2k} = \sqrt{1+B^2} \) we have \( E^{ex}_{\nu} = E^{(\infty)}_{\nu} \), i.e. the WKB series converges to the exact result (8).

Now we can calculate the error in units of the mean level spacing \( \Delta E_{\nu} = E^{ex}_{\nu+1} - E^{ex}_{\nu} \) between the exact level \( E^{ex}_{\nu} \) and its WKB approximation \( E^{(N)}_{\nu} \) to \( N \)th order:

\[
\frac{E^{ex}_{\nu} - E^{(N)}_{\nu}}{\Delta E_{\nu}} = \frac{1}{2} \sum_{k=N+1}^{\infty} \left(\frac{1}{k}\right) \frac{1}{B^{2k-1}}, \quad \text{for } \nu \to \infty. \tag{33}
\]

The limit clearly shows that even for arbitrarily small but finite \( \hbar \) (\( 1 << B < \infty \)), the relative error for any finite WKB approximation becomes constant on increasing \( \nu \), and scales as

\[
\frac{E^{ex}_{\nu} - E^{(N)}_{\nu}}{\Delta E_{\nu}} \sim \frac{1}{2} \left(\frac{1}{N+1}\right) \frac{1}{B^{2N+1}}, \quad B \to \infty. \tag{34}
\]

Note that the limit \( B \to \infty \) is equivalent to the limit \( \hbar \to 0 \).

For our present system we can conclude that to any finite order semiclassical approximation the error measured in units of the mean level spacing remains constant even if the quantum number increases indefinitely, contrary to the naive expectation. This confirms the general statements made by Prosen and Robnik (1993). We have thus provided a clear demonstration that the semiclassical methods cannot predict the individual energy levels (and also their wavefunctions) within a vanishing fraction of the mean energy level spacing. Therefore we cannot expect the semiclassics to correctly describe the fine structure of energy spectra manifested in the short range statistics like the energy level repulsion, which was predicted to be a purely quantum effect (Robnik 1986), later reconfirmed by Berry (1991). On the other hand Prosen and Robnik (1993) have shown that the long range statistics of the energy spectra are very well captured even by the lowest order semiclassical approximation. This is of course compatible with the very important semiclassical theory of delta statistics \( \Delta(L) \) (spectral rigidity) by Berry (1985),
employing the Gutzwiller periodic orbit theory (1990), where agreement with predictions of random matrix theories and with the experimental and numerical data has been obtained at large $L$. Also, Berry and Tabor (1977) have used torus quantization of integrable systems (with many degrees of freedom), predicting the Poissonian (exponential) energy level distribution. Our results show that their result cannot be rigorous, especially as we know some counterexamples of integrable systems with non-Poissonian statistics (Bleher et al. 1993), and also know that their approximation does not take into account the nonperturbative tunneling effects, but it is nevertheless a heuristic argument explaining why typically we do observe Poissonian statistics in classically integrable systems. By typically we mean that the set of exceptions has a small or even vanishing measure.

The conclusion of this paper is that the semiclassical methods are just not good enough (at any order) to describe the fine structure of energy spectra and wavefunctions. Our approach leading to the above conclusion rests upon a systematic WKB expansion for the potential $V(x) = U_0/\cos^2(\alpha x)$ using the technique of Bender, Olsson and Wang (1977). We are able to calculate all orders, the series is convergent and can be summed precisely to the exact result.

Appendix

In this appendix we show how to obtain the formulas (19) and (20). In all integrals of this section the limits of integration are between the two turning points. After substitution $z = \tan(\alpha x)$, we have

$$
\int dx \frac{V'_{\beta}(x)}{\sqrt{E - V(x)}} = \frac{4\alpha U_0^2}{\sqrt{U_0}} \int_{\sqrt{\beta}}^{\sqrt{\beta}} dz \frac{z^2(z^2 + 1)}{\sqrt{\beta - z^2}} = \frac{4\alpha U_0^2}{\sqrt{U_0}} (3\beta^2 + 4\beta \frac{\pi}{8}),
$$

(35)

where $\beta = (E - U_0)/U_0$. In conclusion we have

$$
(h_i)^2 \int d\sigma_2 = \frac{\hbar^2 \alpha \pi}{8\sqrt{2mU_0}} = \frac{2\pi \hbar}{4B},
$$

(36)

with $B = \sqrt{8mU_0/(\alpha \hbar)}$.

To obtain the formula (21) we proceed in the same way.

$$
\int dx \frac{V''_{\beta}(x)}{\sqrt{E - V(x)}} = \frac{4\alpha^3 U_0^2}{\sqrt{U_0}} \int_{\sqrt{\beta}}^{\sqrt{\beta}} dz \frac{(9z^4 + 6z^2 + 1)(z^2 + 1)}{\sqrt{\beta - z^2}} = \frac{4\alpha U_0^2}{\sqrt{U_0}} (45\beta^3 + 90\beta^2 + 56\beta + 16) \frac{\pi}{16},
$$

(37)

From which we obtain

$$
\frac{\partial^3}{\partial E^3} \int dx \frac{V''_{\beta}(x)}{\sqrt{E - V(x)}} = \frac{135\pi \alpha^3 \sqrt{U_0}}{2U_0^2}.
$$

(38)

For the last integral we have

$$
\int dx \frac{V'^2(x)V''_{\beta}(x)}{\sqrt{E - V(x)}} = \frac{8\alpha^3 U_0^2}{\sqrt{U_0}} \int_{\sqrt{\beta}}^{\sqrt{\beta}} dz \frac{z^2(z^2 + 1)(z^2 + 1)^2}{\sqrt{\beta - z^2}} = \frac{8\alpha U_0^2}{\sqrt{U_0}} (105\beta^4 + 280\beta^3 + 240\beta^2 + 60\beta) \frac{\pi}{128},
$$

(39)
from which we obtain

\[
\frac{\partial^4}{\partial E^4} \int dx \frac{V'(x)V''(x)}{\sqrt{E - V(x)}} = \frac{315\pi \alpha^3 \sqrt{U_0}}{2U_0^2} .
\] (40)

In conclusion we have

\[
\left( \frac{\hbar}{\imath} \right)^4 \int d\sigma_4 = \frac{\hbar^4}{(2m)^{3/2} U_0^2} \left[ \frac{1}{120} \frac{135}{2} - \frac{1}{288} \frac{315}{2} \right] = \\
= \frac{\hbar^4 \alpha^3 \pi \sqrt{U_0}}{64(2m)^{3/2} U_0^2} = \frac{2\pi \hbar}{16B^3} .
\] (41)
