\textbf{ABSTRACT}

We analyze charm meson semileptonic $D \rightarrow V l \nu_l$ and $D \rightarrow P l \nu_l$ and nonleptonic $D \rightarrow PV$, $D \rightarrow PP$ and $D \rightarrow VV$ decays within a model which combines the heavy quark effective Lagrangian and chiral perturbation theory.

\textsuperscript{1}Contributed paper for LEPTON - PHOTON INTERACTIONS, Hamburg, Germany, 28 July - 1 August 1997
I. INTRODUCTION

The experimental data for the semileptonic decays of D mesons are unfortunately not good enough to clearly determine the $q^2$ dependence of the form factors. What is known experimentally, apart from the branching ratios, are the form factors at one kinematical point, assuming a pole-type behavior for all the form factors. This assumption seems reasonable, but within heavy quark effective theory (HQET) the kinematic constraint on the form factors at $q^2 = 0$ cannot be satisfied unless a special relation is imposed between the pole masses and residues. Recently we have developed a model for the semileptonic decays $D \rightarrow Vl\nu_l$ and $D \rightarrow Pl\nu_l$, where $P$ and $V$ are light $J^{P} = 0^{-}$ and $1^{-}$ mesons, respectively [1]. This model combines the heavy quark effective theory and the chiral Lagrangians. HQET is valid at a small recoil momentum [2, 3] and can give definite predictions for heavy to light ($D \rightarrow V$ or $D \rightarrow P$) semileptonic decays in the kinematic region with large momentum transfer $q^2$ to the lepton pair. Unfortunately, it cannot predict the $q^2$ dependence of the form factors [2, 3]. For these reasons, we have modified the Lagrangian for heavy and light pseudoscalar and vector mesons given by the HQET and chiral symmetry [2]. Our model [1] gives a natural explanation of the pole-type form factors in the whole $q^2$ range, and it determines which form factors have a pole-type or a constant behavior, confirming the results of the QCD sum rules analysis [4]. To demonstrate that this model works well, we have calculated the decay widths in all measured charm meson semileptonic decays [1]. The model parameters were determined by the experimental values of two measured semileptonic decay widths. The predictions of the model are in good agreement with the remaining experimental data on semileptonic decays.

The nonleptonic D meson decays are challenging to understand theoretically (see e.g. [5] and references therein). The short distance effects are now well understood [6], but the nonperturbative techniques required for the evaluation of certain matrix elements are based on approximate models. Often the factorization approximation is used (see e.g. [5] and references therein). The amplitude for the nonleptonic weak decay is then considered as a sum of the "spectator" contribution and the "annihilation" contribution, the direct annihilation of the initial heavy meson. In the determination of the "spectator" contribution one uses the knowledge of the hadronic matrix
elements calculated in D meson semileptonic decays. Another problem in the 
analysis of nonleptonic D meson decays is the final state interactions (FSI) 
[7, 8, 9, 10, 11, 12]. These arise from the interference of different isospin 
states or the presence of intermediate resonances, and both spectator and 
annihilation amplitudes can be affected. The FSI are especially important 
for the annihilation contribution, which can often be successfully described 
by the dominance of nearby scalar or pseudoscalar resonances [7, 8, 9, 10].
The effective model developed to describe the \( D \to V(P)l\bar{\nu}_l \) decay widths [1] 
contains only light vector and pseudoscalar final states and, therefore, is not 
applicable to the annihilation amplitudes. Consequently, in the present paper 
we apply this effective model to analyze only those \( D \to PV, \ D \to PP, \) and 
\( D \to VV \) decays in which the annihilation amplitude is absent or negligible. 
Other FSI might arise as a result of elastic or inelastic rescattering. In this 
case, the two body nonleptonic D meson decay amplitudes can be written in 
terms of isospin amplitudes and strong interaction phases [13]. As usual, we 
assume that the important contributions to FSI are included in these phases. 
In fact, we will avoid the effects of the FSI strong interaction phases by 
considering only the D meson decay modes in which the final state involves 
only a single isospin. Our analysis then includes the decays \( D^+ \to K^{*0}\pi^+, \ D^+ \to \rho^+K^0, \ D^+ \to \bar{K}^0\pi^+, \ D^+ \to \bar{K}^{*0}\rho^+, \ D^+ \to \Phi\pi^+, \ D^+_s \to \Phi\rho^+, \ D^0 \to \Phi\omega^0, \ D^0 \to \Phi\eta, \ D^+ \to \rho^+\eta(\eta') \) and \( D^0 \to \omega^0\eta(\eta') \).

To evaluate the spectator graphs for nonleptonic decays we use the form 
factors for the \( D \to V \) and \( D \to P \) weak decays, calculated for the semilep-
tonic decays [1]. This explores how well their particular \( q^2 \) behavior also 
explains the nonleptonic decay amplitudes. At the same time the analysis 
of the nonleptonic decays enables us to choose between different solutions 
for the model parameters found in the semileptonic decays, determining the 
set of the solutions which are in the best agreement with the experimental 
results for the nonleptonic decay widths. Moreover, we obtain a value for 
the parameter \( \beta \), which can not be determined from the semileptonic decay 
alone, but enters in the nonleptonic decays.

The paper is organized as follows. In Sec. II we present the effective 
Lagrangian for heavy and light pseudoscalar and vector mesons, determined 
by the requirements of HQET and chiral symmetry. In Sec. III we present 
the results for the \( D \to Vl\bar{\nu}_l, \ D \to Pl\bar{\nu}_l \) decays [1]. In Sec. IV we analyze the 
nonleptonic decay widths. Finally, a short summary of the results is given 
in Sec. V.
II. THE HQET AND CHPT LAGRANGIAN FOR $D \to V(P) l \nu$

We incorporate in our Lagrangian both the heavy flavour $SU(2)$ symmetry, and the $SU(3)_L \times SU(3)_R$ chiral symmetry, spontaneously broken to the diagonal $SU(3)_V$ [1] (and references therein), which can be used for the description of heavy and light pseudoscalar and vector mesons. The light degrees of freedom are described by the $3 \times 3$ Hermitian matrices

$$\Pi = \begin{pmatrix}
\frac{\pi^0}{\sqrt{2}} + \frac{\eta_8}{\sqrt{6}} + \frac{\eta_0}{\sqrt{3}} & \pi^+ & K^+ \\
-\frac{\pi^0}{\sqrt{2}} + \frac{\eta_8}{\sqrt{6}} + \frac{\eta_0}{\sqrt{3}} & K^0 & -\frac{2}{\sqrt{6}}\eta_8 + \frac{\eta_0}{\sqrt{3}} \\
K^- & \bar{K}^0 & \frac{2}{\sqrt{6}}\eta_8 + \frac{\eta_0}{\sqrt{3}}
\end{pmatrix}, \quad (1)$$

and

$$\rho_\mu = \begin{pmatrix}
\rho^{\mu_0+\omega_\mu}_{\sqrt{2}} & \rho^{\mu_+}_{\sqrt{2}} & K^{\ast+}_{\mu} \\
-\rho^{\mu_0+\omega_\mu}_{\sqrt{2}} & K^{\ast0}_{\mu} & -\Phi_{\mu} \\
K^{\ast-}_{\mu} & \bar{K}^{\ast0}_{\mu} & \Phi_{\mu}
\end{pmatrix} \quad (2)$$

for the pseudoscalar and vector mesons, respectively. The mass eigenstates are defined by $\eta = \eta_8 \cos \theta_P - \eta_0 \sin \theta_P$ and $\eta' = \eta_8 \sin \theta_P + \eta_0 \cos \theta_P$, where $\theta_P = (-20 \pm 5)^\circ$ [14] is the $\eta - \eta'$ mixing angle. The matrices (1) and (2) are conveniently written in terms of

$$u = \exp\left(\frac{i \Pi}{f}\right), \quad (3)$$

where $f$ is the pseudoscalar decay constant, and

$$\hat{\rho}_\mu = \frac{i g_V}{\sqrt{2}} \rho_\mu, \quad (4)$$

where $g_V = 5.9$ is given by the values of the vector masses since we assume the exact vector dominance [1]. Introducing the vector and axial currents $V_\mu = \frac{1}{2}(u^\dagger \partial_\mu u + u \partial_\mu u^\dagger)$ and $A_\mu = \frac{1}{2}(u^\dagger \partial_\mu u - u \partial_\mu u^\dagger)$ and the gauge field
tensor $F_{\mu\nu}(\hat{\phi}) = \partial_\mu \hat{\phi}_\nu - \partial_\nu \hat{\phi}_\mu + [\hat{\phi}_\mu, \hat{\phi}_\nu]$ the light meson part of the strong Lagrangian can be written as

$$\mathcal{L}_{\text{light}} = - \frac{f^2}{2} \{ \text{tr}(\mathcal{A}_\mu \mathcal{A}^\mu) + 2 \text{tr}[(\mathcal{V}_\mu - \hat{\phi}_\mu)^2] \} + \frac{1}{2g_5^2} \text{tr}[F_{\mu\nu}(\hat{\phi})F^{\mu\nu}(\hat{\phi})].$$

Both the heavy pseudoscalar and the heavy vector mesons are incorporated in the $4 \times 4$ matrix

$$H_a = \frac{1}{2} (1 + \gamma^5) (D^*_a \gamma^\mu - D_a \gamma_5),$$

where $a = 1, 2, 3$ is the $SU(3)_V$ index of the light flavours and $D^*_a$ and $D_a$ annihilate a spin 1 and spin 0 heavy meson $c\bar{q}_a$ of velocity $v$, respectively. They have a mass dimension $3/2$ instead of the usual 1, so that the Lagrangian is explicitly mass independent in the heavy quark limit $m_c \to \infty$. Defining

$$\bar{H}_a = \gamma^0 H_a^\dagger \gamma^0 = (D^*_a \gamma^\mu + D_a^\dagger \gamma_5) \frac{1}{2} (1 + \gamma^5),$$

we can write the leading order strong Lagrangian as

$$\mathcal{L}_{\text{even}} = \mathcal{L}_{\text{light}} + i \text{Tr}(H_a v_\mu (\partial^\mu + \gamma^\mu) \bar{H}_a) + ig \text{Tr}[H_b \gamma_\mu \gamma_5 (\mathcal{A}_a^\mu)_{ba} \bar{H}_a] + i \beta \text{Tr}[H_b v_\mu (\mathcal{V}_\mu - \hat{\phi}_\mu)_{ba} \bar{H}_a] + \frac{\beta^2}{4f^2} \text{Tr}(\bar{H}_b H_a \bar{H}_a H_b).$$

This Lagrangian contains two unknown parameters, $g$ and $\beta$, which are not determined by symmetry arguments, and must be determined empirically. This is the most general even-parity Lagrangian of leading order in the heavy quark mass ($m_Q \to \infty$) and the chiral symmetry limit ($m_q \to 0$ and the minimal number of derivatives).

We will also need the odd-parity Lagrangian for the heavy meson sector. The lowest order contribution to this Lagrangian is given by
\[ \mathcal{L}_{\text{odd}} = i\lambda Tr[H_a \sigma_{\mu\nu} F^{\mu\nu}(\hat{\rho})_{ab} \bar{H}_b]. \] (9)

The parameter \( \lambda \) is free, but we know that this term is of the order \( 1/\Lambda_\chi \) with \( \Lambda_\chi \) being the chiral perturbation theory scale.

### III. FORM FACTORS IN \( D \to V/P\nu\ell \) DECAYS

For the semileptonic decays the weak Lagrangian is given at the quark level by the current - current Fermi interaction

\[ \mathcal{L}_{\text{eff}}(\Delta C = \Delta S = 1) = -\frac{G_F}{\sqrt{2}}[i\gamma_\mu(1 - \gamma_5)\nu_l \bar{s}^' \gamma^\mu(1 - \gamma_5)c] \] (10)

where \( G_F \) is the Fermi constant, and \( s' = s\cos\theta_C + d\sin\theta_C, \theta_C \) being the Cabibbo angle.

At the meson level we assume that the weak current transforms as \((\bar{3}_L, 1_R)\) under chiral \( SU(3)_L \times SU(3)_R \) and is linear in the heavy meson fields. In our calculation of the \( D \) meson semileptonic decays to leading order in both \( 1/M \) and the chiral expansion we have shown that the weak current is [1]

\[
J_a^\mu = \frac{1}{2} \ i\alpha Tr[\gamma^\mu(1 - \gamma_5)H_b \bar{u}_b^a] \\
+ \ \alpha_1 Tr[\gamma_5 H_b(\hat{\rho}^\mu - V^\mu)_{bc} \bar{u}_c^a] \\
+ \ \alpha_2 Tr[\gamma^\mu \gamma_5 H_b \nu_{a}(\hat{\rho}^\alpha - V^\alpha)_{bc} \bar{u}_c^a] + ..., \] (11)

where \( \alpha = f_D \sqrt{m_D} \) [3]. The \( \alpha_1 \) term was first considered in [2]. We found [1] that the \( \alpha_2 \) gives a contribution of the same order in \( 1/M \) and the chiral expansion as the term proportional to \( \alpha_1 \).

The \( H \to V \) and \( H \to P \) current matrix elements can be quite generally written as

\[
< V_{(i)}(\epsilon, p')|(V - A)^\mu|H(p) > = -\frac{2V^{(i)}(q^2)}{m_H + m_{V(i)}} \epsilon^*_{\nu\alpha\beta} \epsilon_{\nu\alpha\beta} \epsilon_{\nu\alpha\beta}
\]
$$-i\epsilon^* \cdot q \frac{2m_{V(i)}}{q^2} q_\mu A_0^{(i)}(q^2) + i(m_H + m_{V(i)})(\epsilon_\mu - \frac{\epsilon^* \cdot q}{q^2} q_\mu) A_1^{(i)}(q^2)$$

$$- \frac{i\epsilon^* \cdot q}{m_H + m_{V(i)}} [(p + p')_\mu - \frac{m_H^2 - m_{V(i)}^2}{q^2} q_\mu] A_2^{(i)}(q^2) ,$$

(12)

and

$$< P(i) (p') | (V - A)_\mu | H(p) > = [(p + p')_\mu - \frac{m_H^2 - m_{P(i)}^2}{q^2} q_\mu] F_1^{(i)}(q^2)$$

$$+ \frac{m_H^2 - m_{P(i)}^2}{q^2} q_\mu F_0^{(i)}(q^2) ,$$

(13)

where, $q = p - p'$ is the exchanged momentum and the index $(i)$ specifies the particular final meson, $P$ or $V$. In order that these matrix elements be finite at $q^2 = 0$, the form factors must satisfy the relations

$$A_0(0) + \frac{m_H + m_{V}}{2m_{V}} A_1(0) - \frac{m_H - m_{V}}{2m_{V}} A_2(0) = 0 .$$

(14)

$$F_1(0) = F_0(0) .$$

(15)

and, therefore, are not free parameters.

In order to extrapolate the amplitude from the zero recoil point to the rest of the allowed kinematical region we have made a very simple, physically motivated, assumption: the vertices do not change significantly, while the propagators of the off-shell heavy mesons are given by the full propagators $1/(p^2 - m^2)$ instead of the HQET propagators $1/(2mv \cdot k)$ [1]. With these assumptions we are able to incorporate the following features: the HQET prediction almost exactly at the maximum $q^2$; a natural explanation for the pole-type form factors when appropriate; and predictions of flat $q^2$ behaviour for the form factors $A_1$ and $A_2$, which has been confirmed in the QCD sum-rule analysis of [4].

Finally, we include $SU(3)$ symmetry breaking by using the physical masses and decay constants shown in Table 1 of ref. [1]. The decay constants for the $\eta$ and $\eta'$ were taken from [15], for the light vector mesons from [9] and for the $D$ mesons from [16], [17] and [18].

The relevant form factors for $D \rightarrow V$ decays defined in (12) calculated in our model [1], are
\[
\frac{1}{K_{V(i)}} \left( \right)^{(i)}(q^2) = \left( m_H + m_{V(i)} \right) \left( \frac{2 m_{H'(-i)}}{m_H} \right)^{\frac{1}{2}} \frac{m_{H'(-i)}}{q^2 - m_{H'(-i)}^2} f_{H'(-i)} \lambda \frac{g_V}{\sqrt{2}} \tag{16}
\]

\[
\frac{1}{K_{V(i)}} A_0^{(i)}(q^2) = \left[ \frac{1}{m_{V(i)}} \left( \frac{m_{H'(-i)}}{m_H} \right)^{\frac{1}{2}} \frac{q^2}{q^2 - m_{H'(-i)}^2} f_{H'(-i)} \beta \right. \\
\left. + \frac{\sqrt{m_H}}{m_{V(i)}} \alpha_1 - \frac{1}{2} \frac{q^2 + m_H^2 - m_{V(i)}^2}{m_H^2} \frac{\sqrt{m_H}}{m_{V(i)}} \alpha_2 \right] \frac{g_V}{\sqrt{2}}, \tag{17}
\]

\[
\frac{1}{K_{V(i)}} A_1^{(i)}(q^2) = -\frac{2\sqrt{m_H}}{m_H + m_{V(i)}} \alpha_1 \frac{g_V}{\sqrt{2}} \tag{18}
\]

and

\[
\frac{1}{K_{V(i)}} A_2^{(i)}(q^2) = \left[ -\frac{m_H + m_{V(i)}}{m_H \sqrt{m_H}} \alpha_2 \right] \frac{g_V}{\sqrt{2}}, \tag{20}
\]

where the pole mesons and the constants $K_{V(i)}$, which contribute to the corresponding processes $D \to PV$ and $D \to V_{(1)}V_{(2)}$ are given in [1].

We determined the three parameters $(\lambda, \alpha_1, \alpha_2)$ in [1] using the three measured values of helicity amplitudes $\Gamma/\Gamma_{TOT} = 0.048 \pm 0.004$, $\Gamma_L/\Gamma_T = 1.23 \pm 0.13$ and $\Gamma_+ / \Gamma_- = 0.16 \pm 0.04$ for the process $D^+ \to \bar{K}^* l^+ l_l$, taken from the Particle Data Group average of all the data [14]. The parameter $\beta$ could not be determined from this decay rate, since $A_0(q^2)$ cannot be observed in the semileptonic decays.

The model parameters appear linearly in the form factors (16)-(20), so the polarized decay rates $\Gamma_0$, $\Gamma_+$ and $\Gamma_-$ are quadratic functions of them. For this reason there are 8 sets of solutions for the three parameters $(\lambda, \alpha_1, \alpha_2)$. It was found from the analysis of the strong decays $D^* \to D \pi$ and electromagnetic decays $D^* \to D \gamma$ [19], that the parameter $\lambda$ has the same sign as the parameter $\lambda'$, which describes the contribution of the magnetic moment of the heavy (charm) quark. In the heavy quark limit we have $\lambda' = -1/(6m_c)$. Assuming that the finite mass effects are not so large as to change the sign, we find that $\lambda < 0$. Therefore only four solutions remain. They are shown in Table 1.

The calculated branching ratios and polarization variables for the other semileptonic decays of the type $D \to V$ are in agreement with all the known experimental data [1] (see Table 2).
In our approach the form factors for $D \to P$ decays are given by [1]

\[ \frac{1}{K_{P(i)}} F_1^{(i)}(q^2) = \frac{1}{f_{P(i)}} \left( -\frac{f_H}{2} + g f_{H^*(i)} \frac{m_{H^{*+}(i)} \sqrt{m_H m_{H^{*+}(i)}}}{q^2 - m_{H^{*+}(i)}^2} \right), \]  

\[ \frac{1}{K_{P(i)}} F_0^{(i)}(q^2) = \frac{1}{f_{P(i)}} \left( -\frac{f_H}{2} - g f_{H^*(i)} \sqrt{\frac{m_H}{m_{H^{*+}(i)}}} \right) + \frac{q^2}{m_H^2 - m_{P(i)}^2} \left( -\frac{f_H}{2} + g f_{H^*(i)} \sqrt{\frac{m_H}{m_{H^{*+}(i)}}} \right). \]  

where the pole mesons and the constants $K_{P(i)}$, which contribute to the corresponding processes $D \to PV$ and $D \to P(1)P(2)$ are given in in [1]. We neglected the lepton mass, so the form factor $F_0$, which multiplies $q^\mu$, did not contribute to the decay width.

Using the best known experimental branching ratio - $B[D^0 \to K^- l^+ \nu_l] = (3.68 \pm 0.21)\%$ [14], we found two solutions for $g$:

SOL. 1 : $g \equiv g_\geq = 0.15 \pm 0.08$ ,

SOL. 2 : $g \equiv g_\leq = -0.96 \pm 0.18$ .

The quoted error for $g_\geq$ is mainly due to the uncertainty in the value $f_D$, while the quoted error for $g_\leq$ is mainly due to the uncertainty in $f_{D^*}$. Unfortunately we were not able to choose between the two possible solutions for $g$ in (23).

the branching ratios for $D \to P$ transitions are presented in Table 3.

IV. NONLEPTONIC DECAYS

The effective Hamiltonian for charm decays is given by

\[ H_w = \frac{G_F}{\sqrt{2}} V_{c \bar{q}} V_{uj}^* \left\{ a_1(\bar{u}\Gamma_\mu q_j)(\bar{q}_i\Gamma^\mu c) + a_2(\bar{u}\Gamma_\mu c)(\bar{q}_i\Gamma^\mu q_j) \right\} \]  

where $V_{qfq'}$ is an element of the CKM matrix, $i$ and $j$ stand for $d$ or $s$ quark flavours, $\Gamma_\mu = \gamma_\mu (1 - \gamma^5)$, and $a_1$ and $a_2$ are the Wilson coefficients:

\[ a_1 = 1.26 \pm 0.04 \quad a_2 = -0.51 \pm 0.05 . \]
These values are taken from [6, 11, 12] and they are in agreement with the next-to-leading order calculation [6]. The factorization approach in two body nonleptonic decays means one can write the amplitude in the form

$$<AB|\bar{q}_i \Gamma_{\mu} q_j \bar{q}_k \Gamma^\mu c|D> = <A|\bar{q}_i \Gamma_{\mu} q_j|0><B|\bar{q}_k \Gamma^\mu c|D> + <B|\bar{q}_i \Gamma_{\mu} q_j|0><A|\bar{q}_k \Gamma^\mu c|D> + <AB|\bar{q}_i \Gamma_{\mu} q_j|0><0|\bar{q}_k \Gamma^\mu c|D>.$$  \ (26)

In our calculations we take into account only the first two contributions. The last one is the annihilation contribution, which is absent or negligible in the particular decay modes we consider. In other decays this contribution was found to be rather important [11, 12, 9]. It was pointed out in [11, 12, 8, 10] that the simple dominance by the lightest scalar or pseudoscalar mesons in $$<AB|\bar{q}_i \Gamma_{\mu} q_j|0>$$ can not explain the rather large contribution present in some of the nonleptonic decays, which we will not consider. Our model [1], being rather poor in the number of resonances, is applicable to the analysis of the spectator amplitudes, but not the annihilation contributions.

We will use the following definitions of the light meson and the heavy meson couplings

$$<P(p)|j_\mu|0> = -i f_P p_\mu, \quad <V(p, \epsilon^*)|j_\mu|0> = m_V f_V \epsilon^{*\mu}, \quad <0|j_\mu|D(P)> = -i f_D m_D v_\mu, \quad \text{and} \quad <0|j_\mu|D^*(\epsilon, P)> = im_D f_D \epsilon^{\mu}.$$  

Then using (12) and (13) we can write the amplitude for the nonleptonic decay $D \to PV$ processes as

$$M(D(p) \to PV(\epsilon^*)) = \frac{G_F}{\sqrt{2}} \epsilon^* \cdot p \left[ 2m_V [-w_V K_V f_P A_0(m_P^2)] + w_P K_P f_V F_1(m_V^2) \right]  \ (27)$$

The factors $w_V$, $w_P$, $K_V$ and $K_P$ are given in [5].

The $D \to P_1 P_2$ decay amplitude is

$$M(D(p) \to P_1(1) P_2(2)) = \frac{G_F}{\sqrt{2}} \left[ -iw_1 K_{P(1)} f_{P(2)} \left( m_H^2 - m_{P(1)}^2 \right) F^{(1)}(m_P^2) \right. \left. - iw_2 K_{P(2)} f_{P(1)} \left( m_H^2 - m_{P(2)}^2 \right) F^{(2)}(m_P^2) \right]  \ (28)$$

The factors $w_1$, $w_2$, $K_{P(1)}$ and $K_{P(2)}$ are presented in [5].

Finally, we find the $D \to V_1(1) V_2(2)$ decay amplitude to be

$$M(D(p) \to V_1(1)(p_1, \epsilon_1), V_2(2)(p_2, \epsilon_2)) = \ (29)$$
From (27) and (17) it can easily be seen that $\beta$ the predictions for the nonleptonic decay rates are not very sensitive to $V$ for the decays which depend only on the form factors of the values for $g$. However, although the uncertainties of the predictions are quite large, they are mostly due to the calculated errors in $\lambda$. The factors $\lambda$ (23) and four solutions for the parameters (Table 1). The calculated nonleptonic decay amplitudes depend on the choice of these parameters.

In order to avoid the strong interaction final state effects in the interference between different final isospin states we analyze decays in which the final state involves only a single isospin. This occurs when there is an isospin zero difference between different final isospin states we analyze decays in which the final particle in the final state (the state involves only a single isospin. For example, $D^+ \to K^0\pi^+$, $D^+ \to \rho^+K^0$, $D^+ \to K^0\pi^+$ and $D^+ \to K^0\rho^+$ with $|I,J_3>=|3/2,3/2>$).

Our analysis of semileptonic decays $D \to V(P)\nu_l$ [1] left some ambiguity in the choice of the model parameters: there are two values of $g$, $(g_< , g_>)$ (23) and four solutions for the parameters $(\lambda, \alpha_1, \alpha_2)$ (Table 1). The calculated nonleptonic decay amplitudes depend on the choice of these parameters. However, although the uncertainties of the predictions are quite large, they are mostly due to the calculated errors in $\langle g_-, g_\rangle$ (23), which is in turn due to the uncertainty in $f_D$ and $f_{D^*}$. The only parameter that is not constrained by the semileptonic decay data is the parameter $\beta$ in the form factor $A_0$, but the predictions for the nonleptonic decay rates are not very sensitive to $\beta$. From (27) and (17) it can easily be seen that $\beta$ appears multiplied by $m^2_D$ in the $D \to PV$ decay width and is only significant for the decays $D \to PV$, where $P$ is $K$, $\eta$ or $\eta'$.

First we discuss the results for the decay amplitudes which depend only on the form factors $F_0$ and $F_1$ and consequently only on the parameter $g$: namely, $D^+ \to K^0\pi^+$, $D^+ \to \Phi\pi^+$, $D^+_s \to \rho^+\eta(\eta')$, $D^0 \to \Phi\eta$ and $D^0 \to \Phi\pi^0$. The comparison with the experimental data does not exclude either of the values for $g$, $g_-$ or $g_+$ [5]. Next, we summarize the results obtained for the decays which depend only on the form factors $V$, $A_0$, $A_1$ and $A_2$, and consequently only on the parameters $(\lambda, \alpha_1, \alpha_2)$; namely, $D^+_s \to \Phi\pi^+$,
\( D_s^+ \to \Phi \rho^+ \), \( D^0 \to \Phi \rho^0 \) and \( D^+ \to \bar{K}^* \rho^+ \). The decay \( D_s^+ \to \Phi \pi^+ \) depends also on the parameter \( \beta \), but this dependence is very slight, since the light pseudoscalar meson in the final state is a \( \pi \).

The results for all sets are in rather good agreement with the experimental data, with the exception of \( D^0 \to \Phi \rho^0 \), which we do not understand.

In addition to the above two types of nonleptonic decays, there are two measured branching ratios for \( D^+ \to \bar{K}^* \rho^+ \) and \( D^+ \to \rho^+ \bar{K}^0 \). Their decay amplitudes depend on both \( g \) and the parameters \( \lambda \), \( \alpha_1 \), \( \alpha_2 \). The branching ratio for \( D^+ \to \bar{K}^* \pi^+ \), which is not sensitive to \( \beta \) since the \( \pi \) mass is small, excludes the parameter \( g_\lambda \), the sets II and IV, and prefers \( g = g_\lambda > 0.15 \pm 0.08 \) and the set I.

From the \( D^+ \to \rho^+ \bar{K}^0 \) decay, which has \( K \) pseudoscalar meson in the final state, one can then estimate the parameter \( \beta \). Unfortunately, this decay has a considerable experimental error, \( BR = (6.6 \pm 2.5)\% \) [14], which results in large error in \( \beta \):

\[
\beta = 3.5 \pm 3 .
\]  

The predictions for the branching ratios for the possible decays are presented in Table 4 assuming set I for \( \lambda \), \( \alpha_1 \) and \( \alpha_2 \), \( g = g_\lambda = 0.15 \pm 0.08 \) and \( \beta = 3.5 \pm 3 \). The quoted errors are due to the uncertainties in the model parameters, mainly \( g \).

VI. SUMMARY

We have proposed a method to include the light vector meson resonances in the weak currents using HQET and CHPT. Instead of the propagators used in HQET we have used full propagators for the intermediate heavy meson states. In this way we obtain a pole-type behavior of the form factors for the matrix elements of the vector currents, and a constant behavior of the form factors of the axial current. The calculated branching ratios are in agreement with the experimental results. We have predicted the other semileptonic decays that have not yet been observed. In addition we have calculated the branching ratios for the nonleptonic decay modes \( D \to PV \), \( D \to P_1 P_2 \) and \( D \to V_1 V_2 \) in which the annihilation contribution is absent or negligible, and
in which the final state involves only a single isospin in order to avoid the effects of strong interaction phases. Factorization of the matrix elements was then assumed and we used the effective model developed to describe the semileptonic decays $D \rightarrow V(P)l\nu_l$ to calculate the nonleptonic matrix elements. We reproduced the experimental results for branching ratios for the $D^+ \rightarrow \bar{K}^*0\pi^+$, $D^+ \rightarrow \rho^+\bar{K}^0$, $D^+_s \rightarrow \Phi\pi^+$, $D^+_s \rightarrow \rho^+\eta$, $D^+ \rightarrow \bar{K}^0\pi^+$, $D^+_s \rightarrow \Phi\rho^+$ and $D^+ \rightarrow \bar{K}^*0\rho^+$ decays, albeit within substantial uncertainties. We also determined the set of parameters $\lambda$, $\alpha_1$, $\alpha_2$ and $g$, which gave the best agreement with the experimental results and used this set of parameters to estimate the parameter $\beta$ from the branching ratio for $D^+ \rightarrow \rho^+\bar{K}^0$. We then made the predictions for a number of nonleptonic decay rates which have not yet been measured.

References

[1] B. Bajc, S. Fajfer and R.J. Oakes Phys. Rev. D 53, 4957 (1996). Note that the expressions for the form factors $A_0$ and $F_0$ have been corrected in the present paper [Eqn. (17) and (22)]. The corrected form factors do not change any results in this reference because the form factors $A_0$ and $F_0$ do not contribute to the semileptonic decay widths since the electron mass is negligible.
