Abstract

To establish the Higgs mechanism $sui generis$ experimentally, the self-energy potential of the Higgs field must be reconstructed. This task requires the measurement of the trilinear and quadrilinear self-couplings, as predicted, for instance, in the Standard Model or in supersymmetric theories. The couplings can be probed in multiple Higgs production at high-luminosity $e^+e^-$ linear colliders. Complementing earlier studies to develop a coherent picture of the trilinear couplings, we have analyzed the production of pairs of neutral Higgs bosons in all relevant channels of double Higgs-strahlung, associated multiple Higgs production and $WW/ZZ$ fusion to Higgs pairs.
1. Introduction

The Higgs mechanism [1] is a cornerstone in the electroweak sector of the Standard Model (SM) [2]. The electroweak gauge bosons and the fundamental matter particles acquire masses through the interaction with a scalar field. The self-interaction of the scalar field leads to a non-zero field strength $v = (\sqrt{2}G_F)^{-1/2} = 246$ GeV in the ground state, inducing the spontaneous breaking of the electroweak SU(2)$_L \times$ U(1)$_Y$ symmetry down to the electromagnetic U(1)$_{EM}$ symmetry.

To establish the Higgs mechanism $sui generis$ experimentally, the characteristic self-energy potential of the Standard Model,

$$V = \lambda \left[ |\varphi|^2 - \frac{1}{2}v^2 \right]^2$$

with a minimum at $\langle \varphi \rangle_0 = v/\sqrt{2}$, must be reconstructed once the Higgs particle will have been discovered. This experimental task requires the measurement of the trilinear and quadrilinear self-couplings of the Higgs boson. The self-couplings are uniquely determined in the Standard Model by the mass of the Higgs boson which is related to the quadrilinear coupling $\lambda$ by $M_H = \sqrt{2}\lambda v$. Introducing the physical Higgs field $H$,

$$\varphi = \frac{1}{\sqrt{2}} \left( \begin{array}{c} 0 \\ v + H \end{array} \right)$$

the trilinear vertex of the Higgs field $H$ is given by the coefficient

$$\lambda_{HHH} = 3M_H^2/M_Z^2$$

in units of $\lambda_0 = M_H^2/v$, while the quadrilinear vertex carries the coefficient

$$\lambda_{HHHH} = 3M_H^2/M_Z^4$$

in units of $\lambda_0^2$; numerically $\lambda_0 = 33.8$ GeV. For a Higgs mass $M_H = 110$ GeV, the trilinear coupling amounts to $\lambda_{HHH}\lambda_0/M_Z = 1.6$ for a typical energy scale $M_Z$, whereas the quadrilinear coupling $\lambda_{HHHH}\lambda_0^2 = 0.6$ is suppressed with respect to the trilinear coupling by a factor close to the size of the weak gauge coupling.

The trilinear Higgs self-coupling can be measured directly in pair-production of Higgs particles at hadron and high-energy $e^+e^-$ linear colliders. Several mechanisms that are sensitive to $\lambda_{HHH}$ can be exploited for this task. Higgs pairs can be produced through double Higgs-strahlung off $W$ or $Z$ bosons [3,4], $WW$ or $ZZ$ fusion [4–8]; moreover through gluon-gluon fusion in $pp$ collisions [9–11] and high-energy $\gamma\gamma$ fusion [4,5,12] at photon colliders. The two main processes at $e^+e^-$ colliders are double Higgs-strahlung and $WW$ fusion:

$$e^+e^- \rightarrow ZHH$$

$$WW$$

$$\bar{\nu}_e\nu_eHH$$

\[5\]
double Higgs-strahlung: $e^+ e^- \rightarrow ZHH$

WW double-Higgs fusion: $e^+ e^- \rightarrow \bar{\nu}_e \nu_e HH$

Figure 1: Processes contributing to Higgs-pair production in the Standard Model at $e^+ e^-$ linear colliders: double Higgs-strahlung and WW fusion (generic diagrams).

The $ZZ$ fusion process of Higgs pairs is suppressed by an order of magnitude since the electron-$Z$ couplings are small. Generic diagrams for the above two processes are depicted in Fig. 1.

With values typically of the order of a few fb and below, the cross sections are small at $e^+ e^-$ linear colliders for masses of the Higgs boson in the intermediate mass range. High luminosities are therefore needed to produce a sufficiently large sample of Higgs-pair events and to isolate the signal from the background.

2. If light Higgs bosons with masses below about 130 GeV will be found, the Standard Model is likely embedded in a supersymmetric theory. The minimal supersymmetric extension of the Standard Model (MSSM) includes two iso-doublets of Higgs fields $\varphi_1$, $\varphi_2$ which, after three components are absorbed to provide masses to the electroweak gauge bosons, gives rise to a quintet of physical Higgs boson states: $h$, $H$, $A$, $H^\pm$ [13]. While a strong upper bound of about 130 GeV can be derived on the mass of the light CP-even neutral Higgs boson $h$ [14,15], the heavy CP-even and CP-odd neutral Higgs bosons $H$, $A$, and the charged Higgs bosons $H^\pm$ may have masses of the order of the electroweak symmetry scale $v$ up to about 1 TeV. This extended Higgs system can be described by two parameters at the tree level: one mass parameter which is generally identified with the pseudoscalar $A$ mass $M_A$, and $\tan \beta$, the ratio of the vacuum expectation values of the two neutral fields in the two iso-doublets.

The general self-interaction potential of two Higgs doublets $\varphi_i$ in a CP-conserving theory can be expressed by seven real couplings $\lambda_k$ and three real mass parameters $m_{11}^2$, $m_{22}^2$, and
when expressed in terms of the mass $M$ and the mass parameters by this approximation by $\alpha$

The charged and neutral CP-even Higgs boson masses, and the mixing angle $\tan 2\alpha$

mass parameters are parameterized by

$\lambda_1 = \lambda_2 = \frac{1}{4}(g^2 + g'^2)$
$\lambda_3 = \frac{1}{4}(g^2 - g'^2)$
$\lambda_4 = -\frac{1}{2}g^2$
$\lambda_5 = \lambda_6 = \lambda_7 = 0$

and the mass parameters by

$m_{t_2}^2 = \frac{1}{2}M_A^2 \sin 2\beta$
$m_{t_1}^2 = (M_A^2 + M_Z^2) \sin^2 \beta - \frac{1}{2}M_Z^2$
$m_{t_2}^2 = (M_A^2 + M_Z^2) \cos^2 \beta - \frac{1}{2}M_Z^2$

The mass $M_A$ and $\tan \beta$ determine the strength of the trilinear couplings of the physical Higgs bosons, together with the electroweak gauge couplings.

The mass parameters $m_{t_j}^2$ and the couplings $\lambda_i$ in the potential are affected by top and stop-loop radiative corrections. Radiative corrections in the one-loop leading $m_t^4$ approximation are parameterized by

$$\epsilon \approx \frac{3G_F m_t^4}{\sqrt{2} \pi^2 \sin^2 \beta} \log \frac{M_Z^2}{m_t^2}$$

where the scale of supersymmetry breaking is characterized by a common squark-mass value $M_S$, set 1 TeV in the numerical analyses; if stop mixing effects are modest on the SUSY scale, they can be accounted for by shifting $M_S^2$ in $\epsilon$ by the amount $\Delta M_S^2 = \bar{A}^2[1 - \bar{A}^2/(12M_S^2)]$. The charged and neutral CP-even Higgs boson masses, and the mixing angle $\alpha$ are given in this approximation by

$M_{hh}^2 = M_A^2 + M_Z^2 \cos^2 \theta_W$

$M_{h\mu}^2 = \frac{1}{2} \left[ M_A^2 + M_Z^2 + \epsilon \mp \sqrt{(M_A^2 + M_Z^2 + \epsilon)^2 - 4M_A^2M_Z^2 \cos 2\beta - 4\epsilon(M_A^2 \sin^2 \beta + M_Z^2 \cos^2 \beta)} \right]$

$\tan 2\alpha = \frac{\tan 2\beta - M_A^2 + M_Z^2}{M_A^2 - M_Z^2 + \epsilon/\cos 2\beta}$

with $-\frac{\pi}{2} \leq \alpha \leq 0$

when expressed in terms of the mass $M_A$ and $\tan \beta$.

The set of trilinear couplings between the neutral physical Higgs bosons can be written [14,17] in units of $\lambda_0$ as

$$\lambda_{hhh} = 3 \cos 2\alpha \sin(\beta + \alpha) + 3 \frac{\epsilon}{M_Z^2} \cos \alpha \frac{\cos \alpha}{\sin \beta} \cos^2 \alpha$$
\[ \lambda_{Hhh} = 2 \sin 2\alpha \sin(\beta + \alpha) - \cos 2\alpha \cos(\beta + \alpha) + 3 \frac{\epsilon \sin \alpha \cos^2 \alpha}{M_Z^2 \sin \beta} \]

\[ \lambda_{HHh} = -2 \sin 2\alpha \cos(\beta + \alpha) - \cos 2\alpha \sin(\beta + \alpha) + 3 \frac{\epsilon \cos \alpha \sin^2 \alpha}{M_Z^2 \sin \beta} \]

\[ \lambda_{HHH} = 3 \cos 2\alpha \cos(\beta + \alpha) + 3 \frac{\epsilon \sin \alpha \sin^2 \alpha}{M_Z^2 \sin \beta} \cos \beta \]

\[ \lambda_{hAA} = -\cos 2\beta \cos(\beta + \alpha) + \frac{\epsilon \sin \alpha \cos^2 \beta}{M_Z^2 \sin \beta} \]

(11)

In the decoupling limit \( M_A^2 \sim M_H^2 \sim M_{H^\pm} \gg v^2/2 \), the trilinear Higgs couplings reduce to

\[ \lambda_{Hhh} \rightarrow 3 M_h^2/M_Z^2 \]

\[ \lambda_{HHh} \rightarrow -3 \left( \frac{M_h^2}{M_Z^2} - \frac{\epsilon}{M_Z^2} \sin^2 \beta \right) \left( 1 - \frac{M_h^2}{M_Z^2} + \frac{\epsilon}{M_Z^2} \sin^2 \beta \right) - 3 \frac{\epsilon}{M_Z^2} \sin \beta \cos \beta \]

\[ \lambda_{HHH} \rightarrow 3 \left( \frac{M_h^2}{M_Z^2} - \frac{\epsilon}{M_Z^2} \sin^2 \beta \right) \left( 1 - \frac{M_h^2}{M_Z^2} + \frac{\epsilon}{M_Z^2} \sin^2 \beta \right) - 3 \frac{\epsilon \cos^3 \beta}{M_Z^2 \sin \beta} \]

\[ \lambda_{hAA} \rightarrow -\frac{M_h^2}{M_Z^2} + \frac{\epsilon}{M_Z^2} \]

\[ \lambda_{HAA} \rightarrow \sqrt{\left( \frac{M_h^2}{M_Z^2} - \frac{\epsilon}{M_Z^2} \sin^2 \beta \right) \left( 1 - \frac{M_h^2}{M_Z^2} + \frac{\epsilon}{M_Z^2} \sin^2 \beta \right) - \frac{\epsilon \cos^3 \beta}{M_Z^2 \sin \beta}} \]

(12)

with \( M_h^2 = M_Z^2 \cos^2 2\beta + \epsilon \sin^2 \beta \). As expected, the self-coupling of the light CP-even neutral Higgs boson \( h \) approaches the SM value in the decoupling limit.

In the subsequent numerical analysis the complete one-loop and the leading two-loop corrections to the MSSM Higgs masses and to the trilinear couplings are included, as presented in Ref. [15,16]. Mixing effects due to non-vanishing \( A, \mu \) parameters primarily affect the light Higgs mass; the upper limit on \( M_h \) depends strongly on the size of the mixing parameters, raising this value for \( \tan \beta \gtrsim 2.5 \) beyond the reach of LEP2, cf. Ref. [18]. The couplings however are affected less when evaluated for the physical Higgs masses. The variation of the trilinear couplings with \( M_A \) is shown for two values \( \tan \beta = 3 \) and 50 in Figs. 2 and 3. The region in which the couplings vary rapidly, corresponds to the \( h/H \) cross-over region of the two mass branches in the neutral CP-even sector, cf. eq. (10). The trilinear couplings between \( h, H \) and the pseudoscalar pair \( AA \) are in general significantly smaller than the trilinear couplings among the CP-even Higgs bosons. Small modifications of the couplings due to mixing effects are illustrated in Fig. 4 (for a detailed discussion of mixing effects see Ref. [19]).
Figure 2: Variation of the trilinear couplings between CP-even Higgs bosons with $M_A$ for $\tan\beta = 3$ and 50 in the MSSM; the region of rapid variations corresponds to the h/H crossover region in the neutral CP-even sector.
Figure 3: Upper set: Variation of the trilinear scalar couplings between CP-even and CP-odd Higgs bosons with $M_A$ for $\tan\beta = 3$ and 50 in the MSSM. Lower set: $ZZh$ and $ZZH$ gauge couplings in units of the SM coupling.
In contrast to the Standard Model, resonance production of the heavy neutral Higgs boson $H$ followed by subsequent decays $H \rightarrow hh$, plays a dominant role in part of the parameter space for moderate values of $\tan \beta$ and $H$ masses between 200 and 350 GeV, Ref. [20]. In this range, the branching ratio, derived from the partial width

$$\Gamma(H \rightarrow hh) = \frac{\sqrt{2}G_F M_\beta^2 \beta_H}{32\pi M_H^4} \lambda_{Hhh}^2$$

(13)

is neither too small nor too close to unity to be measured directly. [The decay of either $h$ or $H$ into a pair of pseudoscalar states, $h/H \rightarrow AA$, is kinematically not possible in the parameter range which the present analysis is based upon.] If double Higgs production is mediated by the resonant production of $H$, the total production cross section of light Higgs pairs increases by about an order of magnitude [17].

The trilinear Higgs-boson couplings are involved in a large number of processes at $e^+e^-$ linear colliders [17]:

- double Higgs-strahlung: $e^+e^- \rightarrow ZH_iH_j$ and $ZAA$ [$H_{i,j} = h, H$]
- triple Higgs production: $e^+e^- \rightarrow AH_iH_j$ and $AAA$
- $WW$ fusion: $e^+e^- \rightarrow \bar{\nu}_e\nu_eH_iH_j$ and $\bar{\nu}_e\nu_eAA$

The trilinear couplings which enter for various final states, cf. Fig. 5, are marked by a cross in the matrix Table 1. While the combination of couplings in Higgs-strahlung is isomorphic
Double Higgs-strahlung and associated triple Higgs-production are marked by a cross. The matrix for WW fusion is isomorphic to the matrix for Higgs-strahlung.

Table 1: The trilinear couplings between neutral CP-even and CP-odd MSSM Higgs bosons which can generically be probed in double Higgs-strahlung and associated triple Higgs-production, are marked by a cross. The matrix for WW fusion is isomorphic to the matrix for Higgs-strahlung.

In practice, not all the cross sections will be large enough to be accessible experimentally, preventing the straightforward solution for the complete set of couplings. In this situation however the reverse direction can be followed ["top-down approach"]. The trilinear Higgs couplings can stringently be tested by comparing the theoretical predictions of the cross sections with the experimental results for the accessible channels of double and triple Higgs production.

The processes $e^+e^- \rightarrow ZH_iA$ and $e^+e^- \rightarrow \bar{\nu}_e\nu_eH_iA$ [$H_i = h, H$] of mixed CP-even/CP-odd Higgs final states are generated through gauge interactions alone, mediated by virtual Z bosons decaying to the CP even–odd Higgs pair, $Z^* \rightarrow H_iA$. These parity-mixed processes do not involve trilinear Higgs-boson couplings.

3. In this paper we compare different mechanisms for the production of Higgs boson pairs in the Standard Model and in the minimal supersymmetric extension. An excerpt of the results, including comparisons with LHC channels, has been published in Ref. [21].
double Higgs-strahlung: \( e^+ e^- \rightarrow Z H_i H_j, Z A A [H_{i,j} = h, H] \)

triple Higgs production: \( e^+ e^- \rightarrow A H_i H_j, AAA \)

WW fusion: \( e^+ e^- \rightarrow \bar{\nu}_e \nu_e H_i H_j, AA \)

Figure 5: Processes contributing to double and triple Higgs production involving trilinear couplings in the MSSM.
relation to general 2-Higgs doublet models has recently been discussed in Ref. [22]. The
analyses have been carried out for $e^+e^-$ linear colliders [23], which are currently designed
[24] for a low-energy phase in the range $\sqrt{s} = 500$ GeV to 1 TeV, and a high-energy phase
above 1 TeV, potentially extending up to 5 TeV. The small cross sections require high
luminosities as foreseen in the TESLA design with targets of $\int \mathcal{L} = 300$ and 500 fb$^{-1}$ per
annum for $\sqrt{s} = 500$ and 800 GeV, respectively [25]. By analyzing the entire ensemble
of multi-Higgs final states as defined in Ref.[17], a theoretically coherent picture has been
developed for testing the trilinear self-couplings at high-energy colliders. Moreover, the fusion
processes are calculated exactly without reference to the equivalent-particle approximation.
Experimental simulations of signal and background processes depend strongly on detector
properties; they are beyond the scope of the present study which describes the first modest
theoretical steps into this area. Crude estimates for final states $e^+e^- \rightarrow Z(b\bar{b})(b\bar{b})$ [26] and $e^+e^- \rightarrow Z(WW)(WW)$ [27] can however be derived from the existing literature; dedicated
analyses of the reducible $Z(b\bar{b})(b\bar{b})$ background channel will be available in the near future
[28].

The paper is divided into two parts. In Section 2 we discuss the measurement of the
trilinear Higgs coupling in the Standard Model for double Higgs-strahlung and $WW$ fusion
at $e^+e^-$ linear colliders. In Section 3 this program, including the triple Higgs production, is
extended to the Minimal Supersymmetric Standard Model MSSM.

2. Higgs Pair–Production in the Standard Model

2.1 Double Higgs-strahlung

The (unpolarized) differential cross section for the process of double Higgs-strahlung $e^+e^- \rightarrow ZHH$, cf. Fig. 1, can be cast into the form [17]

$$
\frac{d\sigma(e^+e^- \rightarrow ZHH)}{dx_1 dx_2} = \frac{\sqrt{2} G_F^2 M_Z^2}{384 \pi^3 s} \left( v_e^2 + a_e^2 \right) \left( 1 - \mu_Z \right) Z
$$

(15)
after the angular dependence is integrated out. The vector and axial-vector $Z$ charges of
the electron are defined as usual, by $v_e = -1 + 4 \sin^2 \theta_W$ and $a_e = -1$. $x_{1,2} = 2E_{1,2}/\sqrt{s}$ are
the scaled energies of the two Higgs particles, $x_3 = 2 - x_1 - x_2$ is the scaled energy of the
$Z$ boson, and $y_i = 1 - x_i$; the square of the reduced masses is denoted by $\mu_i = M_i^2/s$, and
$\mu_{ij} = \mu_i - \mu_j$. In terms of these variables, the coefficient $Z$ may be written as:

$$
Z = a^2 f_0 + \frac{1}{4 \mu_Z (y_1 + \mu_HZ)} \left[ \frac{f_1}{y_1 + \mu_HZ} + \frac{f_2}{y_2 + \mu_HZ} + \frac{2\mu_Z a f_3}{y_1 \leftrightarrow y_2} \right] \left\{ y_1 \leftrightarrow y_2 \right\}
$$

(16)

with

$$
a = \frac{\lambda_{HHH}}{y_3 - \mu_HZ} + \frac{2}{y_1 + \mu_HZ} + \frac{2}{y_2 + \mu_HZ} + \frac{1}{\mu_Z}
$$

(17)
Figure 6a: The cross section for double Higgs-strahlung in the SM at three collider energies: 500 GeV, 1 TeV and 1.6 TeV. The electron/positron beams are taken oppositely polarized. The vertical arrows correspond to a variation of the trilinear Higgs coupling from 1/2 to 3/2 of the SM value.

The coefficients \( f_i \) are given by the following expressions,

\[
\begin{align*}
  f_0 &= \mu_Z[(y_1 + y_2)^2 + 8\mu_Z]/8 \\
  f_1 &= (y_1 - 1)^2(\mu_Z - y_1)^2 - 4\mu_H y_1(y_1 + y_1\mu_Z - 4\mu_Z) \\
  &\quad + \mu_Z(\mu_Z - 4\mu_H)(1 - 4\mu_H) - \mu_Z^2 \\
  f_2 &= [\mu_Z(y_3 + \mu_Z - 8\mu_H) - (1 + \mu_Z)y_1y_2(1 + y_3 + 2\mu_Z) \\
  &\quad + y_1y_2[y_1y_2 + 1 + \mu_Z^2 + 4\mu_H(1 + \mu_Z)] + 4\mu_H\mu_Z(1 + \mu_Z + 4\mu_H) + \mu_Z^2 \\
  f_3 &= y_1(1 - 1)(\mu_Z - y_1) - y_2(1 + y_1)(y_1 + \mu_Z) + 2\mu_Z(1 + \mu_Z - 4\mu_H)
\end{align*}
\]

The first term in the coefficient \( a \) includes the trilinear coupling \( \lambda_{HHH} \). The other terms are related to sequential Higgs-strahlung amplitudes and the 4-gauge-Higgs boson coupling; the individual terms can easily be identified by examining the characteristic propagators.

Since double Higgs-strahlung is mediated by s-channel Z-boson exchange, the cross section doubles if oppositely polarized electron and positron beams are used.

The cross sections for double Higgs-strahlung in the intermediate mass range are presented in Fig. 6a for total \( e^+e^- \) energies of \( \sqrt{s} = 500 \text{ GeV}, 1 \text{ TeV} \) and 1.6 TeV. The cross sections are shown for polarized electrons and positrons \( [\lambda_e - \lambda_{e^+} = -1] \); they reduce by a factor of 2 for unpolarized beams. As a result of the scaling behavior, the cross section for double Higgs-strahlung decreases with rising energy beyond the threshold region. The
Figure 6b: Variation of the cross section $\sigma(ZHH)$ with the modified trilinear coupling $\kappa \lambda_{HHH}$ at a collider energy of $\sqrt{s} = 500$ GeV and $M_H = 110$ GeV.

Figure 6c: The energy dependence of the cross section for double Higgs-strahlung for a fixed Higgs mass $M_H = 110$ GeV. The variation of the cross section for modified trilinear couplings $\kappa \lambda_{HHH}$ is indicated by the dashed lines.
cross section increases with rising trilinear self-coupling in the vicinity of the SM value. The sensitivity to the $HHH$ self-coupling is demonstrated in Fig. 6b for $\sqrt{s} = 500$ GeV and $M_H = 110$ GeV by varying the trilinear coupling $\kappa\lambda_{HHH}$ within the range $\kappa = -1$ and $+2$; the sensitivity is also illustrated by the vertical arrows in Fig. 6a for a variation $\kappa$ between $1/2$ and $3/2$. Evidently the cross section $\sigma(e^+e^- \rightarrow ZHH)$ is sensitive to the value of the trilinear coupling, which is not swamped by the irreducible background diagrams involving only the Higgs-gauge couplings. While the irreducible background diagrams become more important for rising energies, the sensitivity to the trilinear Higgs coupling is very large just above the kinematical threshold for the $ZHH$ final state as demonstrated in Fig. 6c. Near the threshold the propagator of the intermediate virtual Higgs boson connecting to the two real Higgs bosons through $\lambda_{HHH}$ in the final state is maximal. The maximum cross section for double Higgs-strahlung is reached at energies $\sqrt{s} \sim 2M_H + M_Z + 200$ GeV, i.e. for Higgs masses in the lower part of the intermediate range at $\sqrt{s} \sim 500$ GeV.

2.2 $WW$ Double-Higgs Fusion

The $WW$ fusion mechanism in $e^+e^- \rightarrow \bar{\nu}_\nu HH$, cf. Fig. 1, provides the largest cross section for Higgs bosons pairs in the intermediate mass range at high $e^+e^-$ collider energies, in particular for polarized beams.

The fusion cross section can roughly be estimated in the equivalent $W$-boson approximation. The production amplitude for the dominant longitudinal degrees of freedom is given [29] by

$$M_{LL} = \frac{G_F^2 M_W^4}{4\pi s} \frac{\beta_H}{(1 - \beta_W^2)} \left( 1 + \frac{\lambda_{HHH}}{(s - M_H^2)/M_Z^2} \right) \left( 1 + \frac{1}{s} \right) \left( \frac{1}{s} \right)^2$$

with $\beta_{W,H}$ denoting the $W$, $H$ velocities in the c.m. frame, and $x_W = (1 - 2M_H^2/s)/(\beta_W \beta_H)$.

$s^{1/2}$ is the invariant energy of the $WW$ pair; $\theta$ is the Higgs production angle in the c.m. frame of $WW$. Integrating out the angular dependence, the corresponding total cross section can be derived [17] as

$$\hat{\sigma}_{LL} = \frac{G_F^2 M_W^4}{4\pi s} \frac{\beta_H}{(1 - \beta_W^2)} \left( 1 + \frac{\lambda_{HHH}}{(s - M_H^2)/M_Z^2} \right)^2$$

$$+ \frac{16}{(1 + \beta_W^2 - 4\beta_H^2/\beta_W^2)} \left[ \beta_H^2 (-\beta_H x_W^2 + 4\beta_W^2 x_W - 4\beta_W^2) + (1 + \beta_H^2 - \beta_W^4) \right]$$

$$+ \frac{1}{\beta_W^2 \beta_H} \left( l_W + \frac{2x_W}{x_W - 1} \right) \left[ \beta_H (\beta_H x_W - 4\beta_W) (1 + \beta_W^2 - \beta_W^4 + 3x_W^2 \beta_H^2) \right]$$

$$+ \beta_H^2 x_W (1 - \beta_W^4 + 13\beta_W^2) - \frac{1}{x_W} (1 + \beta_W^2 - \beta_W^4)^2$$

$$+ \frac{2(1 + \beta_W^4)}{\beta_W \beta_H} \left[ 1 + \frac{\lambda_{HHH}}{(s - M_H^2)/M_Z^2} \right] \left[ l_W (1 + \beta_W^2 - \beta_W^4 - 2\beta_W \beta_H x_W + \beta_H^2 x_W) \right]$$

13
Table 2: Total cross sections for SM pair production in WW and ZZ fusion at $e^+e^-$ colliders for two characteristic energies and masses in the intermediate range (unpolarized beams).

$$+2\beta_H(x_W\beta_H - 2\beta_W)\right]$$

(20)

with $l_W = \log([x_W - 1]/[x_W + 1])$. After folding the cross section of the subprocess with the longitudinal $W_L$ spectra [30],

$$f_L(z) = \frac{G_F M_W^2}{2\sqrt{2}\pi^2} \frac{1 - z}{z} \quad [z = E_W/E_e]$$

(21)

a rough estimate of the total $e^+e^-$ cross section can be obtained; it exceeds the exact value by about a factor 2 to 5 depending on the collider energy and the Higgs mass. The estimate is useful nevertheless for a transparent interpretation of the exact results.

For large WW energies the process $WW \rightarrow HH$ is dominated by t-channel $W$ exchange which is independent of the trilinear Higgs coupling. However, even at high c.m. energies the convoluted process $e^+e^- \rightarrow \bar{\nu}_e\nu_eHH$ receives most of the contributions from the lower end of the $WW$ energy spectrum so that the sensitivity on $\lambda_{HHH}$ is preserved also in this domain.

The exact cross sections for off-shell $W$ bosons, transverse degrees of freedom included, have been calculated numerically, based on the semi-analytical CompHEP program [31]. Electron and positron beams are assumed to be polarized, giving rise to a cross section four times larger than for unpolarized beams. The results are shown in Fig. 7a for the three energies discussed before: $\sqrt{s} = 500$ GeV, 1 TeV and 1.6 TeV. As expected, the fusion cross sections increase with rising energy. Again, the variation of the cross section with $\kappa\lambda_{HHH}$, $\kappa = -1$ to +2, is demonstrated in Fig. 7b for $\sqrt{s} = 1$ TeV and $M_H = 110$ GeV, and by the vertical arrows for $\kappa = 1/2$ to 3/2 in Fig. 7a. Due to the destructive interference with the gauge part of the amplitude, the cross sections drop with rising $\lambda_{HHH}$. The ZZ fusion
cross section is an order of magnitude smaller than the WW fusion cross section since the Z couplings of the electron/positron are small, cf. Table 2.

It is apparent from the preceding discussion that double Higgs-strahlung $e^+e^- \rightarrow ZHH$ at moderate energies and WW fusion at TeV energies are the preferred channels for measurements of the trilinear self-coupling $\lambda_{HHH}$ of the SM Higgs boson. Electron and positron beam polarization enhance the cross sections by factors 2 and 4 for Higgs-strahlung and WW fusion, respectively. Since the cross sections are small, high luminosity of the $e^+e^-$ linear collider is essential for performing these fundamental experiments. Even though the rates of order $10^3$ to $3 \cdot 10^3$ events for an integrated luminosity of 2 ab$^{-1}$ as foreseen for TESLA, are moderate, clear multi-$b$ signatures like $e^+e^- \rightarrow Z(b\bar{b})(b\bar{b})$ and $e^+e^- \rightarrow (b\bar{b})(b\bar{b}) + \not{E}$ will help to isolate the signal from the background.

The complete reconstruction of the Higgs potential in the Standard Model requires the measurement of the quadrilinear coupling $\lambda_{HHHH}$, too. This coupling is suppressed relative to the trilinear coupling effectively by a factor of the order of the weak gauge coupling for masses in the lower part of the intermediate Higgs mass range. The quadrilinear coupling can be accessed directly only through the production of three Higgs bosons: $e^+e^- \rightarrow ZHHH$ and $e^+e^- \rightarrow \tilde{\nu}_e\nu_eHHH$. However, these cross sections are reduced by three orders of magnitude compared to the corresponding double-Higgs channels. As argued before, the signal amplitude involving the four-Higgs coupling [as well as the irreducible Higgs-strahlung amplitudes] is suppressed, leading to a reduction of the signal cross section by a factor
Figure 7b: Variation of the cross section \( \sigma(e^+ e^- \rightarrow \bar{\nu}_{\nu} HH) \) with the modified trilinear coupling \( \kappa \lambda_{HH} \) at a collider energy of \( \sqrt{s} = 1 \) TeV and \( M_H = 110 \) GeV.

\( [\lambda_{HHH}^2 \lambda_0^4 / 16\pi^2] / [\lambda_{HHH}^2 \lambda_0^2 / M_Z^2] \approx 10^{-3} \). Irreducible background diagrams are similarly suppressed. Moreover, the phase space is reduced by the additional heavy particle in the final state. A few illustrative examples for triple Higgs-strahlung are listed in Table 3.

### 3. The Supersymmetric Higgs Sector

A large ensemble of Higgs couplings are present in supersymmetric theories. Even in the minimal realization MSSM, six different trilinear couplings \( hhh, Hhh, HHh, HHH, hAA, HAA \) are generated among the neutral particles, and many more quadrilinear couplings [22]. Since in major parts of the MSSM parameter space the Higgs bosons \( H, A, H^\pm \) are quite heavy, we will focus primarily on the production of light neutral pairs \( hh \), yet the production of heavy Higgs bosons will also be discussed where appropriate. The channels in which trilinear Higgs couplings can be probed in \( e^+ e^- \) collisions, have been cataloged in Table 1.

Barring the exceptional case of very light pseudoscalar \( A \) states, \( \lambda_{Hhh} \) is the only trilinear coupling that may be measured in resonance decays, \( H \rightarrow hh \), while all the other couplings must be accessed in continuum pair production. The relevant mechanisms have been categorized in Fig. 5 for double Higgs-strahlung, associated triple Higgs production and \( WW \) double-Higgs fusion.
Table 3: Representative values for triple SM Higgs-strahlung (unpolarized beams). The sensitivity to the quadrilinear coupling is illustrated by the variation of the cross sections when $\lambda_{HHHH}$ is altered by factors $1/2$ and $3/2$, as indicated in the square brackets.

3.1 Double Higgs-strahlung

The (unpolarized) cross section for double Higgs-strahlung, $e^+e^- \rightarrow Zhh$, is modified [17] (see also [19]) with regard to the Standard Model by $H, A$ exchange diagrams, cf. Fig. 5:

$$\frac{d\sigma(e^+e^- \rightarrow Zhh)}{dx_1dx_2} = \frac{\sqrt{2}G_F^3M_Z^6v_e^2 + a_e^2}{384\pi^4s} \frac{1}{(1-\mu Z)^2} Z_{11}$$

with

$$Z_{11} = a^2 f_0 + \frac{a}{2} \left[ \frac{\sin^2(\beta - \alpha)f_3}{y_1 + \mu_1Z} + \frac{\cos^2(\beta - \alpha)f_3}{y_1 + \mu_1A} \right] + \frac{\sin^4(\beta - \alpha)}{4\mu_Z(y_1 + \mu_1Z)} \left[ \frac{f_1}{y_1 + \mu_1Z} + \frac{f_2}{y_2 + \mu_1Z} \right] + \frac{\cos^4(\beta - \alpha)}{4\mu_Z(y_1 + \mu_1A)} \left[ \frac{f_1}{y_1 + \mu_1A} + \frac{f_2}{y_2 + \mu_1A} \right] + \frac{\sin^2(2\beta - \alpha)}{8\mu_Z(y_1 + \mu_1A)} \left[ \frac{f_1}{y_1 + \mu_1Z} + \frac{f_2}{y_2 + \mu_1Z} \right] + \{ y_1 \leftrightarrow y_2 \}$$

and

$$a = \left[ \frac{\lambda_{hhh} \sin(\beta - \alpha)}{y_3 - \mu_1Z} + \frac{\lambda_{Hhh} \cos(\beta - \alpha)}{y_3 - \mu_2Z} \right] + \frac{2\sin^2(\beta - \alpha)}{y_1 + \mu_1Z} + \frac{2\sin^2(\beta - \alpha)}{y_2 + \mu_1Z} + \frac{1}{\mu_Z}$$

[The notation follows the Standard Model, with $\mu_1 = M_H^2/s$ and $\mu_2 = M_H^2/s$.] In parameter ranges in which the heavy neutral Higgs boson $H$ or the pseudoscalar Higgs boson $A$ becomes resonant, the decay widths are implicitly included by shifting the masses to complex values $M \rightarrow M - i\Gamma/2$, i.e. $\mu_i \rightarrow \mu_i - i\gamma_i$ with the reduced width $\gamma_i = M_i\Gamma_i/s$, and by changing
Figure 8: Total cross sections for MSSM hh production via double Higgs-strahlung at $e^+e^-$
linear colliders for $\tan\beta = 3, 50$ and $\sqrt{s} = 500$ GeV, including mixing effects ($A = 1$ TeV,
$\mu = -1/1$ TeV for $\tan\beta = 3/50$). The dotted line indicates the SM cross section.

The total cross sections are shown in Fig. 8 for the $e^+e^-$ collider energy $\sqrt{s} = 500$ GeV.
The parameter $\tan\beta$ is chosen to be 3 and 50 and the mixing parameters $A = 1$ TeV and
$\mu = -1/1$ TeV and 1 TeV, respectively. If $\tan\beta$ and the mass $M_h$ are fixed, the masses of the
other heavy Higgs bosons are predicted in the MSSM [20]. Since the vertices are suppressed
by $\sin \beta / \cos \alpha$ functions of the mixing angles $\beta$ and $\alpha$, the continuum $hh$ cross sections are
suppressed compared to the Standard Model. The size of the cross sections increases for
moderate $\tan\beta$ by nearly an order of magnitude if the $hh$ final state can be generated in
the chain $e^+e^- \rightarrow ZH \rightarrow Zhh$ via resonant $H$ Higgs-strahlung. If the light Higgs mass
approaches the upper limit for a given value of $\tan\beta$, the decoupling theorem drives the
cross section of the supersymmetric Higgs boson back to its Standard Model value since the
Higgs particles $A, H, H^\pm$ become asymptotically heavy in this limit. As a result of the
decoupling theorem, resonance production is not effective for large $\tan\beta$. If the $H$ mass is
large enough to allow decays to $hh$ pairs, the $ZZH$ coupling is already too small to generate
a sizable cross section.

The cross sections for other $ZH_iH_j \ [H_{i,j} = h, H]$ final states are presented in the Appendix.
While the basic structure remains the same, the complexity increases due to unequal
masses of the final-state particles. The reduction of the $Zhh$ cross section is partly compen-
sated by the $ZHh$ and $ZHH$ cross sections so that their sum adds up approximately to
the SM value, as demonstrated in Fig. 9a for $\tan\beta = 3$ at $\sqrt{s} = 500$ GeV and $hh$, $Hh$ and $HH$ final states. Evidently, if kinematically possible, the MSSM cross sections add up to approximately the SM cross section.

3.2 Triple-Higgs Production

The 2-particle processes $e^+e^- \rightarrow ZH_i$ and $e^+e^- \rightarrow AH_i$ are among themselves and mutually complementary to each other in the MSSM [32], coming with the coefficients $\sin^2(\beta - \alpha)/\cos^2(\beta - \alpha)$ and $\cos^2(\beta - \alpha)/\sin^2(\beta - \alpha)$ for $H_i = h, H$, respectively. Since multi-Higgs final states are mediated by virtual $h, H$ bosons, the two types of self-complementarity and mutual complementarity are also operative in double-Higgs production: $e^+e^- \rightarrow ZH_iH_j$, $ZAA$ and $AH_iH_j, AAA$. As the different mechanisms are intertwined, the complementarity between these 3-particle final states is of more complex matrix form, as evident from Fig. 5.

We will analyze in this section the processes involving only the light neutral Higgs boson $h$, $e^+e^- \rightarrow Ahh$, and three pseudoscalar Higgs bosons $A$, $e^+e^- \rightarrow AAA$. The more cumbersome expressions for heavy neutral Higgs bosons $H$ are deferred to the Appendix.

In the first case one finds for the unpolarized cross section

$$\frac{d\sigma[e^+e^- \rightarrow Ahh]}{dx_1dx_2} = \frac{G_F^2M^5_Z}{768\sqrt{2}\pi s} \frac{v^2_e + a^2_e}{(1 - \mu_Z)^2} A_{111}$$

(25)
The coefficients $g$:

$$A_{11} = \left[ \frac{c_1 \lambda_{hhh}}{y_3 - \mu_{1A}} + \frac{c_2 \lambda_{Hhh}}{y_3 - \mu_{2A}} \right] \frac{g_0}{2} + \frac{c_1^2 \lambda_{hAA}^2}{(y_1 + \mu_{1A})^2} g_1 + \frac{c_1^2 d_1^2}{(y_1 + \mu_{1A})^2} g_2$$

$$+ \left[ \frac{c_1 \lambda_{hhh}}{y_3 - \mu_{1A}} + \frac{c_2 \lambda_{Hhh}}{y_3 - \mu_{2A}} \right] \frac{g_3}{2(y_1 + \mu_{1A}) (y_2 + \mu_{1A})} g_5 + \frac{c_1^2 d_1^2}{(y_1 + \mu_{1A}) (y_2 + \mu_{1A})} g_7$$

$$+ \left\{ y_1 \leftrightarrow y_2 \right\}$$

with $\mu_{1,2} = M_{h,H}^2/s$ and the vertex coefficients

$$\frac{c_1}{c_2} = \cos(\beta - \alpha)/ - \sin(\beta - \alpha) \quad \text{and} \quad \frac{d_1}{d_2} = \sin(\beta - \alpha)/ \cos(\beta - \alpha)$$

The coefficients $g_k$ are given by

$$g_0 = \mu_Z [(y_1 + y_2)^2 - 4 \mu_A]$$
$$g_1 = \mu_Z [y_1^2 - 2 y_1 - 4 \mu_1 + 1]$$
$$g_2 = 2 \mu_Z [y_1 (y_1 + 2) + 4 y_2 (y_2 + y_1 - 1) + 1 - 4 (\mu_1 + 2 \mu_A)] + (\mu_1 - \mu_A)^2$$
$$+ 8 + (1 - y_1)^2 - 4 \mu_1 \mu_Z + (\mu_1 - \mu_A)^2 [4 y_2 (1 + y_1) + 2 (y_1^2 - 1)]$$
$$g_3 = 2 \mu_Z (y_1^2 - y_1 + y_2 + y_1 y_2 - 2 \mu_A)$$
$$g_4 = 2 \mu_Z (y_1^2 + y_1 + 2 y_2 - y_2 + 3 y_1 y_2 - 6 \mu_A)$$
$$+ 2 (\mu_1 - \mu_A) (y_1^2 - y_1 + y_2 + y_1 y_2 - 2 \mu_A)$$
$$g_5 = 2 \mu_Z (y_1 + y_2 + y_1 y_2 + 4 \mu_1 - 2 \mu_A - 1)$$
$$g_6 = 2 \mu_Z (y_1^2 + 2 y_1 y_2 + 2 y_2 + 4 \mu_1 - 4 \mu_A - 1)$$
$$+ 2 (\mu_1 - \mu_A) (y_1^2 - 2 y_1 - 4 \mu_1 + 1)$$
$$g_7 = 2 \mu_Z (2 y_1^2 - 3 y_1 + y_1 y_2 + y_2 - 4 \mu_1 - 2 \mu_A + 1)$$
$$+ (\mu_1 - \mu_A) (y_1 + y_1 y_2 + y_2 + 4 \mu_1 - 2 \mu_A - 1)$$
$$g_8 = 2 \mu_Z (y_1 + y_2 + 2 y_1^2 + 2 y_2^2 + 5 y_1 y_2 - 1 + 4 \mu_1 - 10 \mu_A)$$
$$+ 4 (\mu_1 - \mu_A) (-2 \mu_1 - \mu_A - y_1 - y_2 + 1)$$
$$+ 2 (\mu_1 - \mu_A) ((y_1 + y_2 + y_1 y_2 + y_1^2 + y_2^2 - 1) \mu_Z + 2 y_1^2 + 4 \mu_A - \mu_1 + \mu_A)$$
$$+ 6 \mu_A (\mu_A^2 - \mu_1^2) ((1 + y_1)(1 + y_2))/\mu_Z$$

The notation of the kinematics is the same as for Higgs-strahlung.

Since only a few diagrams contribute to triple $A$ production, cf. Fig. 5, the expression
for this cross section is exceptionally simple:

$$\frac{d\sigma[e^+e^- \rightarrow AAA]}{dx_1dx_2} = \frac{G_F^2 M_Z^6 v_e^2 + a_e^2}{768\sqrt{2}\pi^3 s (1 - \mu_Z)^2} \mathcal{A}_{33}$$

(29)

where

$$\mathcal{A}_{33} = D_3^2 g_0 + D_1^2 g_1 + D_2^2 g_1' - D_3 D_1 g_3 - D_3 D_2 g_5' + D_1 D_2 g_5$$

(30)

and

$$D_k = \frac{\lambda_{hAAc_1}}{y_k - \mu_{1A}} + \frac{\lambda_{HAAc_2}}{y_k - \mu_{2A}}$$

(31)

The scaled mass parameter $\mu_1$ must be replaced by $\mu_A$ in the coefficients $g_i$ and $g'_i$ defined earlier.

The size of the total cross section $\sigma(e^+e^- \rightarrow Ahh)$ and $\sigma(e^+e^- \rightarrow AAA)$ is compared with double Higgs-strahlung $\sigma(e^+e^- \rightarrow Zhh)$ in Fig. 9b for $\tan\beta = 3$ at $\sqrt{s} = 1$ TeV. Both these cross sections involving pseudoscalar Higgs bosons are small in the continuum. The effective coupling in the chain $Ah_{\text{virt}} \rightarrow Ahh$ is $\cos(\beta - \alpha)\lambda_{hhh}$ while in the chain $AH_{\text{virt}} \rightarrow Ahh$ it is $\sin(\beta - \alpha)\lambda_{Hhh}$; both products are small either in the first or second coefficient. Only for resonance $H$ decays $AH \rightarrow Ahh$ the cross section becomes very large. A similar picture evolves for the triple $A$ final state. The chain $Ah_{\text{virt}} \rightarrow AAA$ is proportional to the coefficient $\cos(\beta - \alpha)\lambda_{hAA}$ in which one of the terms is always small. The chain $AH_{\text{virt}} \rightarrow AAA$, on
the other hand, is proportional to \( \sin(\beta - \alpha) \lambda_{HAA} \); for this coefficient the trilinear coupling \( \lambda_{HAA} \) is only of order 1/2 so that, together with phase space suppression, the cross section remains small in the entire parameter space.

### 3.3 WW Double-Higgs Fusion

The WW fusion mechanism for the production of supersymmetric Higgs pairs can be treated in the same way. The dominant longitudinal amplitude for on-shell W bosons involves \( A, H \) and \( H^\pm \) exchange diagrams in addition to the SM-type contributions:

\[
\mathcal{M}_{LL} = \frac{G_F s}{\sqrt{2}} \left\{ (1 + \beta_W^2) \left[ 1 + \frac{\lambda_{Hhh} \sin(\beta - \alpha)}{(s - M_W^2)/M_Z^2} + \frac{\lambda_{Hhh} \cos(\beta - \alpha)}{(s - M_H^2)/M_Z^2} \right] + \frac{\sin^2(\beta - \alpha)}{\beta_W \beta_h} \left[ (1 - \beta_W^2) + (\beta_W - \beta_h \cos \theta)^2 \right] - \frac{(1 - \beta_W^2)}{\cos \theta + x_W} - \frac{(1 - \beta_W^2)}{\cos \theta + x_W} \left[ (\beta_W - \beta_h \cos \theta)^2 \right] - \frac{(\beta_W + \beta_h \cos \theta)^2}{\cos \theta + x_+} \right\} \tag{32}
\]

As before, \( s^{1/2} \) is the c.m. energy of the subprocess, \( \theta \) the scattering angle, \( \beta_W \) and \( \beta_h \) are the velocities of the \( W \) and \( h \) bosons, and

\[
x_W = \frac{1 - 2\mu_h}{\beta_W \beta_h} \quad \text{and} \quad x_+ = \frac{1 - 2\mu_h + 2\mu_{H^\pm} - 2\mu_W}{\beta_W \beta_h} \tag{33}
\]

After integrating out the angular dependence, the total cross section of the fusion subprocess is given by the expression

\[
\hat{\sigma}_{LL} = \frac{G_F^2 M_W^4}{16 \pi s} \frac{\beta_h}{\beta_W (1 - \beta_W^2)} \left\{ (1 + \beta_W^2)^2 \left[ \frac{\lambda_{Hhh} d_1}{(s - M_H^2)/M_Z^2} + \frac{\lambda_{Hhh} d_2}{(s - M_H^2)/M_Z^2} + 1 \right]^2 + \frac{2(1 + \beta_W^2)}{\beta_W \beta_h} \left[ \frac{\lambda_{Hhh} d_1}{(s - M_H^2)/M_Z^2} + \frac{\lambda_{Hhh} d_2}{(s - M_H^2)/M_Z^2} + 1 \right] \left[ d_1^W a_1^W + c_1^W a_1^W \right] + \left( \frac{d_1^W}{\beta_W \beta_h} \right)^2 a_2^W \left( \frac{c_1^W}{\beta_W \beta_h} \right) a_2^W + 4 \left( \frac{c_1^W d_1^W}{\beta_W \beta_h} \right) [a_3^W + a_3^W \right}\} \tag{34}
\]

with

\[
a_1^W = \left[ (x_W \beta_h - \beta_W)^2 + r_W \right] t_W + 2\beta_h (x_W \beta_h - 2\beta_W) \frac{1}{x_W^2 - 1} \left[ x_W^2 \beta_h^2 (3\beta_h x_W^2 + 2r_W + 14\beta_W^2) \right. \\
- \left. (\beta_W^2 + r_W)^2 - 4\beta_h \beta_W x_W (3\beta_h^2 x_W^2 + \beta_W^2 + r_W) \right] - \frac{4}{x_W^2 - 1} \left[ \beta_h^2 (\beta_W^2 x_W^2 + 4\beta_W^2 - 4\beta_h x_W \beta_W) - (\beta_W^2 + r_W)^2 \right]
\]
Figure 10a: Total cross sections for MSSM $hh$ production via double $WW$ double-Higgs fusion at $e^+ e^-$ linear colliders for $\tan \beta = 3, 50$ and $\sqrt{s} = 1.6$ TeV, including mixing effects ($\mathcal{A} = 1$ TeV, $\mu = -1/1$ TeV for $\tan \beta = 3/50$).

\[
\begin{align*}
\sigma_{\text{pol}}^{[\text{fb}]}/\sqrt{s} & = \frac{1}{x_+^2 - x_W^2} t_W \left[ 2\beta_W \beta_h x_W \left( \beta_W^2 + x_W^2 \beta_h^2 \right) (x_W + x_+) + x_W r_W + x_+ r_+ \right] \\
& - x_+(r_+ + r_W + \beta_h^2 x_W^2) (\beta_W^2 + \beta_h^2 x_W^2 - \beta_W^2 (x_+ \beta_W^2 + 4 \beta_h^2 x_W^2 + x_+ x_W^2 \beta_h^2) \\
& - x_+ r_W r_+ \right] + \beta_h^2 \left[ \beta_h^2 x_W - 2 \beta_W \beta_h (x_W + x_+) + 4 \beta_W^2 \right] \\
a_i^+ & \equiv a_i^W \ (x_W \leftrightarrow x_+, \ r_W \leftrightarrow r_+) \\
\end{align*}
\]

and $r_W = 1 - \beta_W^4$, $r_+ = 0$.

The final cross sections have been calculated for off-shell $W$'s and transverse polarizations included, i.e. without relying on the $LL$ and the equivalent $W$-boson approximation. The $e^+ e^-$ beams are assumed to be polarized. For modest $\tan \beta$, the $hh$ continuum production is slightly suppressed by the mixing coefficients with regard to the Standard Model, Fig. 10a. The cross section is strongly enhanced in the parameter range where the fusion subprocess is resonant, $WW \rightarrow H \rightarrow hh$. For large $\tan \beta$ the $WW$ fusion cross section is strongly suppressed by one to two orders of magnitude and resonance decay is not possible anymore. This is a consequence of the small gauge couplings in this parameter range which are drastically reduced by the mixing coefficients. Since the second CP-even Higgs boson $H$ is fairly light for these parameters, the small $hh$ continuum production is complemented by $Hh$ and $HH$ production channels, as evident from Fig. 10b. The cross sections for the production of $Hh$, $HH$ and $AA$ pairs are cataloged in the Appendix.
$e^+e^- \rightarrow \bar{\nu}\nu H_i H_j; \sqrt{s} = 1.6$ TeV

Figure 10b: Total cross sections for WW double-Higgs fusion with hh, Hh and HH final states for $\sqrt{s} = 1.6$ TeV and $\tan \beta = 50$, including mixing effects ($A = 1$ TeV, $\mu = 1$ TeV).

3.4 Sensitivity Areas

The results obtained in the preceding sections can be summarized in compact form by constructing sensitivity areas for the trilinear SUSY Higgs couplings based on the cross sections for double Higgs-strahlung and triple Higgs production. WW double-Higgs fusion can provide additional information on the Higgs self-couplings.

The sensitivity areas will be defined in the $[M_A, \tan \beta]$ plane [17]. The criteria for accepting a point in the plane as accessible for the measurement of a specific trilinear coupling are set as follows:

(i) $\sigma[\lambda] > 0.01 \text{ fb}$

(ii) $\text{var}\{\lambda \rightarrow (1 \pm \frac{1}{2})\lambda\} > 2 \text{ st.dev.}\{\lambda\}$ for $\int \mathcal{L} = 2 \text{ ab}^{-1}$

The first criterion demands at least 20 events in a sample collected for an integrated luminosity of $2 \text{ ab}^{-1}$, corresponding to about the lifetime of a high-luminosity machine such as TESLA. The second criterion demands a 50% change of the signal parameter to exceed a statistical fluctuation of 2 standard deviations. Even though the two criteria may look quite loose, tightening (i) and/or (ii) does not have a large impact on the size of the sensitivity areas in the $[M_A, \tan \beta]$ plane, see Ref. [19]. For the sake of simplicity, the $e^+e^-$ beams are assumed to be unpolarized and mixing effects are neglected.

Sensitivity areas of the trilinear couplings for the set of processes defined in the correlation matrix Table 1, are depicted in Figs. 11 – 13. If at most one heavy Higgs boson is present in the final states, the lower energy $\sqrt{s} = 500$ GeV is most preferable in the case of double Higgs-strahlung. $HH$ final states in double Higgs-strahlung and triple Higgs production involving $A$ give rise to larger sensitivity areas at the high energy $\sqrt{s} = 1$ TeV; increasing
the energy to 1.6 TeV does not improve on the signal as a result of the scaling behavior of the Higgs-strahlung cross section. Apart from small regions in which interference effects play a role, the magnitude of the sensitivity regions in the parameter $\tan\beta$ is readily explained by the magnitude of the parameters $\lambda \sin(\beta - \alpha)$ and $\lambda \cos(\beta - \alpha)$, shown individually in Figs. 2 and 3. For large $M_A$ the sensitivity criteria cannot be met any more either as a result of phase space effects or due to the suppression of the $H$, $A$, $H^\pm$ propagators for large masses. While the trilinear coupling of the light neutral CP-even Higgs boson is accessible in nearly the entire MSSM parameter space, the regions for $\lambda$’s involving heavy Higgs bosons are rather restricted.

Since neither experimental efficiencies nor background related cuts are considered in this paper, the areas shown in Figs. 11, 12 and 13 must be interpreted as maximal envelopes. They are expected to shrink when experimental efficiencies are properly taken into account; more elaborate cuts on signal and backgrounds, however, may help reduce their impact.

4. Conclusions

In the present paper we have analyzed the production of Higgs boson pairs and triple Higgs final states at $e^+e^-$ linear colliders. They will allow us to measure fundamental trilinear Higgs self-couplings. The first theoretical steps into this area have been taken by calculating the production cross sections in the Standard Model for Higgs bosons in the intermediate mass range and for Higgs bosons in the minimal supersymmetric extension. Earlier results have been combined with new calculations in this analysis.

The cross sections in the Standard Model for double Higgs-strahlung, triple Higgs production and double-Higgs fusion are small so that high luminosities are needed to perform these experiments. Even though the $e^+e^-$ cross sections are below the hadronic cross sections, the strongly reduced number of background events renders the search for the Higgs-pair signal events, through $bbbb$ final states for instance, easier in the $e^+e^-$ environment than in jetty LHC final states. For sufficiently high luminosities even the first phase of these colliders with an energy of 500 GeV will allow the experimental analysis of self-couplings for Higgs bosons in the intermediate mass range.

The extended Higgs spectrum in supersymmetric theories gives rise to a plethora of trilinear and quadrilinear couplings. The $hhh$ coupling is generally quite different from the Standard Model. It can be measured in $hh$ continuum production at $e^+e^-$ linear colliders. Other couplings between heavy and light MSSM Higgs bosons can be measured as well, though only in restricted areas of the [$M_A$, $\tan\beta$] parameter space as illustrated in the set of Figs. 11 – 13.
Figure 11: Sensitivity to $\lambda_{hhh}$ and $\lambda_{Hhh}$ in the processes $e^+e^- \rightarrow Zhh$ and $e^+e^- \rightarrow Ahh$ for collider energies 500 GeV and 1 TeV, respectively (no mixing). [Vanishing trilinear couplings are indicated by contour lines.]
Figure 12: Sensitivity to $\lambda_{Hhh}$, $\lambda_{HHh}$ and $\lambda_{HHH}$ in the processes $e^+e^-\rightarrow ZHh$ and $e^+e^-\rightarrow ZHH$ for collider energies 500 GeV and 1 TeV, respectively (no mixing).
Figure 13: Sensitivity to $\lambda_{hAA}$ and $\lambda_{HAA}$ in the process $e^+e^-\rightarrow ZAA$ for a collider energy of 1 TeV (no mixing).

Lutz, L. Maiani, P. Osland, P. Pandita F. Richard and R. Settles. Special thanks go to M. Spira for providing us with a program for 2-loop SUSY couplings, and for the careful reading of the manuscript.
Appendix A: Double Higgs-strahlung Processes

In this appendix, we present the cross sections for the pair production of the heavy MSSM Higgs bosons in the Higgs-strahlung processes, \( e^+e^- \rightarrow ZH_I H_J \) and \( ZAA \) with \( H_{i,j} = h, H \). The mixed process \( e^+e^- \rightarrow ZH_I A \) is generated at the tree level by gauge couplings only. The notation is the same as in Section 2.1. The trilinear couplings have been introduced earlier. Modifications of the SM Higgs-gauge coupling in the MSSM are accounted for by the mixing parameters:

\[
\begin{align*}
  VVh: & \quad d_1 = \sin(\beta - \alpha) \quad VVH: & \quad d_2 = \cos(\beta - \alpha) \quad VVA: & \quad d_3 = 0 \\
  VAh: & \quad c_1 = \cos(\beta - \alpha) \quad VAH: & \quad c_2 = -\sin(\beta - \alpha) \quad WAH: & \quad c_3 = 1
\end{align*}
\]

(A.1)

for \( V = Z \) and \( W \). The Higgs bosons are neutral except in the last entry.

A1: \( e^+e^- \rightarrow ZH_I H_J \)

The double differential cross section of the process \( e^+e^- \rightarrow ZH_I H_J \) is given for unpolarized beams by the expression

\[
\frac{d\sigma[e^+e^- \rightarrow ZH_I H_J]}{dx_1 dx_2} = \frac{\sqrt{2} G_F^4 M_Z^6}{384 \pi^3 s} \frac{v_\tau^2 + a_\tau^2}{(1 - \mu_Z)^2} Z_{ij}
\]

(A.2)

In terms of the variables \( y_1, y_2, y_3 \) defined in Section 2.1, and with \( \mu_i = M_{R_i}/s, \mu_{ij} = \mu_i - \mu_j \), etc., the coefficient \( Z_{ij} \) in the cross sections can be written as

\[
Z_{ij} = a_{ij}^2 f_0 + a_{ij} \left[ \frac{d_1 d_j f_3}{y_1 + \mu_i Z} + \frac{c_1 c_j f_3}{y_1 + \mu_i A} \right] + \frac{(d_1 d_j)^2}{4 \mu_Z (y_1 + \mu_i Z)} \left[ \frac{f_1}{y_1 + \mu_i Z} + \frac{f_2}{y_2 + \mu_j Z} \right] + \frac{(c_1 c_j)^2}{4 \mu_Z (y_1 + \mu_i A)} \left[ \frac{f_1}{y_1 + \mu_i A} + \frac{f_2}{y_2 + \mu_j Z} \right] + \left\{ (y_1, \mu_i) \leftrightarrow (y_2, \mu_j) \right\}
\]

(A.3)

with

\[
a_{ij} = \left[ \frac{d_1 \lambda_{H_I H_J}}{y_3 - \mu_{1Z}} + \frac{d_2 \lambda_{H_I H_J}}{y_3 - \mu_{2Z}} \right] + \frac{2 d_1 d_j}{y_1 + \mu_i Z} + \frac{2 d_1 d_j}{y_2 + \mu_j Z} + \delta_{ij}
\]

(A.4)

The coefficients \( f_0 \) to \( f_3 \) are given by

\[
\begin{align*}
  f_0 &= \mu_Z [(y_1 + y_2)^2 + 8 \mu_Z]/8 \\
  f_1 &= (y_1 - 1)^2 (\mu_Z - y_1)^2 - 4 \mu_i y_1 (y_1 + y_i \mu_Z - 4 \mu_Z) \\
  &+ \mu_Z (\mu_Z - 4 \mu_i) (1 - 4 \mu_i - \mu_Z^2 + (\mu_i - \mu_j)^2) [y_1(y_1 - 2) + 1 - 4 \mu_i] \\
  &+ (\mu_i - \mu_j) [2 \mu_i (y_1 - y_i - 2 \mu_i) + 2 y_i \mu_Z (y_1 - 2) + 2 \mu_Z + 2 y_1 (y_1 - 1)^2] \\
  f_2 &= \mu_Z (1 + \mu_Z - y_1 - y_2 - 8 \mu_i) - (1 + \mu_Z) y_1 y_2 (2 + 2 \mu_Z - y_1 - y_2)
\end{align*}
\]
The double differential cross section of the process $e^+e^- \rightarrow Zhh$.

Appendix B: Triple Higgs Boson Production

The differential cross section of the process $e^+e^- \rightarrow ZAA$ is given by inserting $Z_{33}$ in eq. (A.2):

$$Z_{33} = a_{33} f_0 + \frac{a_{33}}{2} \left[ \frac{c_1^2}{y_1 - \mu_{1A}} + \frac{c_2^2}{y_1 - \mu_{2A}} \right] f_3$$

$$+ \frac{1}{4\mu_Z} \left[ \frac{c_1^2}{y_1 - \mu_{1A}} + \frac{c_2^2}{y_1 - \mu_{2A}} \right] \left[ \frac{c_1^2}{y_2 - \mu_{1A}} + \frac{c_2^2}{y_2 - \mu_{2A}} \right] f_2$$

$$+ \frac{1}{4\mu_Z} \left[ \frac{c_1^2}{y_1 - \mu_{1A}} + \frac{c_2^2}{y_1 - \mu_{2A}} \right]^2 f_1 + \left\{ y_1 \leftrightarrow y_2 \right\}$$

(A.6)

where

$$a_{33} = \left[ \frac{d_1 \lambda_{HAA}}{y_3 - \mu_{1Z}} + \frac{d_2 \lambda_{HAA}}{y_3 - \mu_{2Z}} \right] + \frac{1}{\mu_Z}$$

(A.7)

The coefficients $f_0$ to $f_3$ follow from the previous subsection after substituting $\mu_1, \mu_2 \rightarrow \mu_A$.

Appendix B: Triple Higgs Boson Production

The cross sections for the triple Higgs boson production of MSSM Higgs bosons, $e^+e^- \rightarrow AH_iH_j$ and $e^+e^- \rightarrow AAA$ with $H_{i,j} = h, H$ are presented in this second appendix. The remaining process $e^+e^- \rightarrow H_iAA$ does not occur at tree level because of CP–invariance.

B1: $e^+e^- \rightarrow AH_iH_j$

The double differential cross section of the process $e^+e^- \rightarrow AH_iH_j$ for unpolarized beams reads in the same notation as above:

$$\frac{d\sigma}{dx_1 dx_2} = \frac{G_F^3 M_Z^6}{768\sqrt{2}\pi^3 s} \frac{v^2_c + a^2_e}{(1 - \mu^2_Z)^2} \mathcal{A}_{ij}$$

(B.1)
with the function $\mathcal{A}_{ij}$

$$
\mathcal{A}_{ij} = \left[ \frac{\lambda_{HH,HJ,c_1}}{y_3 - \mu_{1A}} + \frac{\lambda_{HH,HJ,c_2}}{y_3 - \mu_{2A}} \right]^2 g_0 + \frac{\lambda_{H,AA}^2 c_i}{(y_1 + \mu_{1A})^2} g_1 + \frac{\lambda_{H,AA}^2 c_j^2}{(y_2 + \mu_{2A})^2} g_1'
+ \frac{c_i^2 d_i}{(y_1 + \mu_{1A})^2} g_2 + \frac{c_j^2 d_j}{(y_2 + \mu_{2A})^2} g_2' + \left[ \frac{\lambda_{HH,HJ,c_1}}{y_3 - \mu_{1A}} + \frac{\lambda_{HH,HJ,c_2}}{y_3 - \mu_{2A}} \right] ^2 g_3
\times \lambda_{H,AA} \lambda_{H,AA} c_i d_i
\left[ \frac{\lambda_{H,AA} c_i}{y_1 + \mu_{1A}} + \frac{\lambda_{H,AA} c_j}{y_2 + \mu_{2A}} \right] g_4 + \frac{c_i d_i}{(y_1 + \mu_{1A})^2} g_5 + \frac{c_j d_j}{(y_2 + \mu_{2A})^2} g_5'
+ \lambda_{H,AA} \lambda_{H,AA} c_i d_i
\left[ \frac{\lambda_{H,AA} c_j}{y_1 + \mu_{1A}} + \frac{\lambda_{H,AA} c_i}{y_2 + \mu_{2A}} \right] g_6 + \frac{c_i d_j}{(y_1 + \mu_{1A})^2} g_6 + \frac{c_j d_i}{(y_2 + \mu_{2A})^2} g_6'
+ \lambda_{H,AA} \lambda_{H,AA} c_i c_j d_j
\left[ \frac{\lambda_{H,AA} c_i}{y_1 + \mu_{1A}} + \frac{\lambda_{H,AA} c_j}{y_2 + \mu_{2A}} \right] g_7 + \frac{c_i c_j d_j}{(y_1 + \mu_{1A})^2} g_7 + \frac{c_j c_i d_i}{(y_2 + \mu_{2A})^2} g_7'
(B.2)
$$

The following expressions must be inserted for the coefficients $g_k$:

$$
g_0 = \mu_Z [(y_1 + y_2)^2 - 4\mu_A]
$$
$$
g_1 = \mu_Z (y_1^2 - 2y_1 - 4\mu + 1)
$$
$$
g_2 = \mu_Z (2y_1 + y_1^2 - 4y_2 + 4y_1^2 + 4y_1 y_2 + 1 + 4\mu_i - 8\mu_j - 8\mu_A) + (\mu_j - 2\mu - 1)
$$
$$
g_3 = 2\mu_Z (y_1^2 - 2y_1 - 4\mu + 1)
$$
$$
g_4 = 2\mu_Z (y_1 + y_1^2 - 4y_2 + 4y_1^2 + 4y_1 y_2 + 1 + 4\mu_i - 8\mu_j - 8\mu_A) + (\mu_j - 2\mu - 1)
$$
$$
g_5 = 2\mu_Z (y_1 + y_1^2 - 4y_2 + 4y_1^2 + 4y_1 y_2 + 1 + 4\mu_i - 8\mu_j - 8\mu_A) + (\mu_j - 2\mu - 1)
$$
$$
g_6 = 2\mu_Z (y_1^2 - 2y_1 - 4\mu + 1)
$$
$$
g_7 = 2\mu_Z (y_1^2 - 2y_1 - 4\mu + 1)
$$
$$
g_8 = 2 \{ \mu_Z (y_1 + y_2 + y_2^2 + 2y_2 + 5y_1 y_2 - 1 + 2\mu_j + 2\mu_i - 10\mu_A) + (\mu_i - \mu_A) (y_1 + y_2 + y_1 y_2 + 2\mu_j + 2\mu_i - 10\mu_A) \}
$$

and

$$
g'_k(y_1, y_2, \mu_i, \mu_j) = g_k(y_2, y_1, \mu_j, \mu_i)
(B.4)$$
Appendix C: Heavy Higgs Production in $W_L W_L$ Fusion

In this third appendix we list the amplitudes and cross sections for the pair production of the CP–even Higgs bosons in the longitudinal $W$ approximation $W_L W_L \rightarrow H_i H_j$, as well as for $W_L W_L \rightarrow AA$. The notation is the same as in section 2.2.

C1: $W_L W_L \rightarrow H_i H_j$

The amplitudes for the process $W_L W_L \rightarrow H_i H_j$ are given by:

$$\mathcal{M}_{LL} = \frac{G_F \hat{s}}{\sqrt{2}} \left\{ (1 + \beta_W^2) \left[ \delta_{ij} + \frac{\lambda_{H_i H_j} d_1}{(\hat{s} - M_{H_i}^2)/M_W^2} + \frac{\lambda_{H_i H_j} d_2}{(\hat{s} - M_{H_i}^2)/M_Z^2} \right] + \frac{d_i d_j}{\beta_W \lambda_{ij}} \left[ r_W + (\beta_W - \lambda_{ij}) \cos \theta \right]^2 \right. - \frac{r_W + (\beta_W + \lambda_{ij}) \cos \theta}{\cos \theta + x_W} \left. \right\}$$

(C.1)

where $\mu_{i,j} = M_{H_{i,j}}^2/\hat{s}$, $\beta_W = (1 - 4 M_W^2/\hat{s})^{1/2}$ and $\lambda_{ij}$ is the usual two–body phase space function, $\lambda_{ij}^2 = (1 - \mu_i - \mu_j)^2 - 4 \mu_i \mu_j$. Furthermore,

$$x_W = (1 - \mu_i - \mu_j)/(\beta_W \lambda_{ij})$$

$$r_W = 1 - \beta_W^2 - \beta_W^2 (\mu_i - \mu_j)^2$$

$$x_+ = (1 - \mu_i - \mu_j + 2 M_{H_i}^2/\hat{s} - 2 M_W^2/\hat{s})/(\beta_W \lambda_{ij})$$

$$r_+ = -\beta_W^2 (\mu_i - \mu_j)^2$$

(C.2)

The total cross section of the subprocess is obtained by integrating the squared amplitude over the scattering angle; the result may be written:

$$\sigma_{LL}(H_i H_j) = \frac{1}{1 + \delta_{ij}} \frac{G_F^2 M_W^4}{2 \pi \hat{s}} \frac{\lambda_{ij}}{\beta_W (1 - \beta_W^2)^2} \left\{ (1 + \beta_W^2) \left[ \delta_{ij} + \frac{\lambda_{H_i H_j} d_1}{(\hat{s} - M_{H_i}^2)/M_W^2} + \frac{\lambda_{H_i H_j} d_2}{(\hat{s} - M_{H_i}^2)/M_Z^2} \right]^2 \right. \frac{2 (1 + \beta_W^2)}{\beta_W \lambda_{ij}} \left[ \delta_{ij} + \frac{\lambda_{H_i H_j} d_1}{(\hat{s} - M_{H_i}^2)/M_W^2} + \frac{\lambda_{H_i H_j} d_2}{(\hat{s} - M_{H_i}^2)/M_Z^2} \right] [d_i d_j a_1^W + c_{ij} a_1^+] + \left. \left( \frac{d_i d_j}{\beta_W \lambda_{ij}} \right)^2 a_2^W + \left( \frac{c_{ij}}{\beta_W \lambda_{ij}} \right)^2 a_2^+ + 4 \left( \frac{d_i d_j c_{ij}}{\beta_W^2 \lambda_{ij}^2} \right) [a_3^W + a_3^+] \right\}$$

(C.3)

with

$$a_1^W = \left[ (x_W \lambda_{ij} - \beta_W)^2 + r_W \right] \log \frac{x_W - 1}{x_W + 1} + 2 \lambda_{ij} (x_W \lambda_{ij} - 2 \beta_W)$$

$$a_2^W = \left[ \frac{1}{x_W} \log \frac{x_W - 1}{x_W + 1} + \frac{2}{x_W^2 - 1} \right] \left[ x_W^2 \lambda_{ij}^2 (3 \lambda_{ij} x_W^2 + 2 r_W + 14 \beta_W^2) \right]$$

$$- (\beta_W + r_W)^2 - 4 \lambda_{ij} \beta_W x_W (3 \lambda_{ij} x_W^2 + \beta_W + r_W)$$

$$- \frac{4}{x_W^2 - 1} \left[ \lambda_{ij}^2 (\lambda_{ij} x_W^2 + 4 \beta_W^2 - 4 \lambda_{ij} x_W \beta_W) - (\beta_W + r_W)^2 \right]$$

32
\[
a_3^W = \frac{1}{x_+ - x_W} \log \frac{x_W - 1}{x_W + 1} \left[ 2\beta_W \lambda_{ij} x_W (\beta_W^2 + \lambda_W^2) (x_W + x_W) + x_W r_W + x_+ r_+ \right] - x_+ (r_+ + r_W + \lambda_{ij}^2 x_W (\beta_W^2 + \lambda_W^2) x_W - \beta_W^2 (x_+ \beta_W^2 + 4 \lambda_{ij}^2 x_W^2 + x_+ x_W \lambda_{ij}^2) - x_+ r_W r_+ + \lambda_{ij}^2 [\lambda_W^2 x_+ x_W - 2 \beta_W \lambda_{ij} (x_W + x_+) + 4 \beta_W^2] \right]
\]

\[
a_i^+ \equiv a_i^W \ (x_W \leftrightarrow x_+, \ r_W \leftrightarrow r_+)
\]

**C2: \( W_L W_L \rightarrow AA \)**

For pseudoscalar Higgs bosons, amplitude and cross section are significantly simpler since only a few diagrams contribute to the \( AA \) final state and, moreover, the masses of the final-state particles are equal:

\[
M_{LL} = \frac{G_F \hat{s}}{\sqrt{2}} \left\{ (1 + \beta_W^2) \left[ 1 + \frac{\lambda_{hAA} d_1}{(s - M_h^2)/M_Z^2} + \frac{\lambda_{HAA} d_2}{(s - M_{h^2})/M_Z^2} \right] + \frac{1}{\beta_W \beta_A} \left[ (\beta_W - \beta_A \cos \theta)^2 - (\beta_W + \beta_A \cos \theta)^2 \right] \right\}
\]

with

\[
\beta_A = (1 - 4 M_A^2 / \hat{s})^{1/2} \quad \text{and} \quad x_A = (1 - 2 M_A^2 / \hat{s} + 2 M_{h^2} / \hat{s} - 2 M_W^2 / \hat{s}) / (\beta_W \beta_A)
\]

The total cross section for the subprocess \( W_L W_L \rightarrow AA \) may be cast into the form

\[
\sigma_{LL}(AA) = \frac{G_F^2 M_W^4}{4 \pi \hat{s}} \beta_W (1 - \beta_W^2)^2 \left\{ (1 + \beta_W^2) \left[ 1 + \frac{\lambda_{hAA} d_1}{(s - M_h^2)/M_Z^2} + \frac{\lambda_{HAA} d_2}{(s - M_{h^2})/M_Z^2} \right]^2 \right\}
\]

\[
\times \left[ (x_A \beta_A - \beta_W)^2 \log \frac{x_A - 1}{x_A + 1} + 2 \beta_A (x_A \beta_A - 2 \beta_W) \right] + \frac{1}{\beta_W^2} \times \left\{ \log \frac{x_A - 1}{x_A + 1} \left[ (3 \beta_A^2 x_A (\beta_A x_A - 2 \beta_W)^2 + \beta_W^2 (2 \beta_A^2 x_A - 4 \beta_W \beta_A - \beta_W^2 / x_A) \right] + \frac{2}{x_A^2 - 1} \left[ (3 x_A^2 \beta_A^2 - 2 \beta_A^2 + 2 \beta_W) (\beta_A x_A - 2 \beta_W)^2 + \beta_W^2 (2 x_A^2 \beta_A - 3 \beta_W^2) \right] \right\}
\]

**C3: Asymptotia**

For asymptotic energies, the leading part of the \( WW \) cross sections does not involve the trilinear couplings \( H_i H_j H_k \) or \( H_i H_j A \). Note however that the convoluted leptonic cross sections \( e^+ e^- \rightarrow \nu \bar{\nu} H_i H_j \) and \( AA \) are dominated by the threshold regions, also for asymptotic \( e^+ e^- \) energies, so that the observable leptonic high-energy cross sections are indeed sensitive in leading order to the trilinear Higgs couplings.
