Abstract.
Using a Lax pair based on twisted affine $sl(2,\mathbb{R})$ Kac-Moody and Virasoro algebras, we deduce a $r$-matrix formulation of two dimensional reduced vacuum Einstein's equations. Whereas the fundamental Poisson brackets are non-ultralocal, they lead to pure $c$-number modified Yang-Baxter equations. We also describe how to obtain classical observables by imposing reasonable boundaries conditions.

1 Introduction

Quantization of gravitation is still today, one of the most challenging problem in theoretical physics. A possible approach consists in trying simpler models, to have an idea of what happens when passing from classical theory to the quantum one. The case of two commuting Killing vector reduction of source-free general relativity, is probably one of the most interesting. This model has the particularity to exhibit an infinite dimensional symmetry group, the so-called Geroch group [1], and it is known to be integrable since the works of Belinskii, Zakharov and Maison [2, 3]. One way to quantize is to apply methods used for standard integrable models. This quantization problem, which is equivalent to \( \text{SL}(2, \mathbb{R})/\text{SO}(2) \) coset space \( \sigma \)-models coupled to two-dimensional gravity and a dilaton (it can be generalized to \( G/H \) coset space), has been of course the subject of several papers ([4, 5] and references therein).

Before trying to quantize this system, it is necessary to study in details the Poisson algebra. Moreover, the classical theory is also interesting for its own. An extensive work has already been done in this domain by Julia, Korotkin, Nicolai and Samtleben [4, 5, 6]. A dynamical \( r \)-matrix formulation of the model has been proposed (see e.g. [5]) where the dilaton is given a priori. A restriction of this approach is that the brackets are evaluated on the constraint surface, which prevents deduction of the associated Yang-Baxter equations. In [7], an expression was proposed for the Lax connection, based on twisted \( \mathfrak{sl}(2, \mathbb{R}) \) affine Kac-Moody and Virasoro algebras, that reproduces the equations of motion. Using dressing transformations, it provides a rather elegant method to generate solutions [8]. The aim of this article is to show that this form of the Lax connection can also provide a good basis to obtain \( r \)-matrices formulation of this problem. This means that all fields are considered as dynamical variables and pure \( c \)-number Yang-Baxter equations can be deduced. The structure we obtain is closed to Toda affine model’s one. We hope that we will be able to transpose what have been done in this domain to our problem. This will provide an alternative algebraic approach for the quantization of 2d reduced gravity and thus a complementary point of view to what has already been done.

This paper is organized as follow. Section 2 sums up some of the main results of [7], in particular we introduce the Lax pair. Section 3 deals with the Hamiltonian formulation of the theory. The calculation of the Poisson brackets of the Lax connection, the key point of this paper, and the deduction of the associated Yang-Baxter equations are described in section 4. We show that despite the \( r \)-dynamical behavior of the model, we obtain pure \( c \)-number modified Yang-Baxter relations of kind

\[
[r_{12}^{c_1}, r_{23}^{c_2}] + [s_{23}^{c_2}, s_{31}^{c_1}] + [s_{31}^{c_3}, r_{12}^{c_1}] - \frac{1}{2}k_2 s_{31}^{c_3} - \frac{1}{2}k_3 r_{12}^{c_1} - \frac{1}{4}[U_{23}, c_{12}] = 0
\]

that can be interpreted as as consistency conditions for a simpler static linear model (but still lack of a quadratic interpretation). As an application of the previous results, we determine the Poisson brackets of monodromy matrices in section 5, and we point out the problem of coincident values. Section 6 is an attempt to find classical observables. We show that if we impose reasonable boundaries conditions, it is possible to construct an infinite set of these objects. Finally, we have gathered in Appendix A and B, some expressions and sketches of demonstrations related to section 4.

2 Equation of motion and Lax connection

In this section, we will review some basics facts and results found in [7]. We will also introduce notations used in this article. Let recall the parameterization we choose for the metric:

\[
ds^2 = \rho^2 e^{2\sigma}(-dt^2 + dx^2) + \rho S_{ij}(x,t)dy^i dy^j
\]

(1)
where $\rho$ is called the dilaton and $\tilde{\sigma}$ the conformal factor. The symmetric $2 \times 2$ matrix $S$, normalized by $\text{det}(S) = 1$, can be written as $S = V^t V$, where $V$ is an element of $SL(2,R)$. $V$ is equivalent to internal zweibein, up to a $\sqrt{\rho}$ factor. There is a manifest local $SO(2)$ gauge symmetry when multiplying $V$ to the left with any element of $SO(2)$.

We introduce the decomposition of $sl(2,R) = h \oplus g$ where $h = so(2)$ is the maximal compact subalgebra of $sl(2,R)$. We will use the semi direct product of this algebra with the Virasoro’s one. We recall that the notation for two elements of the Virasoro algebra

\[
\begin{align*}
\{L_n, X\} = L_{n+m} + mX^n + nY^m, \\
(\partial_x \rho) (\partial_x \rho) \tilde{\sigma} = -\rho \frac{1}{2} \text{tr} ( (P_x + P_t)^2 )
\end{align*}
\]

Before dealing with the Lax connection, we shall introduce the algebra we will use. Consider the $sl(2,R)$ affine Kac-Moody algebra defined by the commutation relations:

\[
[X \lambda^n, Y \lambda^m] = [X, Y] \lambda^{m+n} + n \frac{k}{2} \text{tr} (XY) \delta_{n+m,0}
\]

We twist this algebra with the order two automorphism that leaves $h$ invariant. It means that for some element $X \lambda^n$, if $n$ is even, then $X$ is an element of $h$, else $X$ is an element of $g$. In fact, we will use the semi direct product of this algebra with the Virasoro’s one. We recall that the commutation relations for the Virasoro algebra are

\[
[L_n, L_m] = (n-m)L_{m+n} + n(n^2-1)\frac{k}{12} \delta_{n+m,0}
\]

and the crossed Lie bracket is $[L_n, X \lambda^m] = -\frac{m}{2} X \lambda^{n+m}$. For convenience, we introduce a particular notation for two elements of the Virasoro algebra $E_{\pm} = L_0 - L_{\pm 1}$ which verify the commutation relation $[E_+, E_-] = E_+ + E_-$. 

As we said before, the model is integrable. It means that an auxiliary linear system

\[
(\partial_t + A_t) \Psi = 0 \quad \text{and} \quad (\partial_x + A_x) \Psi = 0
\]

can be found such that the zero curvature condition $[\partial_t + A_t, \partial_x + A_x] = 0$ reproduces the equations of motion. The expression of the components of Lax connection that fulfills this requirement, is

\[
A_x = -\frac{1}{2} \rho^{-1} (\Pi_{\rho} - \partial_x \rho) E_+ - \frac{1}{2} \rho^{-1} (\Pi_{\rho} + \partial_x \rho) E_- + \frac{1}{2} (P_{xa} + P_{ta}) T^a \lambda
\]
\[+ \frac{1}{2} (P_{xa} - P_{ta}) T^a \lambda^{-1} + Q_{xa} T^a + \Pi_{\rho} k \]
\]

\[
A_t = -\frac{1}{2} \rho^{-1} (\Pi_{\rho} - \partial_x \rho) E_+ + \frac{1}{2} \rho^{-1} (\Pi_{\rho} + \partial_x \rho) E_- + \frac{1}{2} (P_{xa} + P_{ta}) T^a \lambda
\]
\[+ \frac{1}{2} (P_{xa} - P_{ta}) T^a \lambda^{-1} + Q_{ta} T^a - \partial_x \tilde{\sigma} k \]
where \( \Pi_\sigma = -\partial_t \rho \) and \( \Pi_\rho = -\partial_t \sigma \).

We will often use the notation \( A^\alpha \) for \( A_x \) and the term connection for the Lax connection (from now, we will deal no more with the connection \( V \partial V^{-1} \), so there will be no misunderstanding). Notice that the zero curvature condition reproduces the equations of motion (2) to (5) and a second order equation for \( \sigma \)

\[
\left( \partial^2_t - \partial^2_x \right) \sigma = -\frac{1}{2} tr \left( P_x^2 - P_t^2 \right)
\]

which is a consequence of the two linear equations for the conformal factor (6).

This form of the connection was first used as the key of powerful method to generate solutions to Einstein’s equations. Readers who are interested, can found details in [7] and [8]. When comparing with other Lax connection used in literature (see e.g.[4, 5]), we remark that all fields are considered on an equal footing (in general, the dilaton is supposed to be given and the conformal factor is deduced from the other variables). So, if we want to consider all of them at the same time, this connection seems to be a good candidate. We will see that it introduces no additional difficulty and, at the contrary, yields simpler and more compact expressions for the Poisson brackets for the connection.

3 Action and canonical brackets

The hamiltonian formulation of 2d reduced of gravity, has been already studied in various papers [6, 4, 5]. So, up to some minor changes, the formulation we shall use is identical to what can be found in the literature. Let us recall it.

First of all, let describes our phases space. It is defined by the canonical variables \( P_x, Q_x, \rho, \sigma \) and their associated momenta \( \Pi_P, \Pi_Q, \Pi_\rho, \Pi_\sigma \). Here we use the canonical Poisson brackets to define the symplectic structure \( \{ \rho(x), \Pi_\rho(y) \} = \delta(x-y) \) and so on).

To make contact with the model, we have to express the quantities \( P_t \) and \( Q_t \) in terms of the canonical variables. We also need the generators of the transformations associated to the invariances of our system which are invariance under reparameterization and the local \( SO(2) \) invariance. To solve this problem, we can either try to deduce these formulae from some mathematical procedures (see [5] for example), or just give expressions as definition and verify if this choice is coherent. Here, we will adopt the second method. First we define the variable \( P_t \) as

\[
-\rho P_t = \partial_x \Pi_P + [Q_x, \Pi_P] + [P_x, \Pi_Q]
\]

\( Q_t \) will be considered to have vanishing brackets with all variables.

This phases space is reduced by the three constraints arising from the gauge invariance mentioned above. First we have the Hamiltonian \( \mathcal{H} \) which can be written as

\[
\mathcal{H} = -\Pi_\rho \Pi_\sigma - \partial_x \rho \partial_x \sigma + \frac{1}{2} \rho tr \left( P_t^2 + P_x^2 \right) + tr \left( Q_t \Phi \right)
\]

With this expression for the Hamiltonian, the equations of motion (2-5 and 11) are correctly reproduced (the brackets needed for these calculations are given below). We still have two other generators of gauge transformations. We denote \( \mathcal{P} \) the generator of diffeomorphisms in the spatial direction whose expression is

\[
\mathcal{P} = \Pi_\rho \partial_x \rho + \Pi_\sigma \partial_x \sigma + \rho tr \left( P_t P_x \right) + tr \left( Q_x \Phi \right)
\]

The linear combinations \( C_\pm = \mathcal{H} \pm \mathcal{P} \approx 0 \) of these two constraints, are just the equivalent of the two linear equations for the conformal factor (6). Finally, the generator \( \Phi \) of the \( SO(2) \) gauge invariance takes the following form

\[
-\Phi = \partial_x Q_x + [Q_x, \Pi_Q] + [P_x, \Pi_P]
\]
It could be easily verified that $\Phi$ belongs to $so(2)$. Notice that all these constraints are first class constraints.

We will use the standard index-free tensor notation. For some element $X$, we define $X_1 \equiv X \otimes I$ and $X_2 \equiv I \otimes X$. We will also introduce the decomposition of the Casimir element $C_{12}$ of $sl(2,R)$: $C_{12} = c_{12} + d_{12}$ with $c_{12} = T^a \otimes T_a$ and $d_{12} = T^a \otimes T_a$. The validity of this decomposition is due to orthogonality of generators with respect to the Killing form.

We shall list all the basic Poisson brackets needed for further calculations.

$$
\{P_{t1}(x), P_{t2}(y)\} = \rho^{-2}(x) \delta(x - y) [d_{12}, \Phi_2(x)]
$$

$$
\{P_{t1}(x), P_{x2}(y)\} = \rho^{-1}(x) \delta(x - y) d_{12} + \rho^{-1}(x) \delta(x - y) [d_{12}, Q_{x2}(x)]
$$

$$
\{P_{t1}(x), Q_{x2}(y)\} = \rho^{-1}(x) \delta(x - y) [d_{12}, P_{x2}(x)]
$$

$$
\{\Phi_1(x), \Phi_2(y)\} = \delta(x - y) [c_{12}, \Phi_2(x)]
$$

$$
\{P_{x1}(x), \Phi_2(y)\} = -\delta(x - y) [c_{12}, P_{x1}(x)]
$$

$$
\{Q_{x1}(x), \Phi_2(y)\} = \delta'(x - y) c_{12} + \delta(x - y) [c_{12}, Q_{x2}(x)]
$$

The four last commutators show that $\Phi$ is the generator of the local $SO(2)$ invariance. Equivalent calculations can be done to prove the validity of the other generators expressions.

### 4 Poisson brackets for the Lax connection

#### 4.1 Main result

Now that we have defined the Poisson algebra, we can deduced the Poisson bracket for the Lax connection (the so-called fundamental Poisson brackets). The raw formula derived from a direct calculation, is quite long and has no pedagogic interest. We don’t write its expression (readers who want to obtain it, will encounter no difficulty). What is really interesting, is that it can be put on a r-matrix form. A brief survey of the method used to find this expression, is described in Appendix A. The result we have obtained is

$$
\{A_1(x), A_2(y)\} = \frac{1}{\rho(x)} \delta(x - y) \left( [r_{12}^+, A_1(x)] + [s_{12}^+, A_2(x)] \right) + \left( \frac{1}{\rho(x)} s_{12} - \frac{1}{\rho(y)} r_{12} \right) \partial_x \delta(x - y)
$$

$$
+ \frac{1}{8 \rho^2(x)} \delta(x - y) \left[ U_{12}, \Phi_1(x) - \Phi_2(x) \right]
$$

where

$$
U_{12} = d_{12}(\lambda_1 - \lambda_1^{-1})(\lambda_2 - \lambda_2^{-1})
$$

This formula is the one obtained in the case of non-ultralocal theories [9] with an additional term coming from the local $SO(2)$ invariance, that has to be considered with caution when dealing with the Jacobi identity. Here is the expressions of the r- and s-matrices :

$$
r_{12}^\pm = \frac{1}{2} \frac{(1 - \lambda_1^2)(1 - \lambda_2^2)}{\lambda_1^2 - \lambda_2^2} c_{12} + \frac{1}{2} \frac{\lambda_1 \lambda_2^{-1}(1 - \lambda_2^2)^2}{\lambda_1^2 - \lambda_2^2} d_{12} \pm \frac{1}{2} \left( E_\pm \otimes k + \frac{1}{2} k \otimes (E_+ + E_-) \right)
$$

$$
s_{12}^\pm = \frac{1}{2} \frac{(1 - \lambda_1^2)(1 - \lambda_2^2)}{\lambda_1^2 - \lambda_2^2} c_{12} + \frac{1}{2} \frac{\lambda_1^{-1} \lambda_2(1 - \lambda_2^2)^2}{\lambda_1^2 - \lambda_2^2} d_{12} \pm \frac{1}{2} \left( k \otimes E_+ + \frac{1}{2} (E_+ + E_-) \otimes k \right)
$$
The matrices involved here are pure c-number, all coordinates dependencies have been factorized in the \( \rho^{-1} \) factors. The rational functions that appear in (17) and (18), have only a meaning as formal power series. So, whether we choose \( |\lambda_1| < |\lambda_2| \) or \( |\lambda_1| > |\lambda_2| \) when developing, we obtain two different sets of matrices (here + convention refers to the case \( |\lambda_1| < |\lambda_2| \)). Fully developed formulas are given in appendix A.

If our Lax connection is not exactly the same that the one used by Korotkin and Samtleben in [5], however, it is possible to compare some pieces of (16) with their expression. The algebra we used, is just a way to eliminate the coordinates dependence of the moving poles. In order to compare the two formulae, we have to restore this dependence. It can be achieved by formally substituting \( \frac{1}{1 + \lambda} \) by \( \gamma \) where \( \gamma \) is the moving pole (a detailed explanation of this equivalence can be found in [8]). One can see now, their ultralocal part of the Poisson brackets for the connection are equivalent to our if we just keep the loop part of the r-matrices (remember that the introduction of the central extension \( k \) and the Virasoro algebra, is a method to take \( \rho \) and \( \delta \) into account). The case of the non-ultralocal part is more difficult because of the dilaton which produces additional terms, so no direct comparison can be done. Notice that their brackets is calculated on the constraint surface, thus they have no additional term involving \( \Phi \) and they can’t explicitly verify the Jacobi identity (which imply that Yang-Baxter equations can’t be found).

Now, the fundamental Poisson brackets have to satisfy standard relations of Poisson brackets and to be independent of the convention we choose. We will focus here on antisymmetry and independence, dealing with the Jacobi identity in the next subsection. Proofs of these two properties lie on the same relations of the r-matrices, that can be divided into two sets. On one hand, there is a set a pure numerical identities :

\[
\begin{align*}
    r_{12}^r &= -s_{21}^{r} \\
    r_{12}^r - r_{12}^{-r} &= s_{12}^{r} - s_{12}^{r} \\
    U_{12} &= U_{21}
\end{align*}
\]  

(19)

and on the other hand, we have got a relation involving connection and dilaton :

\[
[r_{12}^r - r_{12}^{-r}, A_1 + A_2] = -\rho^{-1} \partial_x \rho (r_{12}^r - r_{12}^{-r})
\]  

(20)

Using these formulae, antisymmetry and independence can be easily shown. For example, from eq.(19), we have

\[
\{A_1(x), A_2(y)\} |_{\rho=+} - \{A_1(x), A_2(y)\} |_{\rho=-} = \rho^{-1}(x)[r_{12}^r - r_{12}^{-r}, A_1(x) + A_2(x)] \delta(x-y) \\
+ (r_{12}^r - r_{12}^{-r}) \left( \rho^{-1}(x) - \rho^{-1}(y) \right) \partial_x \delta(x-y)
\]

Now with eq.(20) and the identity \( \rho^{-1}(x) - \rho^{-1}(y) \partial_x \delta(x-y) = \rho^{-2}(x) \partial_x \rho \delta(x-y) \), we easily prove that the right hand-side of the above equation vanishes.

Notice that in more conventional cases like Toda field theories, only numerical relations are used. In particular the difference \( r_{12}^r - r_{12}^{-r} \) is generally proportional to the Casimir tensor which would simplify (20). This more complicated form is a consequence of the \( \rho^{-1} \) terms in (16).

### 4.2 Jacobi identity and Yang-Baxter equations

Finally, we have to prove the validity of the Jacobi identity. Performing the calculation leads to the following formula :

\[
\{A_1(x), \{A_2(y), A_3(z)\}\} + \text{perm.} = \rho^{-2}(x)\delta(x-y)\delta(y-z) ([A_1(x), A_{123}] + \text{perm.}) \\
+ \left( \partial_x \rho^{-2} \right) \delta(x-y)\delta(y-z) (B_{123} + \text{perm.})
\]  

(21)
gauge invariance generates the term $\rho^{-3}(x)\delta(x-y)\delta(y-z)([\Phi_1(x), C_{123}]+\text{perm.}) + \rho^{-2}(x)\delta(y-z)\partial_y\delta(x-y)D_{123} + \text{perm.}$

Explicit expressions of $A_{123}$, $B_{123}$, $C_{123}$ and $D_{123}$ are gathered in appendix B. The fact that eq.(21) is equal to zero, is a consequence of the properties of $A_{123}$ and $C_{123}$. One can shown they are invariant under cyclic permutations and equal to zero (we left details in appendix B). This leads to the modified Yang-Baxter equations

$$[r_{12}^\epsilon, r_{23}^\zeta] + [s_{23}^\zeta, s_{31}^\zeta] + [s_{31}^\zeta, r_{12}^\epsilon] - \frac{1}{2}k_2s_{31}^\zeta - \frac{1}{2}k_3s_{12}^\epsilon - \frac{1}{4}[U_{23}, c_{12}] = 0 \quad (22)$$
$$[r_{23}^\zeta, U_{12}] + [s_{23}^\zeta, U_{13}] + \frac{1}{2}k_3U_{12} - \frac{1}{2}k_2U_{13} = 0 \quad (23)$$

Notice that the choice of the three conventions has to be consistent. This condition can be written as $|\epsilon_1 + \epsilon_2 + \epsilon_3| = 1$.

Thus, the validity conditions of the Jacobi identity are pure c-numbers equations. It could seem to be a miracle, especially when looking at first sight equation (16) with its explicit $\rho$ dependence. Actually this dependence is encoded in the terms involving the central extension. The $SO(2)$ gauge invariance generates the term $[U_{23}, c_{12}]$ and eq.(23). If we want to compare these Yang-Baxter equations with those obtained in simpler cases, we have to drop the central extension and the local $SO(2)$ constraint. In this case, we obtain the same results as in the case of non-ultralocal theories with constant r-matrices (see [9]).

A possible interpretation of these Yang-Baxter equations is as consistency conditions for linear Poisson brackets involving three objects $L^\pm$ and $\phi$. Defining the following algebra

$$\{L_1^+, L_2^+\} = [r_{12}^\epsilon, L_1^+], \quad \{s_{12}^\zeta, L_2^+\} + \frac{1}{2}k_2L_1^+ - \frac{1}{2}k_1L_2^+ - \frac{1}{8}[U_{12}, \phi - \phi_2]$$
$$\{L_1^+, L_2^-\} = [r_{12}^\epsilon, L_1^+], \quad \{s_{12}^\zeta, L_2^-\} + \frac{1}{2}k_2L_1^- - \frac{1}{2}k_1L_2^- - \frac{1}{8}[U_{12}, \phi - \phi_2]$$
$$\{L_1^-, L_2^+\} = [r_{12}^\epsilon, L_1^-], \quad \{s_{12}^\zeta, L_2^+\} + \frac{1}{2}k_2L_1^- - \frac{1}{2}k_1L_2^- - \frac{1}{8}[U_{12}, \phi - \phi_2]$$
$$\{L_1^+, \phi_2\} = \frac{1}{2}[L_1^+, L_2^+, c_{12}]$$
$$\{\phi_1, \phi_2\} = \frac{1}{2}[\phi - \phi_2, c_{12}]$$

We suppose that $k$ commutes with all other elements. $U_{12}$ and $c_{12}$ are considered to be symmetric when permuting the two spaces. $r_{12}$ and $s_{12}$ have to fulfilled (19) and (20) with $\rho$ constant (thus right-hand side of (20) vanishes). Under this assumptions, Yang-Baxter equations (22) and (23) can be deduced from Jacobi identity of this algebra.

Finally, remark that all these formulae are independent from the choice of $SL(2,R)/SO(2)$ coset model. The generalization to any $G/H$ coset is obvious : the tensors $c_{12}$ and $d_{12}$ have to be replaced by those of the new algebra.

5 Monodromy matrices

Now that we have determined the Poisson brackets of the Lax connection in the previous section, we can go further and calculate those of the monodromy matrices. So we want to determine $\{\Psi_1(x, x_0), \Psi_2(y, y_0)\}$, where $x > x_0$, $y > y_0$ and the four points are distinct points. The way to achieve this calculation, is as follow. Using the Leibniz rule, the only difficulty is to find the
functional derivative of $\Psi(x, x_0)$ with respect to $A(z)$. It can be done by solving the differential equations

$$
\partial_x \delta\Psi(x, x_0) + A(x) \partial^2\Psi(x, x_0) + \delta A(x) \Psi(x, x_0) = 0 \\
\partial_{x_0} \delta\Psi(x, x_0) - \partial\Psi(x, x_0) A(x_0) - \Psi(x, x_0) \delta A(x_0) = 0
$$

With the condition $\delta\Psi(x, x) = 0$, the solution is given by

$$
\delta\Psi(x, x_0) = \int_{-\infty}^{+\infty} dz \; \Theta(x-z) \; \Theta(z-x_0) \; \Psi(x, z) \; \delta A(z) \; \Psi(z, x_0)
$$

where $\Theta(x)$ is the Heaviside function ($\Theta(x) = 1$ for $x > 0$, $\Theta(x) = 0$ elsewhere). The rest of the calculations is quite easy, consisting in putting together terms to form total derivatives. Thus, we obtain the following expression:

$$
\{\Psi_1(x, x_0), \Psi_2(y, y_0)\} = -\Theta(y, y_0) \rho^{-1}(x) \; \Psi_2(y, y_0) \; r_{12}^{t} \Psi_1(x, x_0) \Psi_2(x, y_0) \\
-\Theta(y, x_0) \rho^{-1}(y) \; \Psi_1(x, y) \; s_{12}^{t} \Psi_1(y, x_0) \Psi_2(y, y_0) \\
+\Theta(y, y_0) \rho^{-1}(x_0) \; \Psi_1(x, x_0) \Psi_2(y, x_0) \; r_{12}^{t} \Psi_2(x, y_0) \\
+\Theta(y, x_0) \rho^{-1}(y_0) \; \Psi_1(x, y_0) \Psi_2(y, y_0) \; s_{12}^{t} \Psi_1(y, x_0) \\
-\frac{1}{8} \int_{-\infty}^{+\infty} dz \; \Theta(x-z) \; \Theta(z-x_0) \; \Theta(y-z) \; \Theta(z-y_0) \\
\rho^{-2}(z) \; \Psi_1(x, z) \Psi_2(y, z) \; [U_{12}, \Phi_1(z) - \Phi_2(z)] \; \Psi_1(z, x_0) \Psi_2(z, y_0)
$$

with $\Theta(x, y, z)$ equal to 1 if $x > y > z$, and 0 for the other case.

We can easily verify that these brackets are consistent. It is also a consequence of relations (19), (22), (23) and (20). This last one gives the following relation for monodromy matrices

$$
\rho^{-1}(x) \left( r_{12}^{t} - r_{12}^{-t} \right) \Psi_1(x, y) \Psi_2(x, y) = \rho^{-1}(y) \; \Psi_1(x, y) \Psi_2(x, y) \; \left( r_{12}^{t} - r_{12}^{-t} \right)
$$

We need also to evaluate the brackets between $\Psi$ and $\rho$ that can be deduced from those of $A$ and $\rho$

$$
\{A(x), \rho(y)\} = -\frac{1}{2} \delta(x-y) \; k
$$

$$
\{\Psi(x, y), \rho(z)\} = \frac{1}{2} \Theta(x-z) \; k \; \Psi(x, y) - \frac{1}{2} \Theta(y-z) \; k \; \Psi(x, y)
$$

What happens if we let the two ending points (or the two starting points) tend to the same value? In this case, we have to face to a well-known problem of non-ultralocal theories (see [10] for example) that the brackets are ill-defined (in particular, the Jacobi identity is no longer valid). In the case of non-linear sigma models, it has been shown [11] that no regularization of the Poisson brackets is coherent. One way to go beyond this problem is to have additional informations about the boundaries conditions. For example, if we consider $\rho$ as the radial coordinate, we can choose a frame such that $\rho(x)$ tends to $\infty$ when $x$ goes to a given point $x_\infty$. If we take this naive limit in eq.(24), assuming that the $\Psi(x, x_\infty)$ terms have a good behavior compared to $\rho^{-1}(x)$, we obtain the following relation

$$
\{\Psi_1(x, x_\infty), \Psi_2(y, x_\infty)\} = -\Theta(y-x) \rho^{-1}(x) \; \Psi_2(y, x_\infty) \Psi_2^{-1}(x, x_\infty) \; r_{12}^{t} \Psi_1(x, x_\infty) \Psi_2(x, x_\infty) \\
-\Theta(x-y) \rho^{-1}(y) \; \Psi_1(x, x_\infty) \Psi_2^{-1}(y, x_\infty) \; s_{12}^{t} \Psi_1(y, x_\infty) \Psi_2(y, x_\infty) \\
-\frac{1}{8} \int_{-\infty}^{+\infty} dz \; \Theta(x-z) \; \Theta(y-z) \; \rho^{-2}(z) \Psi_1(x, x_\infty) \Psi_2(y, x_\infty) \\
\Psi_1^{-1}(z, x_\infty) \Psi_2^{-1}(z, x_\infty) \; [U_{12}, \Phi_1(z) - \Phi_2(z)] \; \Psi_1(z, x_\infty) \Psi_2(z, x_\infty)
$$

8
It can be shown that the above definition, these brackets are well-defined. We focus the readers attention on the consequences of this limit for relation (25). We obtain

$$\left(r^e_{12} - r^{-e}_{12}\right) \left(\rho^{-1}(x)\Psi_1(x, x, x)\Psi_2(x, x, x)\right) = 0$$

This boundaries condition implies that $\rho^{-1}\Psi_1\Psi_2$ has to be in the kernel of $r^e_{12} - r^{-e}_{12}$, which imposes strong constraints on $\Psi$.

Can we go further? If we keep in mind the equivalence $\rho$ as the radial coordinate, it would seem interesting to consider the case $\rho = 0$. It could be a way to define an algebra for spatially independent objects. Unfortunately, it leads to more difficult problems when trying to evaluate Poisson brackets of these objects. But as we shall see in the following section, such an approach is more successful when studying physical observables.

6 Classical observables

6.1 General Framework

By definition, classical observables are functionals of the phase spaces variables that commute with the constraints. Before finding these observables, we need some preliminary calculations. First, we have to determine the commutators between the constraints and the connection:

$$\{\mathcal{H}(x), A_x(y)\} = A_t(x)\partial_x\delta(x-y) - [A_x(x), A_t(x)]\delta(x-y) - \rho^{-1}(x)\left[\Phi(x), P_t(x)\right] \delta(x-y) \quad (29)$$

$$\{P(x), A_x(y)\} = A_x(x)\partial_x\delta(x-y) \quad (30)$$

$$\{\Phi_1(x), A_x(y)\} = [c_{12}, A_x(x)]\delta(x-y) + \partial_x\delta(x-y)c_{12} \quad (31)$$

The equivalent relations for the wave function can be found by solving the differential equation associated to one of the commutators, obtained when deriving with respect to the spatial parameter of the wave function. Thus, we deduce the following identities (on the constraint surface):

$$\{\mathcal{H}(x), \Psi(y, z)\} = A_t(y)\Psi(y, z)\delta(x-y) - \Psi(y, z)A_t(z)\delta(x-z) \quad (32)$$

$$\{P(x), \Psi(y, z)\} = A_x(y)\Psi(y, z)\delta(x-y) - \Psi(y, z)A_x(z)\delta(x-z) \quad (33)$$

$$\{\Phi_1(x), \Psi_2(y, z)\} = c_{12}\Psi_2(y, z)\delta(x-y) - \Psi_2(y, z)c_{12}\delta(x-z) \quad (34)$$

Finding quantities that have vanishing brackets with the local $SO(2)$ constraint, is quite obvious. If we consider $\zeta$ defined by $\partial_\mu\zeta + Q_\mu\zeta = 0$, then it is straightforward to show that $\zeta^{-1}(x)\Psi(x, y)\zeta(y)$ commutes with $\Phi$. difficulties arise when we try to find objects invariant under diffeomorphisms. If we keep in mind what was done in simpler cases, we should attempt to consider the monodromy matrix between the boundaries. We shall see that it can be achieved by using two particular values of $\rho$ and imposing physical boundaries conditions to the solutions.

6.2 Vacuum solution and level one representations

We shall recall some formulae and results described in [7] that will be helpful when dealing with boundaries conditions. In particular, we shall introduce the level one representations for the affine algebra.

One of the most simple solution of the Einstein’s equations is the vacuum solution which corresponds to the case where all P and Q fields are null (notice there is a slightly change comparing to [7], where $\tilde{\sigma}$ is also zero). The associated Lax connection belongs to the Virasoro
they transform as matrices. We gather here all needed formulae. The case of the Virasoro algebra elements

\[ \text{Operators} \]

\[ C_j \]

and the vertex operator \( W \) algebra observables. First we introduce the two dimensional representation of \( \text{sl}(2, R) \) involving Pauli matrices

\[ T^x = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad T^y = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}, \quad T^z = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \]

Notice that \( T^y \) is the \( \text{SO}(2) \) generator. Let denote \( Z(\mu) \) the field

\[ Z(\mu) = \sum_{n \text{ odd}} p_{-n} \frac{\mu^n}{n} \text{ with } [p_n, p_m] = n \delta_{n+m,0} \]

and the vertex operator \( W_2(\mu) =: e^{-2iZ(\mu)} :. \) We denote \( |0> \) the vacuum of the Fock space generated by the operators \( p_n \). The level one representations with highest weight \( \Lambda_\pm \) are defined by

\[ i \mu \frac{dZ(\mu)}{d\mu} = \sum_{n \text{ odd}} (T^z \otimes \lambda^n) \mu^{-n} \]

\[ \pm i \quad W_2(\mu) = 2 \sum_{n \text{ even}} (T^y \otimes \lambda^n) \mu^{-n} - 2 \sum_{n \text{ odd}} (T^x \otimes \lambda^n) \mu^{-n} \]

The heighest weight vectors \( |\Lambda_\pm > \) are identified with \( |0 > \). The Virasoro generators are represented by

\[ L_n = -\frac{1}{8\pi i} \oint_{C} d\mu \mu^{2n+1} (i\partial_\mu Z)^2 + \frac{1}{16} \delta_{n,0} \]

where \( C \) is a contour around zero.

In the next subsection, we shall need to conjugate elements of the algebra by the vacuum wave function. We gather here all needed formulae. The case of the Virasoro algebra elements \( E_+ \) and \( E_- \) is quite obvious

\[ D E_+ E_- D^{-1} = D E_- + (D - 1)E_+ \quad \text{and} \quad B^{-E_-} E_+ B^{E_-} = B E_+ + (B - 1)E_- \]

Operators \( \mu^{-1}W_2(\mu) \) and \( \partial_\mu Z \) are primary fields of weight 1. Under a diffeomorphism \( \mu \rightarrow F(\mu) \), they transform as

\[ \mu^{-1}W_2(\mu) \rightarrow \frac{\mu}{2F^2} \left( \partial_\mu F^2 \right) W_2(F(\mu)) \]

\[ \partial_\mu Z \rightarrow \frac{\mu^2}{2F^2} \left( \partial_\mu F^2 \right) (\partial_\mu Z)(F(\mu)) \]

It can be proved that conjugations \( AD^{-E_+} \mu^{-1}W_2(\mu)D^{E_+} \) and \( B^{-E_-} \mu^{-1}W_2(\mu)B^{E_-} \), are associated to the following diffeomorphisms

\[ F_+^2(\mu) = \frac{\mu^2}{\mu^2 + (1 - \mu^2)D} \]

\[ F_-^2(\mu) = 1 + (\mu^2 - 1)B \]
6.3 Boundaries conditions and physical observables

Let give a brief sketch of the strategy we shall use. Following the idea proposed in [5], we shall consider $\Psi$ between the points $x_0$ where $\rho = 0$, and $x_\infty$ where $\rho \to \infty$. We shall need to define our phase space by specifying the behavior of the other fields in these limits. As we will see, it is not possible to obtain physical observables by only imposing boundaries conditions on $\Psi$. We shall construct physical observables in the form $M_0^{-1}(x_0)\Psi(x_0, x_\infty)M_\infty(x_\infty)$ in such a way the contribution of $M_0$ and $M_\infty$ to the Poisson brackets with the constraints eliminates the unwanted terms.

First we shall look at the case where $\rho \to \infty$, with the picture that in this limit, $\rho$ becomes equivalent to the usual radial coordinate (assuming it happens when $x \to x_\infty$). It seems physically reasonable to restrict our phases space to solutions which tend asymptotically to the flat space solution when $\rho \to \infty$. This solution corresponds to the Minkowski metric element expressed in cylindrical coordinates $ds^2 = -dt^2 + d\rho^2 + \rho^2 d\theta^2 + dz^2$. We shall take

$$\Pi_\rho = \Pi_\sigma = 0 \quad \sigma = -\frac{1}{4} \ln \rho \quad P_x = \rho^{-1}\sqrt{2T^z}$$

and all other components of $P$ and $Q$ equal to zero. The components of the Lax connection are

$$(A_f)_x = \rho^{-1} \left( \frac{1}{2} (E_+ - E_-) + \frac{\sqrt{2}}{2} T^z (\lambda + \lambda^{-1}) \right)$$

and

$$(A_f)_t = \rho^{-1} \left( \frac{1}{2} (E_+ + E_-) + \frac{\sqrt{2}}{2} T^z (\lambda - \lambda^{-1}) + \frac{k}{8} \right)$$

The wave function which is solution of (8) with the above connection can be written as

$$\Psi_f = \frac{h_-}{\rho + 1} \left[ \left( \frac{2\rho}{\rho + 1} \right)^{-E_-} \left( \frac{1}{2} (\rho + 1) \right)^{-E_+} \rho^{-\frac{k}{2}} h_-^{-1} \right]$$

with $h_\pm = \exp \left( \sqrt{2T^z} \ln \left( \frac{1 + \lambda^{\pm 1}}{1 - \lambda^{\pm 1}} \right) \right)$. If we look at the Lax connection, we see that it is proportional to $\rho^{-1}$. Thus, if we impose that the wave function $\Psi(x)$ tends asymptotically toward $\Psi_f(x)$ when $x \to x_\infty$, equations (32) and (33) become

$$\{H(x), \Psi(y, x_\infty)\} = A_t(y)\Psi(y, x_\infty)\delta(x - y)$$

and

$$\{P(x), \Psi(y, x_\infty)\} = A_x(y)\Psi(y, x_\infty)\delta(x - y)$$

Now let us consider the more tricky case of $\rho = 0$. We shall suppose there is a point $x_0$ such that

$$\rho(x_0) = 0 \quad \text{and} \quad \Pi_\sigma(x_0) = 0$$

In the picture of cylindrical symmetry, it means that close to the symmetry axis, $\rho$ can be identified with the usual radial coordinate. We assume $P$ behaves like $\rho^{-1}$ when $x \to x_0$. Actually, if we admit these quantities have a $\rho$ power law behavior in this limit (which seems physically reasonable), then, using equations of motion (2, 3, 4), we can show that it is the only solution. But the monodromy matrix $\Psi(x_0, x_\infty)$ is not an observable because the Lax connection diverges when $\rho \to 0$. To avoid this problem, we apply the technique explained at the beginning of this subsection: we multiply $\Psi(x, x_\infty)$ by $M_0^{-1}(x)$ with $M_0$ equal to the vacuum wave function $\Psi_V$ whose form in the limit $x \to x_0$ becomes

$$\Psi_V \sim e^{\frac{i\sigma k}{2\rho}} \left( \frac{e}{2\rho} \right)^{E+} \left( \frac{e'}{2\rho} \right)^{E-} \sim e^{\frac{i\sigma k}{2\rho}} \left( \frac{e}{2\rho} \right)^{E-} \left( \frac{e'}{2\rho} \right)^{E+}$$

(40)
The linear equations satisfied by $\Psi^{-1}_V(x)\Psi(x, x_\infty)$ are of type

$$\partial \left( \Psi^{-1}_V(x)\Psi(x, x_\infty) \right) = \left( \Psi_V(x)^{-1}\tilde{A}(x)\Psi_V(x) \right)\Psi_V(x)^{-1}\Psi(x, x_\infty)$$

where $\tilde{A}$ is the Kac-Moody algebra part of the connection (the contribution of $\Psi_V$ has canceled Virasoro and central extension parts). Poisson brackets of $\Psi^{-1}_V(x)\Psi(x, x_\infty)$ with $\mathcal{H}$ and $\mathcal{P}$ are obtained by substituting $\Psi^{-1}_V\tilde{A}\Psi_V$ to $A$ in formulae (38) and (39). To evaluate $\Psi^{-1}_V\tilde{A}\Psi_V$, we use the level one representation described in the previous subsection and the second form of (40). The diffeomorphism associated to this conjugation is $F^2(\mu) = \frac{2\rho+(\mu^2-1)c}{2\rho+(\mu^2-1)c(1-c)}$. For example, for one of the components of $A$, we have

$$\Psi^{-1}_V (P_t)_x T^x \otimes \lambda \Psi_V = \pm \frac{(P_t)_x \Psi^{-1}_V}{4\pi} \left( \oint_{\mathcal{C}} d\mu \mu W_2(\mu) \right) \Psi_V$$

$$= \pm \frac{(P_t)_x}{4\pi} \left( \frac{\rho c'}{c(c'-1)^2} W_2(1 - \frac{1-c'}{1-c}) \oint_{\mathcal{C}} d\mu \frac{\mu^2}{(\mu^2-1)^2} + O(\rho^2) \right)$$

$$= (P_t)_x \left( 0 + O(\rho^2) \right) = O(\rho) \text{ as } \rho \to 0$$

The last equation follows from the fact that $P$ is proportional to $\rho^{-1}$ as $x \to x_0$ and that the contour $\mathcal{C}$ around 0 can be chosen as small as we want, such that there is no pole contribution to the integral. Doing these calculations in the level one representation provides a way to give meaning to quantities like $W_2(\frac{1}{1-c})$, which would be ambiguous in the abstract Kac-Moody algebra.

Identical results can be obtained for the other components. Thus $\Psi^{-1}_V(x_0)\tilde{A}(x_0)\Psi_V(x_0)$ is equal to zero, whereas $A(x)$ was divergent when $x \to x_0$, and $\Psi^{-1}_V(x_0)\Psi(x_0, x_\infty)$ has null Poisson brackets with the generators of diffeomorphisms.

Defining $SO(2)$ gauge-invariant object from $\Psi^{-1}_V(x_0)\Psi(x_0, x_\infty)$ is quite straightforward. Using the technique presented in subsection 6.1 and the fact that $so(2)$ elements commute with $\Psi_V$, we can show that the quantity

$$\bar{\Psi}(x_0, x_\infty) = \zeta^{-1}(x_0)\Psi^{-1}_V(x_0)\Psi(x_0, x_\infty)\zeta(x_\infty) \quad (41)$$

still has vanishing brackets with $\mathcal{H}$ and $\mathcal{P}$, and is moreover $SO(2)$ gauge-invariant. It proves that $\bar{\Psi}(x_0, x_\infty)$ is a physical observable. Note that these are operators (i.e., infinite dimensional matrices) acting on the level one representation of $sl(2, R)$. They thus provide an infinite set of physical observables.

To summarize: We have supposed the two following boundary conditions: 1) when $\rho$ goes to infinity, the wave function tends asymptotically to the flat space wave function; 2) we can find a point $x_0$ where $\rho$ and $\Pi_\sigma$ are null. Notice that these conditions are fulfilled in concrete examples like cylindrical gravitational waves (see e.g. [12]). Using these hypotheses and the level one representations, we have shown that $\zeta^{-1}(x_0)\Psi^{-1}_V(x_0)\Psi(x_0, x_\infty)\zeta(x_\infty)$ generates an infinite set of classical physical observables. It remains to decipher the Poisson bracket algebra they generate which should be closer to those of the Toda’s theories.

7 Appendix A:

The aim of this appendix is to give more details about the Poisson brackets of the connection. First, let us write developed formulae for the r- and s-matrices:
• plus convention ($|\lambda_1| < |\lambda_2|$):

\[ r_{12}^+ = \frac{1}{2} (1 - \lambda_1^2)(1 - \lambda_2^2) \sum_{n \geq 0} \left( \frac{\lambda_1}{\lambda_2} \right)^{2n} c_{12} - \frac{1}{2} (\lambda_2 - \lambda_2^{-1}) \sum_{n \geq 0} \left( \frac{\lambda_1}{\lambda_2} \right)^{2n+1} d_{12} \]

\[ -\frac{1}{2} E_+ \otimes k - \frac{1}{4} k \otimes (E_+ + E_-) \]

\[ s_{12}^+ = \frac{1}{2} (1 - \lambda_1^2)(1 - \lambda_2^2) \sum_{n \geq 0} \left( \frac{\lambda_1}{\lambda_2} \right)^{2n} c_{12} - \frac{1}{2} (\lambda_1 - \lambda_1^{-1}) \sum_{n \geq 0} \left( \frac{\lambda_1}{\lambda_2} \right)^{2n+1} d_{12} \]

\[ -\frac{1}{2} k \otimes E_- - \frac{1}{4} (E_+ + E_-) \otimes k \]

• minus convention ($|\lambda_1| > |\lambda_2|$):

\[ r_{12}^- = -\frac{1}{2} (1 - \lambda_1^{-2})(1 - \lambda_2^2) \sum_{n \geq 0} \left( \frac{\lambda_2}{\lambda_1} \right)^{2n} c_{12} + \frac{1}{2} (\lambda_2 - \lambda_2^{-1}) \sum_{n \geq 0} \left( \frac{\lambda_2}{\lambda_1} \right)^{2n+1} d_{12} \]

\[ +\frac{1}{2} E_- \otimes k + \frac{1}{4} k \otimes (E_+ + E_-) \]

\[ s_{12}^- = -\frac{1}{2} (1 - \lambda_1^{-2})(1 - \lambda_2^2) \sum_{n \geq 0} \left( \frac{\lambda_2}{\lambda_1} \right)^{2n} c_{12} + \frac{1}{2} (\lambda_1 - \lambda_1^{-1}) \sum_{n \geq 0} \left( \frac{\lambda_2}{\lambda_1} \right)^{2n+1} d_{12} \]

\[ +\frac{1}{2} k \otimes E_+ + \frac{1}{4} (E_+ + E_-) \otimes k \]

Notice that the differences $r_{12}^+ - r_{12}^-$ and $s_{12}^+ - s_{12}^-$ are equal. But in contrary to the usual cases, they are not proportional to the Casimir tensor (see equation (20)).

In order to demystify this formulae, we will sketch the way we have obtained them. First, we consider only the loop part of the algebra and the ultralocal contribution. The more general expression for the two $r$-matrices we can take, is of type $f(\lambda_1, \lambda_2)c_{12} + g(\lambda_1, \lambda_2)d_{12}$. Comparing with the raw formula of the Poisson brackets, we deduce the loop part of (17) and (18)

\[ r_{12} = f(\lambda_1, \lambda_2)c_{12} + g(\lambda_1, \lambda_2)d_{12} \quad \text{and} \quad s_{12} = f(\lambda_1, \lambda_2)c_{12} - g(\lambda_2, \lambda_1)d_{12} \quad (42) \]

with

\[ f(\lambda_1, \lambda_2) = \frac{1}{2} \frac{(1 - \lambda_1^2)(1 - \lambda_2^2)}{\lambda_1^2 - \lambda_2^2} \quad \text{and} \quad g(\lambda_1, \lambda_2) = \frac{1}{2} \frac{\lambda_1 \lambda_2^{-1}(1 - \lambda_2^2)}{\lambda_1^2 - \lambda_2^2} \]

These rational functions verify some non-trivial algebraic relations that are helpful when dealing with Jacobi identity

\[ g(\lambda_1, \lambda_3)g(\lambda_3, \lambda_2) + f(\lambda_2, \lambda_3)g(\lambda_1, \lambda_2) + f(\lambda_3, \lambda_1)g(\lambda_1, \lambda_2) = 0 \]

\[ g(\lambda_1, \lambda_2)g(\lambda_3, \lambda_2) - f(\lambda_2, \lambda_3)g(\lambda_1, \lambda_3) - f(\lambda_1, \lambda_2)g(\lambda_1, \lambda_3) = 0 \]

\[ g(\lambda_1, \lambda_2)g(\lambda_1, \lambda_3) - f(\lambda_1, \lambda_3)g(\lambda_2, \lambda_3) - f(\lambda_1, \lambda_2)g(\lambda_2, \lambda_3) = (\lambda_2 - \lambda_2^{-1})(\lambda_3 - \lambda_3^{-1}) \quad (43) \]

Now we have to add the central extension (which impose to choose a convention for the previous equations). We can easily see that we need also to introduce the Virasoro algebra. The only possible and non-trivial terms are $E_+ \otimes k$ and $k \otimes E_+$. The goal we want to reach is to include all terms whose variables are different from the dilaton and its spatial derivative, into the two commutators $[r_{12}^f, A_1(x)] + [s_{12}^f, A_2(x)]$. The first miracle is that it can be achieved. Thus, we fix one part of the $r$-matrices on the Virasoro algebra (remember that $k$ is in the center of the algebra, so
Thus, our problem is entirely expressed in terms of eq.(21):

Here we will give some hints for the proof of the Jacobi identity. First of all, let recall the expression for the ultralocal and the non-ultralocal part simultaneously.

We see this formula works due to non-trivial cancelations. In one sense, it’s a proof of the validity of our calculation and a hint of deeper algebraic structure of the problem.

\section*{Appendix B:}

Here we will give some hints for the proof of the Jacobi identity. First of all, let recall the expression of eq.(21):

\[
\{A_1(x), \{A_2(y), A_3(z)\}\} + \text{perm.} = \rho^{-2}(x)\delta(x-y)\delta(y-z) \left([A_1(x), A_{123}] + \text{perm.}\right)
\]

\[+ \left(\partial_x \rho^{-2}\right)\delta(x-y)\delta(y-z) \left(B_{123} + \text{perm.}\right)
\]

\[+ \rho^{-3}(x)\delta(x-y)\delta(y-z) \left([\Phi_1(x), C_{123}] + \text{perm.}\right)
\]

\[+ \rho^{-2}(x)\delta(y-z)\partial_x \delta(x-y) \left(D_{123} + \text{perm.}\right)
\]

with the following values for the coefficients

\[
A_{123} = \left[ r_{12}^{e_1}, r_{23}^{e_2}, r_{31}^{e_3} \right] + \left[ s_{23}^{e_2}, s_{31}^{e_3}, r_{12}^{e_1} \right] - \frac{1}{2} k_2 s_{31}^{e_3} - \frac{1}{2} k_3 r_{12}^{e_1} - \frac{1}{4} [U_{23}, c_{12}]
\]

\[
B_{123} = \left[ s_{23}^{e_2}, s_{31}^{e_3}, r_{12}^{e_1} \right] - \left[ r_{23}^{e_2}, r_{12}^{e_1}, s_{31}^{e_3} \right] + \frac{1}{2} [r_{23}^{e_2}, s_{12}^{e_1}] - \frac{1}{2} [s_{23}^{e_2}, r_{12}^{e_1}] - \frac{1}{4} [U_{23}, c_{12}]
\]

\[
C_{123} = \frac{1}{4} [r_{23}^{e_2}, U_{12}] + \frac{1}{4} [s_{23}^{e_2}, U_{31}] + \frac{1}{8} k_3 U_{12} - \frac{1}{8} k_2 U_{13}
\]

\[
D_{123} = \left[ s_{23}^{e_2}, s_{31}^{e_3}, \right] - \left[ r_{23}^{e_2}, r_{12}^{e_1}, \right] + \left[ s_{23}^{e_2}, s_{12}^{e_1}, \right] - \left[ s_{23}^{e_2}, r_{31}^{e_3} \right] - \frac{1}{4} [U_{23}, c_{12}]
\]

\[
+ \frac{1}{4} k_3 (s_{12}^{e_1} - r_{12}^{e_1}) - \frac{1}{4} k_2 (s_{31}^{e_3} - r_{31}^{e_3}) + \frac{1}{4} k_1 (s_{23}^{e_2} + r_{23}^{e_2})
\]

To obtain this expression, we need Poisson brackets of connection with the constraint \(\Phi\) and the dilaton (see eq.(31) and (26)).

Showing Jacobi identity with (21) is not obvious, because the three \(\delta \partial \delta\) distributions and \(\delta \delta\) are not linearly independent. So, we have to express one of \(\delta \partial \delta\) with respect to the other distributions. It leads to the following formula:

\[
\{A_1(x), \{A_2(y), A_3(z)\}\} + \text{perm.} = \rho^{-2}(x)\delta(x-y)\delta(y-z) \left([A_1(x), A_{123}] + \text{perm.}\right)
\]

\[+ \left(\partial_x \rho^{-2}\right)\delta(x-y)\delta(y-z) \left(B_{123} + \text{perm.}\right)
\]

\[+ \rho^{-3}(x)\delta(x-y)\delta(y-z) \left([\Phi_1(x), C_{123}] + \text{perm.}\right)
\]

\[+ \rho^{-2}(x)\delta(y-z)\partial_x \delta(x-y) \left(D_{123} - D_{123}\right)
\]

It can be easily shown that we have the relations

\[
B_{123} + B_{231} + B_{312} - 2D_{123} = A_{231} + A_{312} - A_{123}
\]

\[
D_{123} - D_{231} = A_{123} - A_{231}
\]

\[
D_{123} - D_{312} = A_{123} - A_{312}
\]

Thus, our problem is entirely expressed in terms of \(A_{123}\) and \(C_{123}\). As announced previously, these coefficients are invariant under cyclic permutations and equal to zero:

\[
A_{123} = A_{231} = A_{312} = 0 \quad \text{and} \quad C_{123} = C_{231} = C_{312} = 0
\]
If the calculations for the $C$ coefficients are rather easy, those for the $A$ ones are more tedious. In particular, when dealing with terms of type $k \otimes d$, the choice of the convention has to be coherent. Another point is the fundamental Poisson brackets are not to be taken on the constraint surface. Else the $[U, c]$ term disappears, and the equation for $A$ on the loop part of the algebra is no longer verified.
References
