Abstract

A scenario based on the TopFlavor model is presented to explain the origin of a light sterile neutrino as indicated by all combined neutrino oscillation experiments. The model is phenomenologically well motivated and compatible with all available low-energy data. The derived neutrino mass matrix can qualitatively explain the observed hierarchy in the neutrino mass splittings as indicated by the neutrino oscillation data. Numerical results are obtained for special cases.

PACS numbers: 14.60Pq
I Introduction

Hints of new physics have recently been advocated through the neutrino sector. The recent observation by the Super-Kamiokande Collaboration of the atmospheric zenith angle dependent deficit \[1\] has strengthened this conclusion. Also the long term puzzle of the solar neutrino deficit \[2\] has been a strong demonstration on the existence of new physics. Recent results on neutrino oscillation have been also reported by the Liquid Scintillation Neutrino Detector (LSND) experiment \[3\]. The observed anomalies in the neutrino data can be naturally understood in terms of massive neutrino oscillations.

The theoretical picture for neutrino oscillation poses a real challenge in understanding the form of the lepton mass matrix as derived from the neutrino oscillation data. A definite picture is obscure due to the large number of free parameters in the neutrino and charged lepton mass matrices. The phenomenological solution is not unique and clearly the need for more data and theoretical breakthrough is essential.

Neutrino oscillation can explain both the solar and atmospheric data in terms of three-generation neutrinos \[4\] (ignoring the LSND results \[3\].) In the simplest explanation picture, the solar neutrino data can be understood in terms of $\nu_e \leftrightarrow \nu_\mu$ oscillation with a small mass splitting not to influence atmospheric data. On the other hand, atmospheric data can be explained in terms of $\nu_\mu \leftrightarrow \nu_\tau$ large mixing with a large mass splitting compared to the solar case \[9\]. However, if we combine the LSND result with the solar and atmospheric data then we have to include at least an extra light neutrino. The full oscillation data requires the existence of three different scales of neutrino mass-squared differences. The different scales can be accommodated only if at least a light fourth neutrino exists. Such a light neutrino has to be sterile, i.e., to decouple from the low-energy observables as indicated by the low-energy experiments \[5\]. Some recent phenomenological studies indicate that in the minimal scheme the dominant transition of solar neutrinos is due to $\nu_e \leftrightarrow \nu_s$ mixing, while the dominant transition of atmospheric neutrinos in long-baseline (LBL) experiments is due to $\nu_\mu \leftrightarrow \nu_\tau$ mixing \[6\].
The inclusion of a sterile neutrino still poses another theoretical challenge. Namely, to understand both the origin of the sterile fermion and the very low mass it has. The small mass is probably the most difficult issue in introducing such a particle. Any successful scenario has to explain the tiny mass of the sterile neutrino in a natural way. A possible scenario would be to generate the light mass through radiative corrections [7]. Another interesting scenario would be to postulate that the extra neutrino is active at a relatively high-energy scale. At that scale the extra neutrino is massless as the assumed dynamics, due to some symmetry, forbids its mass generation. Once the high-energy symmetry is broken (probably in the TeV region), a Dirac mass can be generated while the neutrino decouples from the low-energy regime, i.e., becomes a sterile. Finally, by invoking the seesaw mechanism we can understand the highly suppressed Majorana mass of such a sterile neutrino.

In this work we consider the possibility of understanding the origin of a light sterile neutrino through the second scenario. A similar model has been discussed in Ref. [8], however, the model suffers from theoretical anomalies. Furthermore, an explicit formulation of the model is highly complicated. The model we discuss in this work does not suffer from theoretical drawbacks. It is based on the gauge nonuniversal symmetry $SU(3)_c \times SU(2)_l \times SU(2)_h \times U(1)_Y$ discussed extensively in Refs. [9, 10]. We refer to this model as the TopFlavor model which is anomaly free and phenomenologically well motivated. Several recent phenomenological studies have been published in the literature [10]. To account for the existence of the sterile neutrino, we modify the standard fermion content by the inclusion of few extra fermions. The extra fermion spectrum does not appreciably affect the low-energy regime because of the heavy mass of the extra active fermions, as discussed later. Only one-neutral fermion emerges with a small mass while decouples from the low-energy regime which we then call the sterile neutrino.

The rest of this paper is organized as follows. In Sec. II, we briefly review the model. In Sec. III, we enlarge the fermion spectrum by introducing extra fermions and discuss the mechanism for generating the mass of the sterile and active fermions.
Finally, in Sec. IV we provide some numerical discussion of the model.

II Structure of the Model

The TopFlavor model \cite{9, 10} is based on the gauge symmetry $G = SU(3)_c \times SU(2)_l \times SU(2)_h \times U(1)_Y$. In this model, the third generation of fermions (top quark $t$, bottom quark $b$, tau lepton $\tau$, and its neutrino $\nu_\tau$) is subjected to a new gauge interaction at the high energy scale, instead of the usual weak interaction advocated by the standard model (SM) of the electroweak interaction. On the contrary, the first and second generations only feel the weak interaction supposedly equivalent to the SM case. The new gauge dynamics is attributed to the $SU(2)_h$ symmetry under which the left-handed fermions of the third generation transform in the fundamental representation (doublets), while they remain to be singlets under the $SU(2)_l$ symmetry. On the other hand, the left-handed fermions of the first and second generation transform as doublets under the $SU(2)_l$ group and singlets under the $SU(2)_h$ group. The $U(1)_Y$ group is the SM hypercharge group. The right-handed fermions only transform under the $U(1)_Y$ group as assigned by the SM. Finally, the QCD interactions and the color symmetry $SU(3)_c$ are the same as that in the SM.

The spontaneous symmetry-breaking of the group $G = SU(3)_c \times SU(2)_l \times SU(2)_h \times U(1)_Y$ is accomplished by introducing the complex scalar fields $\Sigma, \Phi_1, \Phi_2$, where $\Sigma \sim (1, 2, 2, 0), \Phi_1 \sim (1, 2, 1, 1),$ and $\Phi_2 \sim (1, 1, 2, 1)$. For the $\Sigma$ field we explicitly write

$$\Sigma = \begin{pmatrix} \pi_1^0 \\ \pi_2^+ \\ \pi_1^+ \\ \pi_2^0 \end{pmatrix},$$

where all scalar fields are complex. The group $G$ is then broken in three different stages. The first stage of symmetry breaking is accomplished once the $\Sigma$ field acquires a vacuum expectation value (vev) $u$, i.e., $\langle \Sigma \rangle = \begin{pmatrix} u & 0 \\ 0 & u \end{pmatrix}$, where $u$ is taken to be real. The form of $\langle \Sigma \rangle$ guarantees the breakdown of $SU(2)_l \times SU(2)_h \rightarrow SU(2)$. Therefore, the unbroken symmetry is essentially the SM gauge symmetry $SU(3)_c \times SU(2)_w \times U(1)_Y$, where $SU(2)_w$ is the usual SM weak group. At this stage, three of the gauge bosons acquire a mass of the order $u$, while the other gauge bosons
remain massless. The phenomenology of the model imposes the constraint $u \gtrsim 1$ TeV. The second and third stage of symmetry breaking (the electroweak symmetry-breaking) is accomplished through the scalar fields $\Phi_1$ and $\Phi_2$ by acquiring their vacuum expectation values $\langle \Phi_1 \rangle = \left( \begin{array}{c} 0 \\ v_1 \end{array} \right)$, and $\langle \Phi_2 \rangle = \left( \begin{array}{c} 0 \\ v_2 \end{array} \right)$, respectively. The electroweak symmetry-breaking scale $v$ is defined $v \equiv \sqrt{v_1^2 + v_2^2} = 246$ GeV. Since the third generation of fermions is heavier than the first two generations, it is suggestive to conclude that $v_2 \gg v_1$. The surviving symmetry at low energy is $SU(3)_c \times U(1)_{em}$ gauge symmetry. Because of this pattern of symmetry breaking, the gauge couplings $g_l$, $g_h$, and $g_Y$ of $SU(2)_l$, $SU(2)_h$, and $U(1)_Y$, respectively, are related to the $U(1)_{em}$ gauge coupling $e$ by the relation $1/e^2 = 1/g_l^2 + 1/g_h^2 + 1/g_Y^2$. We define

$$
\begin{align*}
g_l &= \frac{e}{\sin \theta \cos \phi}, \\
g_h &= \frac{e}{\sin \theta \sin \phi}, \\
g_Y &= \frac{e}{\cos \theta},
\end{align*}$$

where $\theta$ is the usual weak mixing angle and $\phi$ is a new parameter of the model.

For $g_h > g_l$ (equivalently $\tan \phi < 1$), we require $g_h^2 \leq 4\pi$ (which implies $\sin^2 \phi \geq g^2/(4\pi) \approx 0.04$) so that the perturbation theory is valid. Similarly, for $g_h < g_l$, we require $\sin^2 \phi \leq 0.96$. For simplicity, we focus on the region where $x \equiv u^2/v^2 \gg 1$, and ignore the corrections which are suppressed by higher powers of $1/x$. The light gauge boson masses are found to be $M_{W^\pm}^2 = M_Z^2 \cos^2 \theta = M_0^2 (1 + O(1/x))$, where $M_0 \equiv ev/2 \sin \theta$. While for the heavy gauge bosons $W'^\pm$ and $Z'$, one finds

$$
M_{W'^\pm}^2 = M_{Z'}^2 = M_0^2 \left( \frac{x}{\sin^2 \phi \cos^2 \phi} + O(1) \right).
$$

Up to this order, the heavy gauge bosons are degenerate in mass because they do not mix with the hypercharge gauge boson field. The SM fermions acquire their masses through their Yukawa interaction via the $\Phi_1$ and $\Phi_2$ scalar fields. For instance, the leptonic Yukawa sector is given by

$$
\mathcal{L}_{\text{Yukawa}}^\ell = \bar{\Psi}_L^\ell \Phi_1 \left[ g_{11}^\ell e_R + g_{12}^\ell \mu_R + g_{13}^\ell \tau_R \right] + \\
\bar{\Psi}_L^\ell \Phi_2 \left[ g_{21}^\ell e_R + g_{22}^\ell \mu_R + g_{23}^\ell \tau_R \right] + \\
\bar{\Psi}_L^\ell \Phi_2 \left[ g_{31}^\ell e_R + g_{32}^\ell \mu_R + g_{33}^\ell \tau_R \right] + h.c.,
$$

where
where
\[ \Psi_1^L = \left( \frac{\nu_{eL}}{e_L} \right), \quad \Psi_2^L = \left( \frac{\nu_{\mu L}}{\mu_L} \right), \quad \text{and} \quad \Psi_3^L = \left( \frac{\nu_{\tau L}}{\tau_L} \right). \]  

(5)

The phenomenology of the model has been studied extensively in Refs. \cite{9,10}. Comparisons with the Large Electron Positron (LEP) and other low-energy data have been investigated and constraints on the heavy gauge bosons mass are reported as \( M_{W'} \gtrsim 1 \text{ TeV} \). The parameter \( x \equiv u^2/v^2 \) is constrained by LEP data to be larger than 20. Other low-energy data such as the \( \tau \) life time imposes a higher constraint on \( x \) for specific scenarios of lepton mixing. Flavor changing neutral current (FCNC) effects in the lepton and quark sectors have been explored and contributions to different processes have been calculated \cite{10}. Therefore, in this work we only concentrate on the leptonic mass matrix and refer the reader to Refs. \cite{9,10} for a detailed study of the phenomenology of the model.

**III Extra Fermions**

To explain the existence of the light sterile neutrino in our scenario we enlarge the particle spectrum by the inclusion of extra fermions. We consider the minimal number of particles needed to account for the existence of the light sterile neutrino and without introducing anomalies in the structure of the model. Furthermore, consistency with low-energy data should be maintained and therefore the extra active fermions should decouple from the low-energy regime.

At the high-energy scale the gauge symmetry is assumed to be \( G = SU(3)_c \times SU(2)_l \times SU(2)_h \times U(1)_Y \). At a lower scale, \( \langle \Sigma \rangle \sim \) a few TeV, the gauge symmetry is broken into the SM symmetry group \( H_1 = SU(3)_c \times SU(2)_w \times U(1)_Y \). At the electroweak scale the final stage of symmetry breaking occurs and the surviving symmetry group is \( H_2 = SU(3)_c \times U(1)_{em} \). The fermion spectrum includes the standard three fermion generations with the transformation, under \( G \), as explained in Sec. II.

We enlarge the fermion spectrum by the inclusion of three sets of extra fermions as follow:

\(^2\)Although some differences in the scalar sector exist among those references.
a) To explain the extremely light neutrino masses we invoke the seesaw mechanism. Therefore, four right-handed neutrinos are introduced, $\nu_e R$, $\nu_\mu R$, $\nu_\tau R$, and $\nu_s R$. The four right-handed neutrinos are singlets under $G$ and are assumed to be Majorana fermions with masses of the order of the Grand Unified Theory (GUT) scale.

b) We introduce a bi-doublet fermion field $S_L$ with the transformation $S_L \sim (1, 2, 2, 0)$. Explicitly, $S_L = \nu_s L + S^a_L \tau^a$ transforms, under $G$, as

$$S_L \rightarrow g_1 S_L g_2^\dagger,$$  

(6)

where $g_1 \in SU(2)_l$ and $g_2 \in SU(2)_h$. Once the symmetry group $G$ is broken down into the symmetry group $H_1$, the field $S_L$ decomposes into two parts, with transformation under $H_1$ as $(1, 3, 0) + (1, 1, 0)$. The neutral field with the transformation $(1, 1, 0)$ corresponds to the sterile neutrino. The triplet field remains an active and thus must acquire a heavy Dirac mass in order to be consistent with the low-energy data \cite{5}. To prevent the uncontrolled Majorana mass we assume that $S_L$ carries a conserved quantum number $z_L$ at the high-energy scale. The new quantum number is due to a global $U(1)$ symmetry which causes no harmful anomaly to spoil the foundation of the model \cite{11}.

c) We introduce another triplet fermion field $S_R = S^a_R \tau^a$ with the transformation, under $G$, as $(1, 1, 3, 0)$ just for the purpose of giving a Dirac mass to the active triplet field of $S_L$. Similar to $S_L$, the field $S_R$ is assumed to carry a quantum number $z_R$ to prevent the dangerous Majorana mass term. Hence, a Dirac mass for the extra active fermions is generated through the Yukawa interaction term

$$\mathcal{L}_a = \frac{g_a}{2} \text{Tr} \left[ S^a_L \Sigma S^a_R \right],$$  

(7)

where $g_a \sim 1$ is a Yukawa coupling. Once the scalar field $\Sigma$ acquires its vev $u \gtrsim 1$ TeV, a Dirac mass for the triplet fermions is generated, $m_a = g_a u \gtrsim 1$ TeV. In order for the Yukawa term in Eq. (7) to conserve the assumed global $U(1)$ symmetry, we require $\Sigma$ to carry a quantum number $z_0$ such that $z_L = z_R + z_0$. 
The sterile neutrino $\nu_{sL}$ acquires its Dirac mass through the Yukawa term

$$\mathcal{L}_s = \frac{g_s}{2} \text{Tr} \left[ S_L \tau_2 \Sigma^* \tau_2 \right] \nu_{sR},$$

where $g_s \sim 1$ is a Yukawa coupling. The Yukawa terms in Eqs. (8) conserve the new quantum number provided that we demand $z_L = -z_0 = z_R/2$. It is important to notice that the form of $\Sigma$ is as given in Eq. (1). A simple choice would be

$$\Sigma = \pi^0 + i\pi^a \tau_a = \left( \frac{\pi^0 + i\pi^3}{\sqrt{2}} \right),$$

(9)

where $\pi^0$ and $\pi^a$ are taken to be real fields. However, for this particular choice $\tau_2 \Sigma^* \tau_2 = \Sigma$ and therefore, the Yukawa terms in Eqs. (7,8) are not simultaneously invariant under the assumed global $U(1)$ symmetry. To conclude, the extra fields we introduce are the minimal number of fields required to account for the existence of a light sterile neutrino without spoiling the accuracy of the low-energy data, and also without introducing any theoretical anomalies into the model.

The full neutrino Yukawa interaction terms are given as

$$\mathcal{L}_{\nu \text{Yukawa}} = \overline{\Psi}_L \Phi^* \left[ g_{11}^\nu \nu_{eR} + g_{12}^\nu \nu_{\mu R} + g_{13}^\nu \nu_{\tau R} + g_{14}^\nu \nu_{sR} \right] + \overline{\Psi}_R \Phi^* \left[ g_{21}^\nu \nu_{eR} + g_{22}^\nu \nu_{\mu R} + g_{23}^\nu \nu_{\tau R} + g_{24}^\nu \nu_{sR} \right] + \overline{\Psi}_L \Phi^* \left[ g_{31}^\nu \nu_{eR} + g_{32}^\nu \nu_{\mu R} + g_{33}^\nu \nu_{\tau R} + g_{34}^\nu \nu_{sR} \right] + \frac{1}{2} \text{Tr} \left[ S_L \tau_2 \Sigma^* \tau_2 \right] \left[ g_{41}^\nu \nu_{eR} + g_{42}^\nu \nu_{\mu R} + g_{43}^\nu \nu_{\tau R} + g_{44}^\nu \nu_{sR} \right] + h.c.,$$

(10)

where $\Phi_{1,2} \equiv i\tau_2 \Phi^*_{1,2}$. The Dirac mass matrix derived from Eq. (10) is written as

$$M_D = \begin{pmatrix}
g_{11}^\nu v_1 & g_{12}^\nu v_1 & g_{13}^\nu v_1 & g_{14}^\nu v_1 
g_{21}^\nu v_1 & g_{22}^\nu v_1 & g_{23}^\nu v_1 & g_{24}^\nu v_1 
g_{31}^\nu v_2 & g_{32}^\nu v_2 & g_{33}^\nu v_2 & g_{34}^\nu v_2 
g_{41}^\nu u & g_{42}^\nu u & g_{43}^\nu u & g_{44}^\nu u
\end{pmatrix},$$

(11)

The right-handed neutrino Majorana mass matrix $M_R$ is assumed to have a common mass scale of the order of the GUT scale, $M_X \sim 10^{15}$ GeV. Therefore, the full neutrino mass matrix forms a $8 \times 8$ matrix which can be written as

$$M_\nu = \begin{pmatrix}
0 & M_D \\ M_D^T & M_R
\end{pmatrix}.$$
By invoking the seesaw mechanism the left-handed neutrino Majorana mass matrix is then given as

\[ M_L = M_D M_R^{-1} M_D^T. \]  

(13)

Due to the seesaw mechanism all elements of \( M_L \) are highly suppressed by the GUT scale \( M_X \) of the right-handed Majorana mass matrix \( M_R \). Therefore, we can introduce the sterile neutrino with a natural mechanism for generating its light mass as required by the neutrino oscillation data. In the next section we give further discussion of the derived neutrino mass matrix.

**IV Discussion and Conclusions**

The mass matrix in Eq. (11) is written in its most general form. A quantitative analysis is attainable only if the structure of the mass matrix is fully determined which requires further theoretical assumptions to be incorporated in the structure of the model. Nevertheless, the structure of the mass matrix already suggests an interesting behavior. There are three hierarchical energy scales in the mass matrix \( M_D \), namely, \( u \gg v_2 \gg v_1 \) which could be connected to the observed three hierarchical mass scales in the neutrino data, namely, \( \Delta m_{\text{LSND}}^2 \gg \Delta m_{\text{atm}}^2 \gg \Delta m_{\text{solar}}^2 \). It is suggestive to conclude that

\[
\Delta m_{\text{LSND}}^2 \sim \left( \frac{u^2}{M_X} \right)^2 \approx 1 \text{ eV}^2, \\
\Delta m_{\text{atm.}}^2 \sim \left( \frac{v_2^2}{M_X} \right)^2 \approx 10^{-3} \text{ eV}^2, \\
\Delta m_{\text{solar}}^2 \sim \left( \frac{v_1^2}{M_X} \right)^2 \approx 10^{-5} \text{ eV}^2, 
\]  

(14)

as indicated by the neutrino oscillation data [1, 2, 3, 4]. In fact from the LEP data, we already know that \( u \gtrsim v \sqrt{20} \approx 1.2 \text{ TeV} \) [10]. The observed mass scales can be obtained if we simply choose \( u \approx 1.2 \text{ TeV} \) and \( v_2 \approx 230 \text{ GeV} \). From which we conclude that \( v_1 \approx 75 \text{ GeV} \), \( M_X \approx (1 - 10) \times 10^{15} \text{ GeV} \), and

\[
\frac{\Delta m_{\text{LSND}}^2}{\Delta m_{\text{atm.}}^2} \sim \frac{u^4}{v_2^4} \approx 10^{+3},
\]
In the simplest scheme where oscillation data can be explained in terms of two flavor mixing, it has been argued that the dominant transition of solar neutrino is due to $\nu_e \leftrightarrow \nu_s$ mixing \[6\]. Such a picture can hardly be satisfied by our model with the above choice of parameters and without the need for fine tuning. In the case of $\nu_e \leftrightarrow \nu_s$ mixing one can show that the effective $2 \times 2$ mass matrix is given as

$$ M_L = \frac{1}{M_X} \begin{pmatrix} g_1 v_1^2 & g_2 v_1 u \\ g_2 v_1 u & g_3 u^2 \end{pmatrix}, \quad (16) $$

where the couplings $g_{1,2,3} \sim 1$. Therefore, one can show that the solar mass splitting is given as $\Delta m_{solar}^2 \approx u^4/M_X^2$ which is many orders of magnitude larger than the experimental fit \[2, 4\]. If we take $M_X$ to be of order $10^{18}$ GeV, which is close to the Planck scale, we get a result consistent with the experimental fit as shown in Table 1, where we consider the numerical values $u = 1200$ GeV, $M_X = 10^{18}$ GeV, and $v_1 = 75$ GeV. In Table 1, the numerical values of the Yukawa couplings as well as their solar neutrino solution are given. However, such a solution is not favored as we can not explain the apparent hierarchy among the solar, atmospheric, and LSND data.

In conclusion we have provided a scenario based on the TopFlavor model to explain the existence of a light sterile neutrino. The scenario is anomaly free and phenomenologically compatible with all existing low-energy data. The scenario can also qualitatively explain the hierarchy in the observed mass scales of the neutrino oscillation data. Quantitative results are obtained for special cases.
