Abstract

In this paper we recalculate the two-loop beta-function coefficients in the two-dimensional Sine-Gordon (SG) model in a two-parameter perturbative expansion around the asymptotically free (AF) point. The study of the SG model in the vicinity of this point is especially important since this region is used in the description of the Kosterlitz-Thouless phase transition in the two-dimensional $O(2)$ nonlinear $\sigma$-model, better known as the XY model\(^1\). This was the motivation of the authors of [2], who have undertaken a systematic study of perturbation theory in a two-parameter expansion around the AF point. They calculated the renormalization group beta-functions up to the two-loop coefficients. The beta-function coefficients were also calculated in [3] by a completely different technique based on string theory. The results found in [3] differ from those of [2] at the two-loop level. The question of two-loop beta-function coefficients were considered also in [4] for a class of generalized Sine-Gordon models. The results, when specialised to the case of the ordinary SG model, agree with those of [3], but disagree with those of [2]. This is the reason why, it seems, it is generally excepted in the literature [5] that the two-loop beta-function coefficients are correctly given by [3] and that Amit et al. [2] must have made a mistake.

The purpose of the present paper is to show that, in fact, the two-loop results of Amit et al. are correct. We show this first by comparing the SG beta-function to known results in the chiral Gross-Neveu model [6], which is known to be equivalent to the SG model at its AF point. We also check the beta-function coefficients by considering the renormalization of $2n$-point functions of exponentials of the SG field.

Following [2] we consider the Euclidean Lagrangian

$$\mathcal{L} = \frac{1}{2} \partial_\mu \phi \partial_\mu \phi + \frac{m_0^2}{2} \phi^2 + \frac{\alpha_0}{\beta_0^2 a^2} [1 - \cos(\beta_0 \phi)],$$

where $m_0$ is an IR regulator mass and $a$ is the UV cutoff (of dimension length). UV regularized correlation functions are calculated by using

$$G_0(x) = \frac{1}{2\pi} K_0 \left( m_0 \sqrt{x^2 + a^2} \right),$$

where $K_0$ is the modified Bessel function, as the $\phi$ propagator. Our strategy is slightly different from [2], who really considered the renormalization of the massive SG model (1) of mass $m_0$. We treat $m_0$ as an IR regulator mass and consider IR stable physical quantities for which we can take the limit $m_0 \to 0$ already at the UV regularized level (before UV renormalization).

The model (1) is renormalizable in a two-parameter perturbative expansion around the point corresponding to the couplings $\alpha_0 = 0, \beta_0^2 = 8\pi$. Writing

$$\beta_0^2 = 8\pi (1 + \delta_0)$$

\(^1\)For a review of the Sine-Gordon description of the Kosterlitz-Thouless theory, see [1]
the two bare expansion parameters are $\alpha_0$ and $\delta_0$ and physical quantities can be made UV finite by the renormalizations

$$\begin{align*}
\alpha_0 &= Z_\alpha \alpha; \quad Z_\alpha = 1 + g_1\delta \ell + \alpha^2(\bar{g}_2\ell^2 + g_2\ell) + \delta^2(\bar{g}_3\ell^2 + g_3\ell) + \ldots, \\
1 + \delta_0 &= Z_\phi^{-1}(1 + \delta); \quad Z_\phi = 1 + f_1\alpha^2\ell + \alpha^2\delta(\bar{J}_2\ell^2 + f_2\ell) + \ldots,
\end{align*}$$

(4)

(5)

where $\alpha$ and $\delta$ are the renormalized couplings and $\ell = \ln \mu a$ with $\mu$ an arbitrary renormalization point. The dots stand for terms higher order in perturbation theory and the numerical coefficients $g_1, f_1$ etc. can be calculated by renormalizing correlation functions. The results of Amit et al. are

$$f_1 = \frac{1}{32}, \quad g_1 = -2, \quad f_2 = -\frac{3}{32}, \quad g_2 = -\frac{5}{64}, \quad g_3 = 0,$$

(6)

whereas those of [3] and [4] are

$$f_1 = \frac{1}{32}, \quad g_1 = -2, \quad f_2 = -\frac{1}{32}, \quad g_2 = -\frac{1}{32}, \quad g_3 = 0.$$

(7)

We see that the one-loop coefficients are the same but not all two-loop coefficients agree. The subject of this paper is to recalculate these numbers.

The renormalization group (RG) beta-functions can be calculated by solving the equations

$$D\alpha = D\delta = 0,$$

(8)

where, as usual, the RG operator is defined by

$$D = -a \frac{\partial}{\partial a} + \beta_\alpha(\alpha_0, \delta_0) \frac{\partial}{\partial \alpha_0} + \beta_\delta(\alpha_0, \delta_0) \frac{\partial}{\partial \delta_0}.$$  

(9)

One finds

$$\begin{align*}
\beta_\alpha &= -g_1\alpha_0\delta_0 - g_2\alpha_0^3 - g_3\alpha_0\delta_0^2 + \ldots, \\
\beta_\delta &= f_1\alpha_0^2 + (f_1 + f_2)\alpha_0^2\delta_0 + \ldots
\end{align*}$$

(10)

(11)

It is well-known that, in the case of several couplings, the higher beta-function coefficients are not all scheme independent. Indeed, considering the perturbative redefinitions

$$\tilde{\alpha}_0 = \alpha_0 + c_1\alpha_0\delta_0 + \ldots \quad \tilde{\delta}_0 = \delta_0 + c_2\alpha_0^2 + \ldots$$

(12)

one finds that in addition to the one loop coefficients $f_1$ and $g_1$ only the following two two-loop coefficient combinations are invariant.

$$g_3, \quad J = 2g_2 - f_2.$$  

(13)
The RG analysis with two couplings can be made similar to the case of a single coupling by changing the variables from $\alpha_0$ and $\delta_0$ to the pair $Q$ and $\delta_0$, where $Q$ is a RG invariant (solution of the $\mathcal{D}Q = 0$ equation), given in perturbation theory by

$$Q = f_1 \alpha_0^2 + g_1 \delta_0^2 + 2g_2 \alpha_0^2 \delta_0 + F_2 \delta_0^3 + \ldots,$$

where $F_2 = \frac{2}{3}g_3 - \frac{2}{3}g_1 + \frac{2}{3f_1}J$. Now $Q$, being a RG invariant, can almost be treated as if it were a numerical constant and $\delta_0$ as the ‘true’ coupling. The beta-function in these variables is

$$\beta(\delta_0, Q) = Q + 2\delta_0^3 + AQ\delta_0 + B\delta_0^3 + \ldots,$$

where $A = 1 - J/f_1$ and $B = 2(A - g_3)/3$.

It is well-known that the SG model can also be formulated in terms of two fermion fields, interacting with a chirally symmetric current-current interaction [1]. A special case of the two-fermion model corresponds to the $SU(2)$-symmetric chiral Gross-Neveu model. This correspondence is evident in the bootstrap approach, since the SG S-matrix in the limit $\beta_0 \to \sqrt{8\pi}$ becomes the $SU(2)$ chiral Gross-Neveu S-matrix. This asymptotically free model has to correspond to one of the possible RG trajectories in the two-parameter SG language. It is easy to see that it has to be the $Q = 0$ trajectory, since this is the only trajectory going through the origin ($\delta_0 = \alpha_0 = 0$) of the parameter space. More precisely, the chiral Gross-Neveu model must correspond to the negative half of the $Q = 0$ trajectory, which is an UV asymptotically free trajectory. Making the identification

$$\delta_0 = -\frac{1}{\pi} g^2,$$

where $g$ is the coupling of the $SU(2)$ Gross-Neveu model, the Gross-Neveu beta-function becomes

$$\beta(g) = -\frac{1}{\pi} g^3 + \frac{B}{2\pi^2} g^5 + \ldots$$

Using the results of Amit et al., (6), $B = 2$, while $B = 4/3$ if we trust [3] and [4], (7). Comparing (17) to the results of the beta-function calculations performed directly in the fermion language [6] we see that the correct Gross-Neveu beta-function is reproduced if $B = 2$. Thus the two-loop results of Amit et al. are correct after all! This was the observation\(^2\) that served as our motivation for the present study. The correctness of the two-loop Gross-Neveu beta-function coefficient has been checked by studying the system in the presence of an external field [7]. Using this method the value of this coefficient can be read off from the bootstrap S-matrix and the results are in agreement with [6].

\(^2\)We thank P. Forgács who made this observation first and called our attention to it.
We now turn to the explicit calculation of the renormalization parameters (4,5). The first quantity we consider is the two-point function of the $U(1)$ current $J_\mu = \frac{i}{2\pi} \epsilon_{\mu\nu} \partial_\nu \phi$:

$$\langle J_\mu(x) J_\nu(y) \rangle = \int \frac{d^2p}{(2\pi)^2} \left( \frac{p_\mu p_\nu}{p^2} - \delta_{\mu\nu} \right) e^{ip(x-y)} I(p).$$  \hspace{1cm} (18)

The advantage of considering this physical quantity is that it is IR stable. Putting $m_0 = 0$ we find

$$I(p) = \frac{2}{\pi} \left\{ 1 + \delta_0 + \frac{\alpha_0^2}{32} \left( \ln pa + K + \frac{1}{2} \right) + \frac{\alpha_0^2 \delta_0}{16} (\ln pa + K)^2 + \ldots \right\}, \hspace{1cm} (19)$$

where $K = -\Gamma'(1) - 1 - \ln 2$. Since the current is conserved there is no operator renormalization required here and (19) must become finite after the substitutions (4,5). From this requirement we get

$$f_1 = \frac{1}{32}, \quad g_1 = -2, \quad f_2 = -\frac{3}{32}. \hspace{1cm} (20)$$

To determine the remaining two-loop coefficients $g_2$ and $g_3$ we have to calculate $Z_\alpha$, the renormalization constant corresponding to $\alpha_0$. For this purpose we need a quantity with a perturbative series starting at $\mathcal{O}(\alpha_0)$. We have chosen the $2n$-point correlation function

$$X = \langle \mathcal{A}(x_1) \ldots \mathcal{A}(x_{2n}) \rangle, \hspace{1cm} (21)$$

where

$$\mathcal{A}(x) = \left( \frac{1}{a} \right)^\frac{1}{2n} e^{\frac{i\phi_0}{2\pi} \phi(x)}. \hspace{1cm} (22)$$

Although, in contrast to the Noether current, the operator (22) needs to be renormalized, for large enough $n$ the dimension of (22) is so small that there is no operator mixing and the operator renormalization constant can simply be determined from the correlation function

$$Y = \langle \mathcal{A}(x_1) \ldots \mathcal{A}(x_n) \mathcal{A}^*(y_1) \ldots \mathcal{A}^*(y_n) \rangle. \hspace{1cm} (23)$$

A second order calculation gives

$$Y = M \left( \frac{1}{\pi^2} \right) \left\{ 1 + \frac{\delta_0}{n^2} L + \frac{\delta_0^2}{2n^4} L^2 + \frac{\alpha_0^2}{64n^3} L^2 + L \left( \frac{\alpha_0^2}{64n^2} - \frac{\alpha_0^2}{128} \left[ W \left( \frac{1}{n} \right) + W \left( -\frac{1}{n} \right) \right] \right) + \ldots \right\}. \hspace{1cm} (24)$$
where

\[ M = \frac{\prod_{i<j} |x_i - x_j| \prod_{k<l} |y_k - y_l|}{\prod_{i,k} |x_i - y_k|}, \]  

(25)

\[ L = \ln Ma^n \]  

and the dots stand for finite \( O(\alpha_0^2) \) terms as well as higher order terms. \( W(\mu) \) is defined by

\[ W(\mu) = -1 + \int_0^1 dz \, z^\mu F(\mu, \mu; 1; z) + \int_0^1 dz \, z^2 \left[ F(\mu, \mu; 1; z) - 1 - \mu^2 z \right], \]  

(26)

where \( F(\alpha, \beta; \gamma; z) \) is the standard hypergeometric function. (24) can be made finite by the renormalization \( Y_R = Z_{2n} Y \), where

\[ Z_{2n} = 1 - \frac{1}{n} \delta + \frac{1}{2n^2} \ell^2 \delta^2 + \frac{1}{64n} \ell^2 \alpha^2 + k_1 \ell \alpha^2 + \ldots, \]  

(27)

with

\[ k_1 = -\frac{1}{64n} + \frac{n}{128} \left[ W \left( \frac{1}{n} \right) + W \left( -\frac{1}{n} \right) \right]. \]  

(28)

For the \( 2n \)-point function \( X \) a second order calculation gives

\[ X = \frac{\alpha_0}{16\pi} N \left( \frac{1}{n} \right) F \left\{ 1 + \delta_0 \Psi + \frac{1}{2} \delta_0^2 \Psi^2 + \frac{n \alpha_0^2}{128n + 64} \Psi \left[ \Psi + 4 + \frac{1}{n} - nW \left( \frac{1}{n} \right) \right] + \ldots \right\}, \]  

(29)

where

\[ N = \prod_{i<j} |x_i - x_j|, \quad F = \int d^2 z \frac{1}{\prod_i |z - x_i|^2}. \]  

(30)

and

\[ \Psi = -1 + \frac{1}{n^2} \ln \left( Na^{-n(2n-1)} \right) - \frac{2}{nF} \sum_j \int d^2 z \, \ln \left[ \frac{|z - x_j|}{a} \right] \frac{1}{\prod_i |z - x_i|^2}. \]  

(31)

In (29) the dots represent finite terms of \( O(\alpha_0^2) \) and \( O(\delta_0^2) \) as well as higher terms. Renormalizing \( X \) by requiring \( X_R = Z_{2n} X \) to be finite after coupling constant renormalization gives

\[ g_3 = 0 \quad \text{and} \quad g_2 = -\frac{1}{16} + \frac{n}{128} \left[ W \left( \frac{1}{n} \right) - W \left( -\frac{1}{n} \right) \right]. \]  

(32)
At first sight $g_2$ seems to be $n$-dependent which would mean that the $2n$-point function (21) cannot really be made finite with wave function plus coupling constant renormalization. Luckily, however, one can see that using the identity

$$W(\mu) - W(-\mu) = -2\mu$$  \hspace{1cm} (|\mu| < 1)  \hspace{1cm} (33)$$
satisfied by the hypergeometric function, $g_2$ is equal to the $n$-independent constant $-5/64$. Moreover, (32) together with (20) reproduce (6), the results of [2]. The nontrivial cancellation of the $n$-dependence makes us more confident that these are the correct two-loop coefficients.

Acknowledgements
We would like to thank P. Forgács for calling our attention to the fact that the results of [2] reproduce the correct two-loop coefficients for the chiral Gross-Neveu model.
