\[ \frac{df}{d^3q} (x_d \rightarrow b_d \rightarrow b_d + |q|) = \frac{1}{3} \int \frac{d^3q}{(2\pi)^3} \rho (x_d \rightarrow b_d) \left( x_d \rightarrow b_d + |q| \right) \]

In the context of the \(\pi^+\pi^-\) model, the invariant mass distribution is given by
\[ M(x) = \frac{1}{2}(x^2 - m^2 + i\epsilon) \]
and the form factor is
\[ F(q^2) = \frac{1}{(1 + q^2)^{\nu}} \]

\section*{1. Introduction}

In the 1970s, the study of the production of vector mesons in hadron-photon collisions was initiated. The first experiments were performed at the Brookhaven National Laboratory and the Stanford Linear Accelerator Center. The subsequent experiments focused on understanding the dynamics of hadron-photon collisions, particularly the production of vector mesons. The analysis of these experiments provided important insights into the structure of hadrons and the nature of the strong interaction.

\section*{2. Single Inclusive Cross Section}

In the 1980s, the search for \(Z^0\) production in hadron-photon collisions was initiated. The first experiments were performed at the CERN-ISR and the Stanford Linear Accelerator Center. The subsequent experiments focused on understanding the dynamics of hadron-photon collisions, particularly the production of vector mesons. The analysis of these experiments provided important insights into the structure of hadrons and the nature of the strong interaction.
\[ T_{ij} = Z_c^{-1/2} \left( \phi_i(y) \right) \langle X(p_X) \rangle \left( \phi_j(z) \right) \delta(y-z) \] (3)

The single-particle inclusive cross section \( f_{inc}(p_3) \) is defined by

\[ f_{inc}(p_3) := \int \frac{d^3 \pi}{d^3 p_3} (a + b \rightarrow c + X) \] (4)

In the usual way the sum over all states \( \left( a + b \rightarrow c + X \right) \) in (4) can be carried out using completeness and translational invariance

\[ f_{inc}(p_3) = \frac{1}{4(2\pi)^3} \int d^3 x \ e^{i p \cdot x} \] (5)

Rewrite \( f_{inc}(p_3) \) to get time-ordered operators

\[ f_{inc}(p_3) = \int \frac{d^3 \pi}{d^3 p_3} \text{Im} \mathcal{C}(p_1, p_2, p_3), \] (6)

\[ \mathcal{C}(p_1, p_2, p_3) = i \int d^3 x \ e^{i p \cdot x} \mathcal{M}(x), \] (7)

\[ \mathcal{M}(x) = Z_c^{-1} \left( \phi_i(y) \right) \left( \phi_j(z) \right) \delta(-x^0) \] (8)

The amplitude \( \mathcal{C}(p_1, p_2, p_3) \) will be written as a field-field correlation function in a forward scattering amplitude, but in a modified effective theory.

3. MODIFIED EFFECTIVE THEORY FOR SCALAR FIELDS

Let us assume that the basic dynamical variables of the original theory are the operators for unrenormalised scalar fields \( \phi_i(x) \) and their conjugate canonical momenta \( \Pi_i(x) \) (\( i = 1, ..., N \)). We denote \( \phi_i(x) \) and \( \Pi_i(x) \) collectively as \( \Phi(x) \). Let \( H \) be the Hamiltonian of the system which we split into a free part \( H_0 \) and an interaction part \( H_I \) which may depend explicitly on the time \( t \), but should not involve time derivatives of \( \Pi_i(x) \)

\[ H(t, \Phi(\vec{x}, t)) = H_0(\Phi(\vec{x}, t)) + H_I(t, \Phi(\vec{x}, t)) \] (9)

with

\[ \lim_{t \to \pm \infty} H(t, \Phi(\vec{x}, t)) = H_0(\Phi(\vec{x}, t)). \] (10)

Besides the interacting fields and momenta \( \Phi \) free fields and momenta \( \Phi^{(0)} \) are considered with the corresponding Hamiltonian \( H_0 \).

We assume now as usual that there exist unitary operators \( U(t) \) that realize the time-dependent canonical transformations relating \( \Phi \) to \( \Phi^{(0)} \)

\[ \Phi(\vec{x}, t) = U^{-1}(t) \Phi^{(0)}(\vec{x}, t) U(t). \] (11)

Taking as boundary condition

\[ \lim_{t \to \pm \infty} \Phi(\vec{x}, t) = \Phi^{(0)}(\vec{x}, t) \] (12)

we get

\[ U(t) = T \exp \left[ -i \int_{-\infty}^{t} dt' H_I(t', \Phi^{(0)}(\vec{x}, t')) \right]. \] (13)

We define furthermore

\[ U(t_2, t_1) = U(t_2) U^{-1}(t_1). \] (14)

so that the S-matrix is given as

\[ S = \lim_{t \to \pm \infty} U(t, -t) \]

\[ = T \exp \left[ -i \int_{-\infty}^{+\infty} dt' H_I(t', \Phi^{(0)}(\vec{x}, t')) \right]. \] (15)

Now we return to the single inclusive cross section, where we have to calculate the matrix element

\[ \mathcal{M}(x) = Z_c^{-1} \left( \phi_i(y) \right) \left( \phi_j(z) \right) \delta(-x^0) \] (16)

\[ \langle a(p_1), b(p_2), \text{in} \left| \phi_i(y) \phi_j(z) \right\rangle \delta(-x^0) \] (17)

\[ \langle a(p_1), b(p_2), \text{in} \left| \phi_i(y) \phi_j(z) \right\rangle \delta(-x^0) \] (18)
Following the time-dependence in $\mathcal{M}(x)$ from the right to the left, we start at time $-T \to -\infty$ and pass through operators of increasing time arguments until time 0. Then the time sequence changes and we go back in time to time $-T' \to -\infty$. In a usual matrix element the time arguments should increase instead. We will now show that we can write the matrix element $\mathcal{M}[\Phi]$ in the usual form, with time increasing from right to left, if we pass to operators $U$ of the form (13) but with a modified interaction Hamiltonian $\hat{H}_1$. As the time-sequence in $\mathcal{M}$ is correct up to $t = 0$, we request

1) $\hat{H}_1(t) = H_1(t, \Phi^{(0)}(\vec{x}, t))$ for $t < 0$
2) $\hat{S} = 1$ \hspace{1cm} (17)

with

$$\hat{S} = \text{Tr} \left[ e^{-i \int_{-\infty}^{+\infty} dt' \hat{H}_1(t', \Phi^{(0)}(\vec{x}, t'))} \right]. \hspace{1cm} (18)$$

It follows

$$\hat{H}_1(t) = \theta (-t) H_1(t, \Phi^{(0)}(\vec{x}, t))$$
$$- \theta (t) H_1(-t, \Phi^{(0)}(\vec{x}, -t)). \hspace{1cm} (19)$$

For $t > 0$ our modified interaction Hamiltonian $\hat{H}_1(t)$ depends on the free fields and momenta at time $(-t)$. But we know how to express the free fields and momenta at time $(-t)$ by their values at time $t$ using the free field equations of motion. Thus, we can consider $\hat{H}_1(t)$ as a nonlocal functional of the dynamical variables $\Phi^{(0)}(\vec{x}, t)$ at the same time $t$ also for $t > 0$

$$\hat{H}_1(t) = \hat{H}_1(t, \Phi^{(0)}(\vec{x}, t)). \hspace{1cm} (20)$$

Therefore, we can consider our matrix element as of the standard type but in the modified theory governed by the total Hamiltonian

$$\hat{H}(t, \Phi(\vec{x}, t)) = \hat{H}_0(\Phi(\vec{x}, t)) + \hat{H}_1(t, \Phi(\vec{x}, t)). \hspace{1cm} (21)$$

Here we denote by $\langle \rangle$ matrix elements in the modified theory

$$\mathcal{M}(x) = Z^{-1} \langle \theta (-x^0) \left( \partial_y + m_{z}^{2} \right) \Phi(x + z) \left| \begin{array}{c} a(p_1), b(p_2), \text{out} \end{array} \right\rangle \right|_{y \rightarrow 0^-, \ z \rightarrow 0^-}. \hspace{1cm} (22)$$

The matrix element $\mathcal{M}$ is written in the standard form with an in-state to the right and an out-state to the left. The prize we have to pay is that we have to use the modified theory where the Hamiltonian $\hat{H}(t)$ has a sudden variation at $t = 0$ and is nonlocal for $t > 0$.

4. INCLUSIVE PRODUCTION IN QED AND AN ABELIAN GLUON MODEL

4.1. QED and the Abelian Gluon Model

In this section inclusive reactions are considered in QED coupled to an abelian gluon model. An example for such a reaction is

$$e^+(p_1) + e^-(p_2) \rightarrow q(p_3) + X. \hspace{1cm} (23)$$

Starting point is the Lagrangian describing the interaction of electrons of mass $m$ and charge $-e$ with a massive photon of mass $\lambda$ - to avoid any infrared divergences - and of two quark flavours of equal mass $M$ and electric charge $eQ_q$ with the photon and a massive abelian gluon of mass $\mu$.

As Lagrangian we choose

$$\mathcal{L} = - \frac{1}{4} G_{\mu\nu} G^{\mu\nu} - \frac{1}{2 g_0} (\partial_\mu G^{\mu})^2 + \frac{1}{2} \mu^2 G_{\mu} G^{\mu}$$
$$- \frac{1}{4} F_{\mu\nu} F^{\mu\nu} - \frac{1}{2 \xi_0} (\partial_\mu A^{\mu})^2 + \frac{1}{2} \lambda^2 A_{\mu} A^{\mu}$$
$$+ \bar{\psi} \left( i \frac{\gamma^\mu \partial_\mu}{2} - m_0 + e_0 A_\mu \right) \psi$$
$$+ \bar{q} \left( i \frac{\gamma^\nu \partial_\nu}{2} - M_q - e_q Q_q A_\nu - g_0 \gamma_5 q \right) q. \hspace{1cm} (24)$$

where $G_{\mu\nu}$ denotes the abelian gluon field and $G^{\mu\nu} = \partial_\mu G_{\nu} - \partial_\nu G_{\mu}$ its field strength tensor, $A_\mu$ the photon field and $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ its field strength tensor, $\psi$ the electron field and $q$ the quark field. We have a quark field with two flavours and $\gamma_5$ is the usual Pauli matrix.

The Hamiltonian corresponding to (24) can be obtained as usual by a Legendre transformation. Only the interaction term has to be altered in order to construct the Hamilton operator for the modified theory

$$\hat{H}_1(y) = \int d^3y \left[ \theta (-y^0) \hat{H}_1(y) - \theta (y^0) \hat{H}_1(y) \right]$$
with $\bar{y} = (-y^0, \vec{y})$. \hspace{1cm} (25)
In $\hat{H}_I(g)$ the fields at time $-y^0$ have to be substituted by the fields at time $y^0$. Two points should be stressed: First, due to the jump in the interaction, the effective theory has no time translation invariance, so that no longer energy conservation holds at every vertex. Second, the effective interaction contains derivatives.

4.2. Inclusive Quark Production in $e^+ e^-$. 

In order to calculate $\mathcal{M}$ we expand it in powers of the electromagnetic coupling constant $\alpha$. The electromagnetic interaction of the incoming fermions can be separated

$$C^e(p_1, p_2, p_3) = \mathcal{Z}_q^{-1} \epsilon^e Q_0^2 \mu^2 \left| \frac{1}{s - \lambda^2 + i\epsilon} \right|^2$$

$$\int d^4 x e^{iy \cdot x} \theta(-x^0) \sum_{s_q} \mathcal{G}(p_3) \left( i \frac{p_3^0}{p_3^0} - M \right) \langle 0 \mid T_{qA}(x + z) \rangle$$

$$\frac{1}{s - \lambda^2 + i\epsilon} e^{-i\mathcal{S}(p_1 + p_2) x^2 \vec{q}(x_2) \gamma_\mu q(x_2)}$$

$$\int d^4 x \left[ \theta(-x^0) e^{-i(p_1 + p_2) x^2 \vec{q}(x_2) \gamma_\mu q(x_2)} - \theta(x^0) e^{-i(p_1 + p_2) x^2 \vec{q}(x_2) \gamma_\mu q(x_2)} \right]$$

$$\delta^{(1)}(p^2 - M^2) \theta(p^0) \left|_{p_1 + p_2 + p_3} \right. \left|_{p_1 + p_2 + p_3} \right.$$ (26)

As a simple check of our theoretical manipulations let us finally calculate the lowest order in the quark-gluon-coupling $g$, i.e. for $g = 0$. Decomposing the quark 6-point-functions with Wick’s

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1.png}
\caption{Lowest order contributions.}
\end{figure}

The distinction between both contributions is given by the fact, that the upper diagram has got an imaginary part, whereas the lower one is completely real so that we get only a contribution from the upper diagram

$$\mathcal{F}_{inc}(p_3) = \frac{1}{2(2\pi)^3 w} \pi^e Q_0^2 \mu^2 \left| \frac{1}{s - \lambda^2 + i\epsilon} \right|^2$$

$$2 \sum_{s_q} \mathcal{G}(p_3) \gamma_\mu (p - M) \gamma_\mu u(p_3)$$

$$\delta^{(1)}(p^2 - M^2) \theta(p^0) \left|_{p_1 + p_2 + p_3} \right.$$ (28)

which is, of course, the standard result, which one obtains in considering to lowest order the reaction

$$e^+ e^- \rightarrow q + \bar{q}$$ (29)

for two quark flavours of charge $Q_q$. 

\[\]
4.3. Path Integral Representation

In the last subsection $\mathcal{M}$ and therefore the one-quark-inclusive cross-section could be expressed in terms of quark $6$-point-functions after separating the electromagnetic interaction by a perturbative calculation. As the coupling $g$ is not assumed to be small we will now derive a representation of these quark $6$-point-functions suitable for non-perturbative calculations. For this we consider the Hamiltonian path integral in our effective theory obtained from the abelian gluon model.

Any Green’s function of the theory can be written as

$$\langle 0 | T q(x_1) \cdots \overline{q}(x_2) \cdots | 0 \rangle$$

$$= \hat{Z}^{-1} \int \mathcal{D}(G, \Pi_G, q, \overline{q}) \ q(x_1) \cdots \overline{q}(x_2) \cdots \times \exp \left\{ i \int d^4 y \ (\Pi(y) \hat{\Phi}(y) - \overline{\mathcal{H}}(y)) \right\}$$

with

$$\hat{Z} = \int \mathcal{D}(G, \Pi_G, q, \overline{q}) \times \exp \left\{ i \int d^4 y \ (\Pi(y) \hat{\Phi}(y) - \overline{\mathcal{H}}(y)) \right\}. \ (31)$$

Here the classical fields $G$ and $\Pi_G$ and the Grassmann fields $q$ and $\overline{q}$ have to be inserted into the part of $\overline{\mathcal{H}}(y)$ (25) which describes the abelian gluon model. Furthermore for $y^0 > 0$ the classical and Grassmann fields have to be time-shifted.

As the Hamiltonian path integral is quadratic in $q, \overline{q}$, the fermionic fields can be integrated out. With the Green’s function $\mathcal{S}_P$ of the quark in the modified gluon background

$$(i\delta_+ M_0 - g \delta(z_1)) \mathcal{S}_P(z_1, z_2; G) = -\delta(z_1 - z_2), \quad \overline{\mathcal{H}}, \ (32)$$

the quark propagator is given as

$$(0 \left| Tq(z_1) \overline{q}(z_2) \right| 0) = \mathcal{S}_P(z_1, z_2; G), \quad \overline{\mathcal{H}}, \ (33)$$

where the brackets $\langle \rangle$ on the right hand side denote the average over all gluon fields with the measure dictated by the path-integral

$$\langle F(G, \Pi_G) \rangle = \hat{Z}^{-1} \int \mathcal{D}(G, \Pi_G) F(G, \Pi_G) \times \exp \left\{ i \int d^4 y \ (\Pi(y) \hat{\Phi}(y) - \overline{\mathcal{H}}(y)) \right\} \quad \overline{\mathcal{H}}, \ (34)$$

Inserting the Green’s function into the matrix element we get the inclusive cross section expressed explicitly in terms of a Hamiltonian path integral. This expression should be a convenient starting point for applying non-perturbative methods to an evaluation of inclusive cross sections. It should be possible, for instance, to generalise the methods of [6] to the case of this effective theory here.

5. CONCLUSIONS

We have written the inclusive cross section as imaginary part of an amplitude $\mathcal{C}$ for which we have given a path integral representation. We have applied our formalism to the reaction $e^+ e^- \rightarrow q + X$ and checked that in lowest non-trivial order we get the correct result. Our hope is that our path integral representation will lead to a genuinely non-perturbative evaluation of inclusive cross sections at high energies along the lines of [6]. The generalisation to QCD should be straightforward. Our methods should allow a description of inclusive production of hadrons $h$ in $e^+ e^-$ annihilation at high energies

$$e^+ + e^- \rightarrow h + X$$

in terms of a genuine OPE. A similar approach should be possible for fracture functions [8] for hadron-hadron scattering

$$h_1 + h_2 \rightarrow h_3 + X. \quad \overline{\mathcal{H}}, \ (35)$$
