Abstract. Photoproduction of $D_s^{\pm}$ mesons has been measured in the ZEUS detector at HERA and compared with predictions of NLO pQCD calculations. The ratio of $D_s^{\pm}$ to $D^*^{\pm}$ cross sections has been compared to results from $e^+e^-$ experiments. Orbitally excited P-wave charm mesons have been observed in the $D^{\pm}\pi^\mp$ final state. The fraction of $D^{\pm}$'s originating from these mesons has been calculated and compared with that from $e^+e^-$ interactions. No evidence for radially excited mesons decaying to $D_s^{\pm}\pi^+\pi^-$ was found. The inelastic production of $J/\psi$ mesons has been measured and compared to LO and NLO pQCD predictions.

INTRODUCTION

Charm photoproduction measurements have been performed at the HERA $ep$ collider in the ZEUS detector from data taken during 1995-2000. Electrons or positrons with energy $E_e = 27.5 GeV$ collided with protons of energy $E_p = 820 GeV$ (1995-1997) or $E_p = 920 GeV$ (1998-2000). The ZEUS detector description can be found elsewhere [1].

The decay chain $D_s^{\pm} \rightarrow \phi \pi^\pm \rightarrow K^+K^-\pi^\pm$ (38pb$^{-1}$ integrated luminosity) was studied [2] as a continuation of a previous analysis of charm photoproduction [3]. The study of $D_s^{\pm}$ photoproduction provides another test of next-to-leading order (NLO) perturbative quantum chromodynamics (pQCD) calculations.

Orbitally excited P-wave $D$ mesons can decay to a $D^*$ by pion emission. Two of these states ($D_1(2420)$ and $D_2^*(2460)$) have been found to decay into narrow states [4] with properties predicted by Heavy Quark Effective Theory (HQET) [5] and a third broad state has been seen by the CLEO collaboration [6]. A radial excitation of the $D^{*\pm}$ with a mass of about 2.6 $GeV$ decaying

into $D^{*\pm}\pi^+\pi^-$ has been reported by DELPHI [7] but not seen by OPAL and CLEO [8,9].

Inelastic $J/\psi$ photoproduction proceeds via direct (resolved) processes, where the virtual photon (parton from the photon) interacts with a parton from the incoming proton. In the dominant process, boson gluon fusion (BGF), the latter parton is a gluon. Photon diffraction to $J/\psi$ also contributes. The inelasticity variable, $z = \frac{P \cdot p_{\psi}}{P \cdot q}$, can be used to distinguish these processes. Here $P$, $p_{\psi}$ and $q$ are the four-momenta of the incoming proton, $J/\psi$ and exchanged photon, respectively. From previous ZEUS data [10] the diffractive process dominates at $z > 0.9$, the direct photon process dominates at $0.4 < z < 0.9$. The resolved photon contribution is expected to dominate at $z \lesssim 0.2 [11]$.

Color singlet and color octet models have been used to calculate the above non-diffractive production processes in pQCD. For the former, the charm-anticharm pair ($c\bar{c}$) from the hard process is identified with the physical $J/\psi$ state. In this model in leading order (LO) only the BGF diagram contributes to the direct channel. In the color octet model the $c\bar{c}$ pair from the hard process emits one or more soft gluons to evolve into the physical $J/\psi$ state. The free parameters of the model can be extracted from $J/\psi$ cross-section measurements and used in other inelastic $J/\psi$ production experiments.

### $D^\pm$ PHOTOPRODUCTION

$D^\pm_s$ production was studied for: $Q^2 < 1.0 \, GeV^2, 130 < W_{\gamma p} < 280 \, GeV, 3 < p_{D^\pm_s}^T < 12 \, GeV$, $|\eta^{D^\pm_s}| < 1.5$, where $Q^2$ is the photon virtuality, $W_{\gamma p}$ is the virtual photon proton center of mass energy, $p_{D^\pm_s}^T$ is the transverse momentum of the $D^\pm_s$ and $\eta^{D^\pm_s}$ is the pseudorapidity of the $D^\pm_s$. The effective mass of two opposite charge track combinations, assumed to be kaons, was calculated and plotted in Fig. 1a. A clear enhancement at the $\phi$ mass is seen. The effective mass of the combinations in this enhancement region and another track assumed to be a pion was then obtained. The peak in the $D^\pm_s$ mass region contained $339 \pm 48$ $D^\pm_s$ mesons (Fig. 1b), corresponding to a cross section of $\sigma_{e^+e^- \rightarrow D^+_s X} = 3.79 \pm 0.59(\text{stat})^{+0.26}_{-0.46}(\text{syst}) \pm 0.94(\text{br}) \text{ nb}$.

Distributions in $p_{D^\pm_s}^T$ and $\eta^{D^\pm_s}$ were compared with those for $D^{*\pm}$ production [3] and with a fixed order NLO calculation [12] in which charm was produced by the BGF process. The signal is above the prediction (Fig. 2), particularly for $\eta$ along the proton beam direction, as was the case for $D^{*\pm}$ production.

The ratio of the cross section for $D^\pm_s$ to $D^{*\pm}$ production at HERA has been compared to that from $e^+e^-$ experiments, where the latter result is taken from a recent compilation [13] of fragmentation fractions to charm mesons ($f(c \rightarrow D)$). The results from the two types of interactions are:

\[
\frac{\sigma_{e^+e^- \rightarrow D^+_s X}}{\sigma_{e^+e^- \rightarrow D^{*+} X}} = 0.41 \pm 0.07^{+0.03}_{-0.05} \quad \text{and} \quad \frac{f(c \rightarrow D^+_s)}{f(c \rightarrow D^{*+})} = 0.43 \pm 0.04.
\]
FIGURE 1. (a) $M(K^+K^-)$ distribution for events inside the $D_s^\pm$ mass range, $(1.94 < M(K^+K^-\pi^\pm) < 2.00 \text{GeV})$. The solid curve is a fit to a Breit-Wigner convoluted with a Gaussian-shaped resonance and a background parameterization, $a[M(K^+K^-) - 2m_K]^b$. (b) $M(K^+K^-\pi^\pm)$ distribution for events in the $\phi$ mass range, $(1.0115 < M(K^+K^-) < 1.0275 \text{GeV})$. The solid curve is a fit to a Gaussian plus an exponential background.

FIGURE 2. Differential cross sections for the photoproduction reaction $ep \rightarrow DX$: (a) $d\sigma/dp_T^D$ and (b) $d\sigma/d\eta$, where $D$ stands for $D^*$ or $D_s$. Inner (outer) error bars show statistical (statistical and systematic added in quadrature) errors. The $D_s$ (dots) and $D^*$ (triangles) data are compared with NLO predictions for $D_s$ (full curves) and $D^*$ (dashed curves) with two parameter settings: $m_c = 1.5 \text{GeV}$, $\mu_R = m_\perp$ (thick curves) and $m_c = 1.2 \text{GeV}$, $\mu_R = 0.5m_\perp$ (thin curves).

The strangeness suppression factor, $\gamma_s$, (the ratio of the probability to produce a strange quark to that to produce a non-strange quark), has also been compared to that from $e^+e^-$ experiments. From HERA the value of the above cross section ratio and the PYTHIA Monte Carlo was used and for $e^+e^-$ the quantity $2f(c \rightarrow D_s^+)/[f(c \rightarrow D^0) + f(c \rightarrow D^+)]$ served as an estimator for $\gamma_s$. 
The values of $\gamma_s$ for HERA and $e^+e^-$, respectively, were $0.27 \pm 0.04^{+0.02}_{-0.03}$ and $0.26 \pm 0.03$, implying consistency with universal charm fragmentation.

**EXCITED CHARM MESONS**

As a basis for the study of higher excitations of charm mesons, an enlarged sample of data (integrated luminosity of $110$pb$^{-1}$), containing a clean signal of $D^{*\pm}$ mesons from both photoproduction and deep inelastic scattering, was used [14]. Events in the mass range $1.83 < M(K\pi) < 1.90$GeV, $0.144 < M(K\pi\pi_s) - M(K\pi) < 0.147$GeV were chosen ($\pi_s$ is the low momentum pion in the $D^*$ decay). The background (estimated from events in which the K and $\pi$ in the $D^0$ mass range have the same charge) has been subtracted, yielding $2726 \pm 232$ $D^{*\pm}$.

For orbital excitations an extra track, $\pi_4$, was added to the $D^{*\pm}$ candidate and the effective mass combination, $M(K\pi\pi_s\pi_4) - M(K\pi\pi_s) + M(D^*)(2.010$GeV), was evaluated. An enhancement in the mass distribution with total charge zero is seen in Fig. 3a. This spectrum was fitted to $D^0_1$ and $D^0_2$ Breit-Wigner shapes with masses and widths fixed [4], and convoluted with a Gaussian function with a width as in the Monte Carlo simulation. The background was described by $x^\alpha e^{-\beta x + \gamma x^2}$, where $x = M(K\pi\pi_s\pi_4) - M(K\pi\pi_s) - m_\pi$, with $\alpha$, $\beta$, and $\gamma$ constant. Helicity angle distributions for $D^0_1$ and $D^0_2$ proportional to $1 + 3 \cos^2 \theta$ and $1 - \cos^2 \theta$, respectively, were folded in for the fit. Here, $\theta$ is the angle between $\pi_4$ and $\pi_s$ in the $D^{*\pm}$ rest frame. A closer look, (Fig. 3b), indicates an excess of events in the expected mass range, (2.59 – 2.67 GeV) (Fig. 4). An upper limit was obtained by fitting the background outside this range, interpolating within the range and subtracting this from the data in the mass range. The 95% confidence level upper limit for the $D^{*\pm}\pi^+\pi^-$ decay relative to $D^{*\pm}$ was found to be 2.3%. Extrapolating to the full kinematic range and using [13], $f(c \rightarrow$
\( M(K\pi\pi_s\pi^4) - M(K\pi\pi_s) + M(D^*) \) (GeV)

Inset: Dashed histogram is the Monte Carlo signal normalized to the upper limit and added to the fit interpolation (dotted curve) in the $D^{*\pm}$ window.

INELASTIC $J/\psi$ PRODUCTION

The $\mu^+\mu^-$ decay channel of $J/\psi$ for $0.4 < z < 0.9$, $50 < W_{\gamma p} < 180$ GeV and $Q^2 < 1$ GeV$^2$, using the 1996-1997 data, has been studied [19]. Distributions in $z$, rapidity and transverse momentum squared of the $J/\psi$ and a comparison with theoretical expectations are shown in Fig. 5. The $z$ dependence of the data is not described in magnitude by the LO color singlet and octet model with octet matrix elements calculated from the CDF data [20,23]. On the other hand, the NLO color singlet model [21] roughly fits the spectrum for $p_{T\psi} > 1$ GeV. For $p_{T\psi} > 2$ GeV the LO model with octet matrix elements from CLEO data agrees with the data for high $z$ only [22,24]. Currently there is no calculation in NLO for the rapidity distribution. The NLO calculation agrees with the $p_{T\psi}^2$ data.

ACKNOWLEDGMENT

It is a pleasure to thank the organizers for a stimulating and enjoyable meeting.
FIGURE 5. (a) $z$ distribution for various $p_{T\psi}$ cuts: no cut (squares), $p_{T\psi} > 1\,\text{GeV}$ (circles) and $p_{T\psi} > 2\,\text{GeV}$ (triangles). Inner (outer) error bars are statistical (quadratic sum of statistical and systematic) errors. Lower pair of solid curves are a prediction of color singlet and octet model [20] for $p_{T\psi} > 1\,\text{GeV}$. Separation of the curves indicates the uncertainty in the color octet matrix elements. Upper pair of solid curves includes a scale factor of $\sim 3$. Dotted curve is the color singlet NLO prediction for the direct photon process and $p_{T\psi} > 1\,\text{GeV}$ [21]. Dashed curve is prediction of the color singlet and octet models for $p_{T\psi} > 2\,\text{GeV}$ [22]. (b) Rapidity distribution for $p_{T\psi} > 1\,\text{GeV}$. Solid curves as in (a). Dotted curve is the LO contribution of the direct photon color singlet component. (c) $p_{T\psi}^2$ distribution: Solid curve is the prediction of the NLO calculation [21].
