Abstract

We study fine differentiability properties of horizons. We show that the set of end points of generators of a \( n \)-dimensional horizon \( \mathcal{H} \) (which is included in a \( (n + 1) \)-dimensional space-time \( M \)) has vanishing \( n \)-dimensional Hausdorff measure. This is proved by showing that the set of end points of generators at which the horizon is differentiable has the same property. For \( 1 \leq k \leq n + 1 \) we show (using deep results of Alberti) that the set of points where the convex hull of the set of generators leaving the horizon has dimension \( k \) is “almost a \( C^2 \) manifold of dimension \( n + 1 - k \): it can be covered, up to a set of vanishing \( (n + 1 - k) \)-dimensional Hausdorff measure, by a countable number of \( C^2 \) manifolds. We use our Lorentzian geometry results to derive information about the fine differentiability properties of the distance function and the structure of cut loci in Riemannian geometry.

1 Introduction.

Horizons are amongst the most important objects that one encounters in causality theory: Cauchy horizons constitute boundaries beyond which predictability breaks down; event horizons are boundaries
The dimension of $H$ one control over the size of the set of endpoints with multiplicity which a horizon is non-differentiable has vanishing horizons are non-differentiable precisely at this set. It is also well known that the set of points at determines the differentiability properties of horizons: as has been shown by Beem and Królik [2], horizons are non-differentiable precisely at this set. It is also well known that the set of points at which a horizon is non-differentiable has vanishing $n$-dimensional Hausdorff measure, and this gives one control over the size of the set of endpoints with multiplicity $N(p) > 1$. Thus, in order to control the dimension of $\mathcal{H}_{\text{end}}$ it remains to estimate that of the set of endpoints with multiplicity $N(p) = 1$. Let us denote by $\mathcal{H}_{\text{diff}}$ the set of points of $\mathcal{H}$ at which $\mathcal{H}$ is differentiable; what has been said shows that the set of endpoints with multiplicity $N(p) = 1$ coincides with the set $\mathcal{H}_{\text{end}} \cap \mathcal{H}_{\text{diff}}$. Królik and Beem [2] have displayed an example of a horizon with an endpoint with multiplicity one (at which $\mathcal{H}$ is, of course, differentiable), thus there exist horizons for which the set $\mathcal{H}_{\text{end}} \cap \mathcal{H}_{\text{diff}}$ is not empty. Our first main result is the following:

**Theorem 1** Let $\mathcal{H}$ be a future horizon in an $(n+1)$-dimensional spacetime $(M, g)$. Then the set $\mathcal{H}_{\text{end}} \cap \mathcal{H}_{\text{diff}}$ has vanishing $n$-dimensional Hausdorff measure. Moreover, for any $C^2$ spacelike hypersurface the set $\mathcal{H}_{\text{end}} \cap \mathcal{H}_{\text{diff}} \cap$ has vanishing $(n - 1)$-dimensional Hausdorff measure.

The set of points where the multiplicity $N(p)$ is large has a more precise structure. To describe this, equip $M$ with an auxiliary complete Riemannian metric $\sigma$, and for each $p \in \mathcal{H}$ let $N_p^{+}$ be the set of future pointing $\sigma$-unit vectors that are tangent to a generator of $\mathcal{H}$ at $p$. We call such vectors semi-tangents to $\mathcal{H}$. Then the number of vectors in $N_p^{+}$ is just the multiplicity $N(p)$ of $p$. Define

\[ C_p := \text{convex cone generated by } N_p^{+} . \]

We can measure the size of the set of generators through $p$ by $\dim(C_p)$ (which is the dimension of the linear span of $C_p$ in $T_p M$). This is a different measure than is $N(p)$; in particular this gives finer information when $N(p) = \infty$. We also set

\[ \mathcal{H}[k] := \{ p : \dim(C_p) \geq k \} . \]  

(1.1)

For $k = 1$, $\mathcal{H}[k] = \mathcal{H}$ as every point is on at least one generator. For $k = 2$, $\mathcal{H}[k]$ is the set of points of $\mathcal{H}$ that are on more than one generator. As $\dim(C_p)$ is the dimension of the span of $N_p^{+}$ and $N_p^{+}$ contains $N(p)$ vectors, $\dim(C_p) \leq N(p)$. This implies

\[ \mathcal{H}[k] \subseteq \{ p \in \mathcal{H} : N(p) \geq k \} . \]

Also, for $1 \leq k \leq 3$, any $k$ distinct elements of $N_p^{+}$ are linearly independent.\(^1\) Therefore if $1 \leq k \leq 3$ and $N(p) \geq k$ then choosing $k$ distinct, and thus linearly independent, elements of $N_p^{+}$, shows that $\dim(C_p) \geq k$. Whence

\[ \mathcal{H}[k] = \{ p \in \mathcal{H} : N(p) \geq k \} \quad \text{for } 1 \leq k \leq 3 . \]

\(^1\)The linear span of two future pointing $\sigma$-unit null vectors is a two dimensional timelike subspace and there are only two future pointing null rays in this subspace. So a third future pointing $\sigma$-unit vector can not be in the span of the first two.
Our next main result, based on the deep results\(^2\) in [1], is that the sets \(\mathcal{H}[k]\) are “almost \(C^2\) submanifolds of dimension \(n + 1 - k\), up to singular sets of lower dimension”.\(^3\) To make this statement precise, let \(\mathcal{S}^m\) be the \(m\)-dimensional Hausdorff measure on \(M\) (defined with respect to some Riemannian metric \(\sigma\) on \(M\)). Recall, [1, Def. 1.1 p.19] a Borel set \(\Sigma \subset M\) is a \((\mathcal{S}^m, m)\) rectifiable set of class \(C^2\) if \(\Sigma\) can be covered, up to a set of vanishing \(\mathcal{S}^m\) measure, by a countable collection of \(m\)-dimensional \(C^2\) submanifolds of \(M\). This definition is independent of the choice of the Riemannian metric \(\sigma\). Following [1] we will shorten “\((\mathcal{S}^m, m)\) rectifiable set of class \(C^2\)” to “\(C^2\) rectifiable of dimension \(m\)”.

**Theorem 2** For \(1 \leq k \leq n + 1\) the set \(\mathcal{H}[k]\) is a \(C^2\) rectifiable set of dimension \(n + 1 - k\). Therefore \(\mathcal{H}[k]\) has Hausdorff dimension \(\leq n + 1 - k\).

Using \(k = 1\), and that \(\mathcal{H}[1] = \mathcal{H}\), this implies that horizons are \(C^2\) rectifiable of dimension \(n\). As they are also locally Lipschitz graphs they have the further property that \(\mathcal{S}^n(\mathcal{H} \cap K) < \infty\) for all compact sets \(K \subset M\). When \(k = n + 1\) this implies that \(\mathcal{H}[n+1]\) is a countable set (cf. Remark 6 below).

## 2 Proof of Theorem 1

We shall prove the second part of the theorem; the first part follows immediately from the second and the co-area formula. Let, then, be as in Theorem 1; since the result is purely local, without loss of generality we may assume that is the level set \(\{t = 1\}\) of a time function \(t\), with range \(\mathbb{R}\), the level sets of which are Cauchy surfaces. We use the constructions and notations of [4], with \(\Sigma_1 = \Sigma_2 = \{t = 2\}\). Let

\[\hat{S}_1 = \cap \mathcal{H}_{\text{end}} \cap \mathcal{H}_{\text{diff}},\]

and let \(A, \phi\) be defined as at the beginning of the proof of Theorem 6.1 in [4]. Hence, \(A\) is the subset of \(S_2 = \Sigma_2 \cap \mathcal{H}\) consisting of those points in \(S_2\) that are met by the generators of \(\mathcal{H}\) that meet \(S_1 = \Sigma_1 \cap \mathcal{H}\), and \(\phi : A \to S_1\) is the map that moves the points of \(A\) back along these generators to \(S_1\). We can choose the auxiliary Riemannian metric \(\sigma\) on \(M\) so that \(dt\) has unit length with respect to this metric. Then \(A\) is an \(A_\delta\) set as defined by Equation (6.6) of [4], with \(\delta = 1\). We set

\[\hat{A} = \phi^{-1}(\hat{S}_1) \subset A \subset S_2;\]

thus, the points in \(\hat{A}\) are precisely those points on \(\Sigma_2 \cap \mathcal{H}\) the generators through which exit \(\mathcal{H}\), when followed to the past, at the differentiable end points on \(\mathcal{H}\).

For \(i = 1, 2\), let \(\mathcal{S}_{h_i}^{n-1}\) denote the \((n - 1)\)-dimensional Hausdorff measure on \(\Sigma_i\) with respect to the distance function determined by the induced metric \(h_i\) on \(\Sigma_i\). By a straightforward extension of the proof of [4, Proposition 6.14] one has for any \(\mathcal{S}_{h_2}^{n-1}\)-measurable subset \(\Omega\) of \(A\),

\[
\int_{S_1} N(p, S_2) 1_{\phi(\Omega)} d\mathcal{S}_{h_1}^{n-1}(p) = \int_{\Omega} J(\phi)(q) d\mathcal{S}_{h_2}^{n-1}(q),
\]

where \(1_U\) denotes the characteristic function of the set \(U\), and \(J(\phi)\) is, in a suitably defined sense (cf. [4], Prop. 6.14), the Jacobian of the locally Lipschitz function \(\phi\).

In Proposition 3 below we show that there exists a \(\mathcal{S}_{h_2}^{n-1}\)-negligible set \(\hat{A}' \subset \hat{A}\) such that \(J(\phi)(q) = 0\) for all \(q \in \hat{A} \setminus \hat{A}'\). It then follows that,

\[
\hat{A} \subset \Omega \equiv \{ q \in A : J(\phi) = 0 \} \cup \hat{A}'.
\]

---

\(^2\)The reader is warned that the dimension index \(k\), in \(\mathcal{H}[k]\), is shifted by one, as compared to that used in Theorem 3 of [1]; compare the remarks following Definitions 1.5 and 1.7 in [1].

\(^3\)We note a related result of [12], where it is shown that the set \(N(p) = 2\) is, up to a lower dimensional set, a smooth submanifold of co-dimension two for the horizons considered there.
Ω, as defined above, is the union of a $\mathcal{H}^n_{h^2}-1$-measurable set and a $\mathcal{H}^n_{h^2}-1$-negligible set, and hence is itself $\mathcal{H}^n_{h^2}-1$-measurable. Equation (2.1) then shows that $\phi(\Omega)$ is $\mathcal{H}^n_{h^2}-1$-negligible. Now, since $\hat{S}_1 \subset \phi(\Omega)$, the result follows.

It thus remains to establish the following.

**Proposition 3** $J(\phi)(q) = 0$ for $\mathcal{H}^n_{h^2}-1$-almost all $q \in \hat{A}$.

**Proof:** We use the definitions, constructions and notations of the proof of [4, Prop. 6.16]. Thus, let $U \subset \Sigma_2$ be a coordinate neighborhood of the form $V \times (a, b)$, with $V \subset \mathbb{R}^{n-1}$ and $a, b, \in \mathbb{R}$, in which $U \cap N$ is the graph of a $C^1,1$ function $g : V \to \mathbb{R}$, and in which $\mathcal{H} \cap U$ is the graph of a semiconvex function $f : V \to \mathbb{R}$. Here $N = N_g$ is a locally $C^1,1$ hypersurface in $\Sigma_2$ into which $A$ has been embedded. Let $pr A$ denote the projection onto $V$ of $A \cap U$, thus $A \cap U$ is the graph of $g$ over $pr A$.

Now, let $x_0 \in \hat{B} \cap pr \hat{A}$, where $\hat{B}$ is the set of full measure in $pr A$ constructed in the proof of [4, Prop. 6.16], and $pr \hat{A}$ is the projection onto $V$ of $A \cap U$. Since $g$ is Lipschitz, the graph of $g$ over $\hat{B} \cap pr \hat{A}$ has full measure in $\hat{A}$. Let $q_0 = (x_0, f(x_0)) \in \hat{A}$ be the corresponding point on $\mathcal{H} \cap \Sigma_2$, thus the generator $\Gamma$ of $\mathcal{H}$ passing through $q_0$ exits the horizon at a point $p \in \mathcal{H} \cap \Sigma_2$. Let $\hat{\Gamma}$ be any null geodesic which extends $\Gamma$ to the past, and let $p_n$ be any sequence of points on $\hat{\Gamma}$ which are to the causal past of $p$ and which approach $p$ as $n$ tends to infinity. Since $\hat{\Gamma}$ is a null geodesic which exits $\mathcal{H}$ at $p$, the $p_n$'s lie on the timelike past $I^-(\mathcal{H})$ of $\mathcal{H}$. Thus the integral curve $\gamma_n$ of $\frac{\partial \phi}{\partial t}$ starting at $p_n$ meets $\mathcal{H}$ at some point $r_n \in \gamma_n \cap \mathcal{H}$. One can then construct a causal curve from $p_n$ to $\mathcal{H} \cap \Sigma_2$ by following $\gamma_n$ from $p_n$ to $r_n$, and any generator of $\mathcal{H}$ passing through $r_n$; as $(M, g)$ is globally hyperbolic this generator will necessarily intersect $\Sigma_2$. It follows that there exists a timelike curve $\hat{\gamma}_n \subset I^-(\mathcal{H})$ from $p_n$ to $\mathcal{H} \cap \Sigma_2$. By the compactness of the space of causal curves, passing to a subsequence if necessary, the $\hat{\gamma}_n$'s converge (in a well known sense) to a causal curve $\gamma$ from $p$ to a point $q \in \mathcal{H} \cap \Sigma_2$. The achronality of $\mathcal{H}$ shows that $\gamma$ is a generator of $\mathcal{H}$ passing through $p$, hence $\gamma = \Gamma$ and $q = q_0$.

Now suppose that $J(\phi)(q_0) \neq 0$. By the construction of the set $\hat{B}$, there exists $g_j \in C^2(V)$, approximating $g$, such that $S_j$, the graph of $g_j$, is a $C^2$ hypersurface in $\Sigma_2$ which, in a well defined sense, makes second order contact with $\mathcal{H} \cap \Sigma_2$ at $q_0$. (More precisely, $g_j$ and $f$, as well as their first derivatives, agree at $q_0$, and the second derivative of $g_j$ agrees with the so-called second Alexandrov derivative of $f$ at $q_0$.) Since $S_j$ is tangent to $\mathcal{H} \cap \Sigma_2$ at $q_0$, the null geodesics $\hat{\Gamma}$ is normal to $S_j$ at $q_0$. Let $\phi_j : S_j \to$ be the $C^1$ map which moves the points of $S_j$ along the family of null geodesics normal to $S_j$ which includes $\hat{\Gamma}$. Then we have $J(\phi_j(q_0)) = J(\phi)(q_0) \neq 0$, cf. [4, Equation (6.40)]. Define $g_{j,\varepsilon} \in C^2(V)$ by

$$g_{j,\varepsilon}(x) = g_j(x) + \varepsilon|x - x_0|^2, \quad (2.3)$$

and let $S_{j,\varepsilon}$ be the graph of $g_{j,\varepsilon}$ for $\varepsilon > 0$, $S_{j,\varepsilon} \subset I^+(\mathcal{H})$ and $S_{j,\varepsilon} \setminus \{q_0\} \subset I^+(\mathcal{H})$. Note that as $S_{j,\varepsilon}$ is tangent to $S_j$ at $q_0$, $\hat{\Gamma}$ is normal to $S_{j,\varepsilon}$ at $q_0$.

The fact that the Jacobian of $\phi_j$ is nonzero at $q_0$ implies that $p$ is not a focal point to $S_j$ along $\hat{\Gamma}$. Moreover, there can be no focal points to $S_j$ along the segment of $\hat{\Gamma}$ to the future of $p$, cf. [4, Lemma 4.15]. It follows that by taking $\varepsilon$ small enough and $\hat{\Gamma}$ short enough, there will be no focal points to $S_{j,\varepsilon}$ along $\hat{\Gamma}$. This implies by normal exponentiation that there exists an embedded $C^2$ null hypersurface $N_{j,\varepsilon}$ which contains $\hat{\Gamma}$ and, by shrinking it if necessary, $S_{j,\varepsilon}$, as well, cf. [4, Prop. A3]. Moreover, there exists a neighborhood $O$ of $\hat{\Gamma}$ in which $N_{j,\varepsilon}$ is achronal: Indeed, since spacetime is time orientable, $N_{j,\varepsilon}$ is a two-sided connected embedded hypersurface in $M$. As such $N_{j,\varepsilon}$ admits a connected neighborhood $O$ which is separated by $N_{j,\varepsilon}$ ($N_{j,\varepsilon} \subset O$, and $O \setminus N_{j,\varepsilon}$ consists of two components). Then a future directed timelike curve joining points of $N_{j,\varepsilon}$ would be a timelike curve from the future side of $N_{j,\varepsilon}$ to the past side of $N_{j,\varepsilon}$, which is impossible if the curve remains in $O$. We conclude that $N_{j,\varepsilon}$ is achronal in $O$.

Consider now the timelike curves $\hat{\gamma}_n \subset J^-(\mathcal{H})$ constructed earlier in the proof; since the $\hat{\gamma}_n$'s converge to $\Gamma$ there exists $n_0$ such that all the $\hat{\gamma}_n$'s are entirely contained in $O$ for $n \geq n_0$. Moreover, by taking $n_0$ larger if necessary, it is clear that each such $\hat{\gamma}_n$ will meet the hypersurface $P$ in $M$
obtained by pushing $S_{j,\varepsilon}$ to the past along the integral curves of $-\frac{\partial}{\partial t}$. One can then construct a timelike curve from $p_n$ to $S_{j,\varepsilon}$ contained in $\mathcal{O}$ by following $\dot{\gamma}_n$ from $p_n$ to $P$, and then an integral curve of $\frac{\partial}{\partial t}$ to $S_{j,\varepsilon}$. This contradicts the achronality of $N_{j,\varepsilon}$ in $\mathcal{O}$, and establishes Proposition 3. \hfill $\square$

3 Proof of Theorem 2

We start by showing that $\mathcal{H}$ has no worse regularity than being the boundary of a convex set:

**Proposition 4** For any point $p \in \mathcal{H}$ there is a coordinate system $x^1, \ldots, x^{n+1}$ defined on an open set $U \subseteq M$ so that $\mathcal{H} \cap U$ is given by the graph $x^{n+1} = h(x^1, \ldots, x^n)$ of a convex function $h$.

**Proof:** It is shown in [4, Theorem 2.2] that $\mathcal{H}$ is locally the graph of a semi-convex function. That is, there is a coordinate system $y^1, \ldots, y^{n+1}$ so that $U \cap \mathcal{H}$ is given by a graph $y^{n+1} = u(y^1, \ldots, y^n) + h(x^1, \ldots, x^n)$ where $u$ is $C^\infty$ and $h$ is convex. Define new coordinates by $x^i = y^i$ for $i = 1, \ldots, n$ and $x^{n+1} = y^{n+1} - u(x^1, \ldots, x^n)$ in these coordinates $\mathcal{H}$ is given by $x^{n+1} = h(x^1, \ldots, x^n)$. \hfill $\square$

Recall that a convex body in a finite dimensional vector space has a well defined normal cone at each of its boundary points $p$. One definition of this tangent cone is the set of linear functionals on the vector space such that their restrictions to the body attain a maximum at the point $p$. The following is an adaptation of this definition to manifolds which allows us to define the tangent cones $\text{Nor}_p(J^+(\mathcal{H}))$ to $J^+(\mathcal{H})$ at points $p \in \mathcal{H} = \partial J^+(\mathcal{H})$ in an invariant manner.

$$\text{Nor}_p(J^+(\mathcal{H})) := \{df(p) : f \in C^\infty(M, \mathbb{R}) \text{ and } f|_{J^+(\mathcal{H})} \text{ has a local max. at } p\}.$$ 

The following is a special case of a main result in the paper of Alberti [1, Thm 3 p. 18] adapted to our notation.

**Proposition 5 (Alberti)** Let $B$ be a convex body in an $n+1$-dimensional vector space. For each $k = 1, 2, \ldots, n+1$ let $\partial B[k]$ be the set of points $p \in \partial B$ so that $\dim \text{Nor}_p(B) \geq k$. Then $\partial B[k]$ is a $C^2$ rectifiable set of dimension $n+1-k$. Therefore the Hausdorff dimension of $\partial B[k]$ is less than or equal to $n+1-k$. \hfill $\square$

**Remark 6** The top and bottom dimensional cases of this are worth remarking on. When $k = n+1$ this implies that $\partial B[n+1]$ is a $C^2$ rectifiable set of dimension 0. But then, [1, Theorem 3 and Definition 1.1], $\partial B[n+1]$ is a countable union of sets of finite $\mathcal{H}^0$ measure. However the zero dimensional measure $\mathcal{H}^0$ is just the counting measure, [9, p. 171], so that $\mathcal{H}^0(A)$ is just the number of points in $A$. Therefore $\partial B[n+1]$ is countable as it is a countable union of finite sets. Consider, next, $k = 1$; as $\dim \text{Nor}_p(J^+(\mathcal{H})) \geq 1$ for all $p \in \partial B$ we have $\partial B = \partial B[1]$ and therefore $\partial B$ is a $C^2$ rectifiable set of dimension $n$. Because $\partial B$ is also locally the graph of a Lipschitz function it has the further property that $\mathcal{H}^0(K \cap \partial B) < \infty$ for all compact sets $K$. The corresponding fact is not true for $\partial B[k]$ when $2 \leq k \leq n+1$ (cf. [1, Thm. 2 p. 18]).

Theorem 2 follows immediately from this, Proposition 4, and

**Lemma 7** For each $p \in \mathcal{H}$ the normal cone $\text{Nor}_p(J^+(\mathcal{H}))$ is given by $\text{Nor}_p(J^+(\mathcal{H})) = \langle v, \cdot \rangle : v \in \mathcal{C}_p \rangle$.

**Proof:** We choose a coordinate system $x^1, \ldots, x^{n+1}$ on a open set $U$ containing $p$ as in Proposition 4 so that $\mathcal{H} \cap U$ is given by $x^{n+1} = h(x^1, \ldots, x^n)$ where $h$ is convex. We may assume that the point $p$ has coordinates $(0, \ldots, 0)$. We also assume that $U$ is of the form $V \times (a, b)$ for $V$ an open convex
set in $\mathbb{R}^n$ and that $h$ takes values in the interval $(a,b)$. Then $h$ is locally Lipschitz and thus the Clarke differential $\partial h(0)$ exists and is a compact convex set of linear functionals on $\mathbb{R}^n$ ([7, pp. 27–28]). As $h$ is convex $\partial h(0)$ is just the set of sub-differentials to $h$ at 0 in the sense of convex analysis ([7, Prop. 2.2.7 p. 36]). It follows that for $q \in \mathcal{H} \cap U$ if we write $q = (x, h(x))$ with $x \in V$ that

$$\text{Nor}_q(J^+(\mathcal{H})) = \{\lambda(\alpha - dx^{x+1}) : \lambda \geq 0, \alpha \in \partial h(x)\}.$$  

There is another useful description of $\partial h(0)$. Let $\Omega_h$ be the set of points $x$ in $V$ where the classical derivative $dh(x)$ exists. As $h$ is locally Lipschitz $\Omega_h$ has full measure in $V$. Let $\mathcal{L}_0$ be the set

$$\mathcal{L}_0 := \left\{ \lim_{\ell \to \infty} dh(x_\ell) : x_\ell \in \Omega_h, \ x_\ell \to 0, \text{ and } \lim_{\ell \to \infty} dh(x_\ell) \text{ exists} \right\}.$$  

of limit points of sequences $\{dh(x_\ell)\}$ of sequences $\{x_\ell\} \subset \Omega_h$ with $x_\ell \to 0$. Then, [7, Thm 2.5.1 p. 63],

$$\partial h(0) = \text{convex hull of } \mathcal{L}_0.$$  

Letting, as in the introduction, $\mathcal{H}_{\text{diff}}$ be the set of points where $\mathcal{H}$ is differentiable, if $x \in V$ and $q = (x, h(x)) \in \mathcal{H}$, then $x \in \Omega_h$ if and only if $q \in \mathcal{H}_{\text{diff}}$. By the theorem of Beem and Królak [2] this is the case if and only if $q$ is on exactly one generator of $\mathcal{H}$. If $q = (x, h(x)) \in \mathcal{H}_{\text{diff}}$ then let $v_q \in \mathcal{N}^+_q$ be the unique semi-tangent to $\mathcal{H}$ at $q$. Then at $q$ the tangent plane to $\mathcal{H}$ can be defined either in terms of $dh$ or in terms of $v_q$ to be the set of vectors $X \in T_q(M)$ so that $(dh - dx^{x+1})(q)(X) = 0$ or $\langle v_q, X \rangle = 0$. Thus there is a positive scalar $\lambda$ so that $(dh - dx^{x+1})(q) = \lambda \langle v_q, \cdot \rangle$. Therefore the normal cone at $q$ is one dimensional and

$$\text{Nor}_q(J^+(\mathcal{H})) = \{\lambda \langle v_q, \cdot \rangle : \lambda \geq 0\} = \{\lambda(dh - dx^{x+1}) : \lambda \geq 0\}.$$  

It follows from this that if $\{x_\ell\} \subset \Omega_h$ and $q_\ell = (x_\ell, h(x_\ell))$ then $x_\ell \to 0$ if and only if $q_\ell \to p$ and $dh(x_\ell) \to \alpha$ if and only if $v_\ell \to v$ where $\langle v, \cdot \rangle = \alpha$. Unraveling all this and using (3.1) and (3.2) gives that in order to complete the proof it is enough to show

$$\mathcal{N}^+_p = \left\{ \lim_{\ell \to \infty} v_\ell : q_\ell \in \mathcal{H}_{\text{diff}}, q_\ell \to p, \text{ and } \lim_{\ell \to \infty} v_\ell \text{ exists} \right\}. $$  

Denote the right side of this equation by $T_p$. Then, [4, Lemma 6.4], the set of semi-tangents $\mathcal{N}^+_p$ is a closed subset of $T(M)$ and therefore $T_p \subseteq \mathcal{N}^+_p$. If $v \in \mathcal{N}^+_p$ then there is a generator $c: [0, \infty) \to M$ with $c(0) = p$, $c'(0) = v$ and parameterized so that it is unit speed with respect to the auxiliary Riemannian metric $\sigma$. For each positive integer $\ell$, $c(1/\ell)$ is an interior point of the generator $c$ and thus $c(1/\ell) \in \mathcal{H}_{\text{diff}}$. Then $v_{c(1/\ell)} = c'(1/\ell)$ and $\lim_{\ell \to \infty} v_{c(1/\ell)} = \lim_{\ell \to \infty} c'(1/\ell) = c'(0) = v$. Thus $v \in T_p$, which yields $\mathcal{N}^+_p \subseteq T_p$. This shows (3.3) holds and completes the proof of the lemma and therefore of Theorem 2.

\section{Application to distance functions and cut loci in Riemannian Manifolds.}

Let $(S, h)$ be a connected Riemannian manifold which we do not assume to be complete. Let $C \subset S$ be a closed set. Then define the distance function $\rho_C: S \to [0, \infty)$ by

$$\rho_C(p) := \text{infimum of lengths of smooth curves in } S \text{ connecting } p \text{ to } C.$$  

This will be Lipschitz with Lipschitz constant one: $|\rho_C(p) - \rho_C(q)| \leq d(p, q)$ where $d(p, q)$ is the Riemannian distance between $p$ and $p$.  

6
We will see that regularity properties of $\rho_C$ and the cut locus of $C$ in $S$ are closely related to the regularity properties of horizons, by looking at the graph of $\rho_C$ (cf. Proposition 9). In this setting it is natural to consider the problem even when $(S, h)$ is not complete. For example when $S$ is the interior of a manifold $P$ with boundary then $\rho_C$ agrees with the distance from $C$ defined by the infimum of the length of curves from $p$ to $C$ in $P$ so that the results apply to that case as well. Also in the setting of Lorentzian geometry one can use the graphs of functions $\rho_C$ to construct examples of horizons regardless of completeness of $(S, h)$.

Let $I \subset \mathbb{R}$ be an interval (which may be open, closed, or half open). Then a *C-minimizing segment* on $I$ is a unit speed geodesic $\gamma: I \to S$ so that

$$\rho_C(\gamma(s)) = s \quad \text{for all} \quad s \in I .$$

We emphasize that we do not assume that $I$ contains 0. The Riemannian equivalent of the fact that horizons are null-geodesically-ruled is contained in the following proposition:

**Proposition 8** Every $p \in S \setminus C$ is on at least one $C$-minimizing segment.

**Proof:** Let $U$ be a convex normal neighborhood of $p$, having closure disjoint from $C$. For $r > 0$ sufficiently small the distance sphere $S_r(p) = \{ x \in M : d(p, x) = r \}$ is contained in $U$, is compact, and agrees with the geodesic sphere of radius $r$ centered at $p$. Then, $\rho_C$ restricted to $S_r(p)$ achieves a minimum at some point $q$, say. Let $c$ be the unique minimizing geodesic from $q$ to $p$. From the choice of $q$ on $S_r(p)$, and simple distance function considerations, one has for each $x$ on $c$

$$d(C, q) + d(q, x) = d(C, x) ,$$

where $d(C, x) = \rho_C(x)$. Since $c$ is minimizing on each segment, Equation (4.1) implies that $c$ is a $C$-minimizing segment. \hfill $\Box$

Each $C$-minimizing segment $\gamma: I \to S$ is contained in a maximal (with respect to the size of the interval of definition) $C$-minimizing segment and from now on we assume that all $C$-minimizing segments are defined on their maximal domain. We say that a $C$-minimizing segment $\gamma: I \to S$ has a *cut point* iff its interval of definition is of the form $[a, b]$ or $(a, b]$ with $b < \infty$, in which case $p = \gamma(b)$ is defined to be the cut point. A $C$-minimizing segment can fail to have a cut point either because its domain is unbounded, i.e. of the form $[a, \infty)$ or $(a, \infty)$, or because the domain is bounded, say $(a, b)$ but the limit $\lim_{t \uparrow b} \gamma(t)$ does not exist in $S$. The later condition can not arise when $S$ is complete. When $S$ is complete the domains of $C$-minimizing segments are all of the form $[0, b]$ or $[0, \infty)$.

The collection of all cut points is the *cut locus* of $C$ in $S$ and denoted by $\text{Cut}_C$. The cut locus $\text{Cut}_C$ is a subset of $S \setminus C$, and the definition here of $\text{Cut}_C$ agrees with the usual definition when $S$ is complete. For any $p \in S \setminus C$ let $N_C(p)$ be the number of $C$-minimizing segments on which $p$ lies. Then for all $p \in S \setminus C$ we have $N_C(p) \geq 1$ and it is known that if $N_C(p) \geq 2$ then $p \in \text{Cut}_C$. For $p \in S \setminus C$ let

$$M_p := \{ -\gamma'(\rho_C(p)) : \gamma \text{ is a } C\text{-minimizing segment and } \gamma(\rho_C(p)) = p \}$$

be the set of the unit vectors at $p$ which are tangent to $C$-minimizing segments and which point toward $C$. Then the number of vectors in $M_p$ is just $N_C(p)$.

Let $M = S \times (\mathbb{R} \times [0, \infty))$ and give $M$ the Lorentzian metric $g = h - dt^2$. Let $\mathcal{H}$ be the graph of $-\rho_C$ in $M$, that is

$$\mathcal{H} := \{(x, -\rho_C(x)) : x \in S \setminus C \} .$$

We leave the proof of the following to the reader.

**Proposition 9** The set $\mathcal{H}$ is a future horizon in $M$. The null generators of $\mathcal{H}$ are (up to reparameterization) the curves $s \mapsto (\gamma(s), -\rho_C(\gamma(s)))$, where $\gamma$ is $C$-minimizing segment of $S$ and $N(p, -\rho_C(p)) = N_C(p)$. The set $\mathcal{H}_{\text{end}}$ coincides with the set $\{(p, -\rho_C(p)) : p \in \text{Cut}_C \}$.

\hfill $\Box$
The theorem of Beem and Królak [2] that a point \( p \) of a horizon is differentiable if and only if \( N(p) = 1 \) implies the Riemannian result:

**Proposition 10** With notation as above, the point \( p \in S \setminus C \) is a differentiable point of the distance function \( \rho_C \) if and only if \( N_C(p) = 1 \). \( \square \)

**Remark 11** While to best of our knowledge this result has not appeared in the literature on the regularity of Riemannian distance functions, it would be surprising if it were not known, at least in the case of of complete manifolds, to experts. It can also be deduced from general facts about the Clarke differential in non-smooth analysis. Explicitly, it follows from [6, Thm 2.1 (4) p. 251], a result about the generalized gradients of functions that are pointwise minimums of families of smooth functions with appropriate Hessian bounds, that the Clarke differential of \( \rho_C \) at \( x \in N \setminus C \) is

\[
\partial \rho_C(x) = \text{convex hull of } \{ -\langle u, \cdot \rangle : u \in \mathcal{M}_x \}
\]

(When \( S \) is Euclidean space this is [10, Lemma 4.2 pp. 1037–1038]. The extension to complete Riemannian manifolds is not hard.) The function \( \rho_C \) is semi-convex and a semi-convex function is differentiable at \( x \) if and only its Clarke differential at \( x \) is a singleton\(^4\). Therefore \( \rho_C \) is differentiable at \( x \) if and only if \( N_C(x) = 1 \). It is also possible to carry out a proof of the Beem and Królak result along these lines.

In [5] horizons in Lorentzian manifolds are constructed that are non-differentiable on a dense set. Another family of such examples, possessing genericity properties, is given in [3]. When translated into Riemannian terms the examples of [5] imply:

**Proposition 12** There exists a closed Lipschitz curve \( C \subset \mathbb{R}^2 \) such that its distance function \( \rho_C \) is non-differentiable on a dense subset of the set \( \rho_C \leq 1 \) of the unbounded component of \( \mathbb{R}^2 \setminus C \). \( \square \)

In both [3, 5] it is shown how to obtain higher dimensional examples.

Theorem 1 implies

**Proposition 13** If \( C \) is a closed set in an \( n \)-dimensional Riemannian manifold \((S,h)\), then \( \delta^{n}_H(\text{Cut}_C) = 0 \). \( \square \)

When \( C \) is a smooth submanifold of \( S \) (for example when \( C \) is a point) and the manifold \((S,h)\) is complete then a recent result of Itoh and Tanaka [14, Thm. B p. 22] implies that \( \text{Cut}_C \) has Hausdorff dimension at most \( n - 1 \). (When \( S \) is two dimensional and \( C \) is a point this had been done earlier by Hebda [11] and Itoh [13].) However for arbitrary closed sets the question of the Hausdorff dimension of \( \text{Cut}_C \) is open. In particular it is not known if there is a closed subset \( C \) of the Euclidean plane \( \mathbb{R}^2 \), with its usual metric, so that the Hausdorff dimension of \( \text{Cut}_C \) is 2. (Proposition 13 implies \( \delta^2(\text{Cut}_C) = 0 \), but this does not rule out the possibility that the Hausdorff dimension is 2.)

If \( M = S \times (-\infty,0) \) is given as its auxiliary Riemannian metric \( \sigma = h + dt^2 \), then the set of semi-tangents to \( \mathfrak{T} \) at \( p = (x,-\rho_C(x)) \) is \( N^+_p = \{(2^{-1/2}u,2^{-1/2}\partial/\partial t) : u \in \mathcal{M}_x \} \). Set

\[
\text{Cut}_C[k] := \{ x \in S \setminus C : \dim \text{Span}\{(u,\partial/\partial t) : u \in \mathcal{M}_x \} \geq k \}.
\]

As in the introduction \( \{ x \in S \setminus C : N_C(p) \geq k \} \subseteq \text{Cut}_C[k] \) and equality holds if \( 1 \leq k \leq 3 \). Note for \( k \geq 2 \) that \( \text{Cut}_C[k] \subset \text{Cut}_C \), while for \( k = 1 \) we have \( \text{Cut}_C[1] = S \setminus C \). The set \( \{ x \in N \setminus C : N_C(x) \geq 2 \} = \text{Cut}_C[2] \) is the strict cut locus and for some special choices of \( C \), for example a point or a submanifold, its structure has been studied by several authors (cf. [11, 14] and the references therein).

\(^4\)The general semi-convex case reduces to the case of convex functions. For a convex function the Clarke differential is the sub-differential in the sense of convex analysis [7, Prop 2.2.7 p. 36] and a convex function is differentiable at point if and only if its sub-differential is a singleton.
Using that the epi-graph of a distance function has locally positive reach it follows from results of Federer [8, Remark 4.15 (3) p. 447] that each set \( \text{Cut}_C[k] \) is countable rectifiable of dimension \( n+1-k \). Theorem 2 allows us to refine this to \( C^2 \) rectifiability.

**Proposition 14** For \( 1 \leq k \leq n+1 \) the set \( \text{Cut}_C[k] \) is a \( C^2 \) rectifiable set of dimension \( n+1-k \). Therefore \( \text{Cut}_C[k] \) has Hausdorff dimension \( \leq n+1-k \). \( \square \)

For each \( r > 0 \) let \( \tau_r(C) := \{ p \in S : \rho_C(p) = r \} \) be the tube of radius \( r \) about \( C \). In general these tubes can have singularities and need not be topological hypersurfaces in \( S \). We now look at what the Riemannian versions of Proposition 3.1, Proposition 3.5, Theorem 5.1 and Theorem 5.6 of [4].

Let \( \rho_C : S \rightarrow [0, \infty) \) be the function \( \rho_C \) centered at \( p \) the tube function \( \rho_C \) has second order Taylor expansion

\[
\rho_C = \rho_C(p) + d\rho_C(p)x + \frac{1}{2} D^2\rho_C(p)(x,x) + o(|x|^2)
\]

where \( x = (x^1, \ldots, x^n) \), \( d\rho_C(p) \) is a covector at \( p \) and \( D^2\rho_C(p) : T_p(S) \times T_p(S) \rightarrow \mathbb{R} \) is a symmetric bilinear form. Denote by \( S_{\text{All}} \) the set of Alexandrov points of \( \rho_C \). At points \( p \in S_{\text{All}} \) the function \( \rho_C \) is differentiable and therefore the discussion above yields that \( N_C(p) = 1 \) and that \( d\rho_C(p) = -\langle u, \cdot \rangle \) where \( u \in M_p \). If \( p \in S_{\text{All}} \) and \( r = \rho_C(p) \) then the level set \( \tau_r(C) \) has a well defined tangent space \( T_p(\tau_r(C)) := \{ X \in T_pS : d\rho_C(p)X = 0 \} \) and a well defined second fundamental form \( II \) at \( p \) given by

\[
II_p(X,Y) = -D^2\rho_C(p)(X,Y) \quad \text{for} \quad X,Y \in T_p(\tau_r(C)).
\]

Let \( A_p : T_p(\tau_r(C)) \rightarrow T_p(\tau_r(C)) \) be the corresponding Weingarten map defined by

\[
\langle A_pX,Y \rangle := II_p(X,Y) \quad \text{for} \quad X,Y \in T_p(\tau_r(C)).
\]

That is \( A_p \) is the tensor of type \((1,1)\) corresponding to the tensor \( II \) of type \((0,2)\) and \( A_p \) is a self-adjoint linear map. With the choice of signs here, when \( S = \mathbb{R}^n \) and \( C \) is the origin (so that \( \tau_r(C) \) is the sphere of radius \( r \)) for \( p \in \tau_r(C) \) we have \( A_p = -\frac{1}{r}I \). Let the Riemannian connection on \( S \) be denoted by \( \nabla \) and let \( R \) be the curvature tensor of \( S \) with signs chosen so that \( R(X,Y)Z = (\nabla_X \nabla_Y - \nabla_Y \nabla_X - \nabla_{[X,Y]})Z \).

For \( U \in T_pM \) define a linear map \( R_U : T_pS \rightarrow T_pS \) be \( R_U X = R(X,U)U \). The following summarizes the Riemannian versions of Proposition 3.1, Proposition 3.5, Theorem 5.1 and Theorem 5.6 of [4].

**Theorem 15** Let \( \gamma : I \rightarrow S \) by a \( C \)-minimizing segment with \( \gamma(0) \in C \). If \( \gamma(t_0) \in S_{\text{All}} \) for some \( t_0 \in I \), then \( \gamma(t) \in S_{\text{All}} \) for all \( t \in I_0 := \{ t_0 \} \cup (I \cap [t_0, \infty)) \) (where \( J^o \) is the interior of \( J \subset \mathbb{R} \)). The Weingarten maps \( A_{\gamma(t)} \) of the tubes \( \tau_{\rho_C(\gamma(t))}(C) \) vary smoothly on the interval \( I_0 \) and satisfy the usual Riccati equation for parallel hypersurfaces:

\[
\nabla_{\dot{\gamma}} A_{\gamma(t)} = A^2_{\gamma(t)} + R_{\gamma(t)}.
\]

Moreover for all \( r \in (0, \infty) \) the tube \( \tau_r(C) \) has locally finite \( 5^{n-1} \)-dimensional measure and for almost all \( r \in (0, \infty) \) there is a set \( P \subset \tau_r(C) \) with \( 5^{n-1}(P) = 0 \) so that every \( C \)-minimizing segment \( \gamma : I \rightarrow S \) which meets \( \tau_r(C) \setminus P \) will have \( \gamma(t) \in S_{\text{All}} \) for \( t \in I^o \). \( \square \)

In the terminology of [4] “Alexandrov points propagate to the past along generators” of horizons. In the Riemannian setting Alexandrov points of a distance function \( \rho_C \) propagate away from \( C \) along \( C \)-minimizing segments. The last sentence of Theorem 15 implies loosely that almost every \( C \)-minimizing segment is an Alexandrov segment in the sense that all of its points other than its endpoints are in \( S_{\text{All}} \).
