Abstract

The aim of this paper is to study properties of sequences that are recursively defined by a linear equation and their applications to the truncated moment problem in connection with the problem of subnormal completion of the truncated weighted shifts. Special cases are considered and some classical results due to StampfliCurto and Fialkow are recovered using elementary techniques.

1 Introduction.

Let $a_0, a_1, \ldots, a_{r-1}$ ($r \geq 2$) be some fixed real numbers with $a_{r-1} \neq 0$ and consider the sequence $V = \{V_n\}_{n \geq 0}$ defined by the following linear recurrence relation of order $r$:

$$V_{n+1} = a_0 V_n + a_1 V_{n-1} + \cdots + a_{r-1} V_{n-r+1}, \quad \text{for all } n \geq r - 1,$$

where $V_0, V_1, \ldots, V_{r-1}$ are specified by the initial conditions. Such sequences are largely studied in the literature, generally called $r$–generalized Fibonacci sequences (see [6] and [8] for example). We shall refer to them in the sequel as sequences (1).

Let $\{V_n\}_{0 \leq n \leq p} \Gamma$ where $p \leq +\infty \Gamma$ be a sequence of real numbers and $K$ be a compact subset of $\mathbb{R}$. The $K$-moment problem associated to $\{V_n\}_{0 \leq n \leq p}$ consists of finding a positive Borel measure $\mu$ such that

$$V_n = \int_K \psi^d \mu(t), \quad \text{for all } n (0 \leq n \leq p) \text{ and } \text{Supp}(\mu) \subset K,$$

where $\text{Supp}(\mu)$ is the support of $\mu$. A measure $\mu$ satisfying (2) is called a generating measure of the sequence $\{V_n\}_{0 \leq n \leq p} \Gamma$. A positive generating measure is called a representing measure (see [3] and [4]). For $p = +\infty \Gamma$ the problem (2) is called the full $K$-moment problem (see [1] for example). When $p < +\infty \Gamma$ the problem (2) is called the truncated $K$-moment problem (see [3] and [7]).

Consider the classical separable Hilbert space $\mathcal{H} = l^2(\mathbb{Z}_+)$ and $\{e_n\}_{n \geq 0}$ its orthonormal basis. Let $\alpha = \{\alpha_n\}_{n \geq 0}$ be a bounded sequence of nonnegative real numbers. Let $W_\alpha$ be the bounded operator of $\mathcal{H} = l^2(\mathbb{Z}_+)$ defined by $W_\alpha e_n = \alpha_n e_{n+1}$. Set $\{V_n\}_{n \geq 0} \Gamma$ where $V_n = \alpha_{n-1}^2 \cdots \alpha_0^2$ $(n \geq 1)$ and $V_0 > 0 \Gamma$ the sequence of moments associated to $W_\alpha$. By Berger’s theorem $W_\alpha$ is a subnormal operator if and only if there exists a nonnegative Borel measure $\mu \Gamma$ that is called a representing measure of $\{V_n\}_{n \geq 0} \Gamma$ with $\text{supp}(\mu) \subset [0, \|W_\alpha\|^2]$ and such that

$$V_n = \int_0^\infty t^n \psi^d \mu(t), \quad \text{for all } n \geq 0,$$

where $\|W_\alpha\| = \sup_{n \geq 0} \alpha_n$. Hence the moment problem and subnormal weighted shifts are closely related. A weighted shift $W_\alpha$ such that $\{V_n\}_{n \geq 0}$ is a sequence (1) is called a recursively generated weighted shift. It is known that every weighted shift is norm-limit of recursively generated weighted shifts. For further information we refer to [2] and [4] and [5] and [7] for example.

We characterize sequences (1) that are moment sequences in terms of their minimal polynomial and give some generalisations of results due to R. Curto and L. Fialkow. In the last section we apply our technique to recover easily some results due to Stampilj.

2 Sequences (1) and Moment Problem.

2.1 Minimal polynomial.

Let $V = \{V_n\}_{n \geq 0}$ be a sequence (1). The polynomial $P(x) = x^r - a_0 x^{r-1} - \cdots - a_{r-2} x - a_{r-1}$ is called a characteristic polynomial associated to $\{V_n\}_{n \geq 0}$. A sequence (1) can be defined in
various ways using different characteristic polynomials as shown in the following example.

Set \( V_n = n + 1 \Gamma \) then \( \{V_n\}_{n \geq 0} \) satisfies the following recursive relations

\[
V_{n+1} = V_n + V_{n-1} - V_{n-2},
\]

for \( V_0 = 1, V_1 = 2, V_2 = 3 \) and

\[
V_{n+1} = V_n + \frac{1}{2}(V_{n-1} - V_{n-2} + V_{n-3} - V_{n-4}),
\]

for \( V_0 = 1, V_1 = 2, V_2 = 3, V_3 = 4, V_4 = 5. \)

Hence \( P_1(X) = X^3 - X^2 - X + 1 \) and \( P_2(X) = X^5 - X^4 - \frac{1}{2}X^3 + \frac{1}{2}X^2 - \frac{1}{2}X + \frac{1}{2} \) are characteristic polynomials for the sequence \( \{V_n\}_{n \geq 0} \).

Let \( P_V \) be the set of characteristic polynomial associated to the sequence \( V = \{V_n\}_{n \geq 0} \).

**Proposition 2.1** For every sequence \( V = \{V_n\}_{n \geq 0} \) given by (1), there exists a unique characteristic polynomial \( P_V \in P_V \) with minimal degree. Moreover, every \( P \in P_V \) is a multiple of \( P_V \).

**Proof.** It is suffice to prove the second assertion of our proposition. Set \( P(X) = \prod_{i=1}^{r} (X - \lambda_i)^{n_i} \) for \( P \in P_V \). By the Binet formula we get

\[
V_n = \sum_{i=1}^{r_v} \sum_{j=1}^{k_i} c_{i,j} \lambda_i^n (c_{i,k_i} \neq 0).
\]

The polynomial \( P_V(X) = \prod_{i=1}^{r_v} (X - \lambda_i)^{k_i} \) is a characteristic polynomial for \( V = \{V_n\}_{n \geq 0} \). On the other hand \( \lambda_i \) is a zero of order at least \( k_i \) for every characteristic polynomial for \( \{V_n\}_{n \geq 0} \). Hence \( P_V \) provides a positive answer to the proposition. \( \square \)

**Definition 2.2** Let \( V = \{V_n\}_{n \geq 0} \) be a sequence (1). The polynomial \( P_V(X) = X^r - a_0 X^{r-1} - a_1 X^{r-2} - \ldots - a_{r-1} \) is called the minimal polynomial associated to \( \{V_n\}_{n \geq 0} \). The sequence \( \{V_n\}_{n \geq 0} \) is said to be of order \( r \).

**Remark 2.3**

1. The minimal polynomial obtained from the Binet formula of sequence (1) coincides with the generating function of [3], which is obtained by computing the rank of the Hankel matrix associated with \( \{V_n\}_{n \geq 0} \). Polynomials are the basic tools for constructing the \( r \)-atomic representing measure for the sequence \( \{V_n\}_{n \geq 0} \).

2. As shown in proposition 2.1, the minimal polynomial is a factor of any characteristic polynomials that depend only on the initial conditions. Hence it can be computed by ‘testing’ equation (1) for a finite number of characteristic polynomial’s factors.
2.2 Generating measure and minimal polynomial.

**Proposition 2.4** Let $V = \{V_n\}_{n \geq 0}$ be a sequence (1). Then $\{V_n\}_{n \geq 0}$ admits a generating measure $\mu$ if and only if $P_V$ has distinct real roots. Moreover, $\text{Supp}(\mu) = Z(P_V)$.

**Proof.** Set $P_V(X) = \prod_{i=0}^{r-1} (X - \lambda_i)$ with $\lambda_0 < \ldots < \lambda_{r-1}$, then the Binet formula implies that

$$V_n = \rho_0 \lambda^n_0 + \cdots + \rho_{r-1} \lambda^n_{r-1}, \text{ for any } n \geq 0,$$

(3)

where $\rho_0, \ldots, \rho_{r-1}$ are nonzero real numbers derived from the following system of $r$ linear equations $\rho_0 \lambda^n_0 + \cdots + \rho_{r-1} \lambda^n_{r-1} = V_n \Gamma n = 0, 1, \ldots, r - 1$ (see [6] for example). Consider the Borelean $r$–atomic measure $\mu$ given by $\mu = \sum_{j=0}^{r-1} \rho_j \delta_{\lambda_j}$ on the interval $[\lambda_0, \lambda_{r-1}]$. From expression (3) we derive that

$$V_n = \int_{\lambda_0}^{\lambda_{r-1}} \theta^n d\mu(t), \text{ for any } n \geq 0.$$

Conversely suppose that $\mu$ is a generating measure associated to $\{V_n\}_{n \geq 0}$ and $P \in \mathcal{P}_V$. Easy computations give $P \mu = 0 \Gamma$ which assert that $\text{Supp}(\mu) \subseteq Z(P) = \{\lambda_0, \ldots, \lambda_n\}$. Set $\mu = \sum_{j=0}^{r-1} \rho_j \delta_{\lambda_j} \Gamma$ where $\rho_j$ are nonzero real numbers. Hence $V_n = \rho_0 \lambda^n_0 + \cdots + \rho_{r-1} \lambda^n_{r-1}$ $(\rho_i \neq 0)$. We obtain $P_V$ by setting $P_V(X) = \prod_{i=0}^{r-1} (X - \lambda_i) \Gamma$ which is the minimal polynomial of $\{V_n\}_{n \geq 0}$. □

**Remark 2.5** Proposition 2.4 is valid without assuming that the polynomial $P_V$ has real roots, however in the subnormal completion problem this will be the case.

In the following we consider sequences (1) that are given by $P_V$ with distinct roots. Let $\mu$ be a nonnegative measure solution of the moment problem associated to the initial conditions $\{V_n\}_{0 \leq n \leq r-1}$ of the sequence (1). Then from properties of the truncated moment problem we derive that the Hankel matrix $H(r) = (V_{i+j})_{0 \leq i, j \leq r}$ is nonnegative (see [2]Γ[3]Γ[7] for example).

On the other hand suppose that the Hankel matrix $H(r) = (V_{i+j})_{0 \leq i, j \leq r}$ is nonnegative. Expression (3) means that $\mu$ is an interpolating $r$–atomic measure of the sequence $\gamma = (\gamma_{i,j})_{0 \leq i, j \leq r} \Gamma$ where $\gamma_{i,j} = V_{i+j}$. Thus Propositions 3.8Γ3.17 of [3] and Proposition 3 of [7] allow us to derive that $\mu$ is a nonnegative measure. Hence we have the following result

**Theorem 2.6** Let $V = \{V_n\}_{n \geq 0}$ be a sequence (1) and $P_V(X) = \prod_{i=0}^{r-1} (X - \lambda_i)$ be its minimal polynomial, with $\lambda_0 < \ldots < \lambda_{r-1}$ . Then, there exists a nonnegative representing measure $\mu$ for $\{V_n\}_{n \geq 0}$ if and only if the Hankel matrix $H(r) = (V_{i+j})_{0 \leq i, j \leq r}$ is nonnegative.

3 Application to subnormal completion of weighted truncated Shifs.

We interpret Theorem 2.6 in terms of subnormality of $W_\alpha$ that is close to the positivity of Hankel matrices (see [2]Γ[4]Γ[3] and [7] for example). We derive the following property
Theorem 3.1 Let \( V = \{V_n\}_{n \geq 0} \) be a positive sequence (1) and \( P_V(X) = \prod_{i=0}^{r-1} (X - \lambda_i) \) be its minimal polynomial with \( \lambda_0 < \cdots < \lambda_{r-1} \). Let \( \alpha = (\alpha_n)_{n \geq 0} \) be the sequence defined by \( \alpha_n^2 = \frac{V_{n+1}}{V_n} \). Then the operator \( W_\alpha \) is subnormal if and only if the Hankel matrix \( H(r) = (V_{i+j})_{0 \leq i, j \leq r} \) is nonnegative.

Proof. From Theorem 2.6 we derive that the support of the positive measure \( \mu \) is a subset of the interval \([\lambda_0, \lambda_{r-1}]\). Following the same proof of Theorem 2.6 and using Proposition 3.8 of [3] and Proposition 3 of [7] we can derive that \( H(r-1) \geq 0 \) if and only if \( W_\alpha \) is subnormal operator. Hence from Theorem 3.2 of [2] \( W_\alpha \) is subnormal if and only if \( H(k) \geq 0 \) for any \( k \geq 0 \). Thus we have the following proposition:

Proposition 3.2 Let \( V = \{V_n\}_{n \geq 0} \) be a positive sequence (1). Suppose that \( P_V(X) = \prod_{i=0}^{r-1} (X - \lambda_i) \) is its minimal polynomial. Suppose that \( 0 < \lambda_0 < \cdots < \lambda_{r-1} \), then the following are equivalent,

(i) \( H(r-1) \geq 0 \);

(ii) \( H(r) \geq 0 \);

(iii) \( H(k) \geq 0 \) for any \( k \geq 0 \).

Proposition 3.2 allows us to derive the following relation between subnormality and k-hyponormality in the case of sequences (1).

Proposition 3.3 Let \( \{V_n\}_{n \geq 0} \) be a positive sequence (1). Suppose that the characteristic roots \( \lambda_0, \cdots, \lambda_{r-1} \) are simple and positive. Let \( \alpha = (\alpha_n)_{n \geq 0} \) be the sequence defined by \( \alpha_n^2 = \frac{V_{n+1}}{V_n} \). Then the following are equivalent,

(i) \( W_\alpha \) is subnormal;

(ii) \( W_\alpha \) is k-hyponormal;

(iii) There exists \( k_0 \geq r-1 \) such that \( W_\alpha \) is \( k_0 \)-hyponormal.

Proof. Implications (i) \( \Rightarrow \) (ii) and (ii) \( \Rightarrow \) (iii) follow from [2]. Let us establish (iii) \( \Rightarrow \) (i). Suppose that there exists \( k_0 \geq r-1 \) such that \( H(k_0) \geq 0 \). Then Proposition 3.2 implies that \( H(r-1) \geq 0 \). Hence \( W_\alpha \) is subnormal. \( \square \)

4 Special Cases.

4.1 case \( n = 2 \) and \( n = 3 \).

Let \( \{V_n\}_{n \geq 0} \) be a sequence (1) such that \( V_{n+1} = a_0 V_n + a_1 V_{n-1} \) and \( V_0 = 1, V_1 \) are given. The characteristic polynomial is \( P(X) = X^2 - a_0 X - a_1 \). Suppose that \( \{V_n\}_{n \geq 0} \) is a moment sequence associated to a measure \( \mu \). A simple use of the Cauchy-Schwartz inequality gives \( V_2 = a_0 V_1 + a_1 \geq V_1^2 \). Hence \( P(V_1) \leq 0 \). On the other hand if \( P(V_1) \leq 0 \) we get \( V_1 = \rho_1 \lambda_1 + \rho_2 \lambda_2 \Gamma \) where
\[ \lambda_1 = \frac{a_0 - \sqrt{a_0^2 + 4a_1}}{2}, \lambda_2 = \frac{a_0 + \sqrt{a_0^2 + 4a_1}}{2} \] are the distinct real roots of \( P \) and \( \rho_1, \rho_2 \) are nonnegative real numbers such that \( \rho_1 + \rho_2 = 1 \). Thus \( \{V_n\}_{n \geq 0} \) is a moment sequence associated to the nonnegative measure \( \mu = \rho_1 \delta_{\lambda_1} + \rho_2 \delta_{\lambda_2} \). Hence \( \Gamma \)

**Proposition 4.1** A sequence \( \{V_n\}_{n \geq 0} \) such that \( V_0 = 1, V_1 \) are given and \( V_{n+1} = a_0 V_n + a_1 V_{n-1} \) is a moment sequence if and only if \( P(V_1) \leq 0 \).

**Remark 4.2** 1. For given \( V_1 \geq 0 \), we have \( P(V_1) \leq 0 \) if and only if \( \frac{a_0 - \sqrt{a_0^2 + 4a_1}}{2} \leq V_1 \leq \frac{a_0 + \sqrt{a_0^2 + 4a_1}}{2} \), that is easy to obtain.

2. By writing \( \gamma_1^2 = \frac{V_1}{V_2} \) we get \( P(V_1) \leq 0 \) if and only if \( \gamma_0 \leq \gamma_1 \). Hence for \( 0 < \gamma_0 < \gamma_1 \), we can construct \( \gamma_n \) (\( \gamma_n^2 = \frac{V_{n+1}}{V_n} \)) such that \( W_\alpha \) is subnormal and the result of Stampfl is recovered (see [9]).

3. Consider \( V_{n+1} = a_0 V_n + a_1 V_{n-1} \) for \( n = 1, 2 \). Thus \( a_0 = \frac{V_2 V_1 - V_3}{V_2^2 - V_1^2} \) and \( a_1 = \frac{V_2^2 - V_1^2}{V_2^2 - V_1^2} \). As \( V_1 = \gamma_0^2, V_2 = \gamma_0^2 \gamma_1^2 \) and \( V_3 = \gamma_0^2 \gamma_1^2 \gamma_2^2 \) we get \( a_0 = \gamma_1^2 \gamma_2^2 \gamma_3^2 \gamma_0^2 \) and \( a_1 = (\gamma_0 \gamma_1)^2 \gamma_2^2 \gamma_3^2 \gamma_0^2 \), as it was shown in [2].

In the following proposition we characterize sequences (1) of order \( r = 3 \) that give moment sequences. Given \( V_0 = 1, V_1 \) and \( V_2 \) nonnegative real numbers under which conditions a sequence (1) such that \( V_{n+1} = a_0 V_n + a_1 V_{n-1} + a_2 V_{n-2} \) (\( n \geq 3 \)) is a moment sequence. Let \( P(X) = X^3 - a_0 X^2 - a_1 X - a_2 \) be its minimal characteristic polynomial and suppose that \( \mu \) is a generating nonnegative measure \( \Gamma \) where \( \{\lambda_0, \lambda_1, \lambda_2\} = Z(P) \) (\( \lambda_0 < \lambda_1 < \lambda_2 \)) and \( \rho_0, \rho_1, \rho_2 \) are solutions of the following system of equations:

\[
\begin{cases}
\rho_0 + \rho_1 + \rho_2 = 1, \\
\rho_0 \lambda_0 + \rho_1 \lambda_1 + \rho_2 \lambda_2 = V_1, \\
\rho_0 \lambda_0^2 + \rho_1 \lambda_1^2 + \rho_2 \lambda_2^2 = V_2.
\end{cases}
\]

Then \( \rho_0, \rho_1 \) and \( \rho_2 \) are given by

\[
\rho_0 = \frac{V_2 - V_1 (\lambda_1 + \lambda_2) + \lambda_2 \lambda_0}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_0)(\lambda_1 - \lambda_0)}, \quad \rho_1 = \frac{-V_2 + V_1 (\lambda_1 + \lambda_2) - \lambda_2 \lambda_0}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_0)(\lambda_1 - \lambda_0)}, \quad \rho_2 = \frac{V_2 - V_1 (\lambda_0 + \lambda_1) + \lambda_0 \lambda_1}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_0)(\lambda_1 - \lambda_0)}.
\]

Hence the following result holds:

**Proposition 4.3** Given \( \{V_n\}_{n \geq 0} \) a sequence (1) with initial condition \( V_0 = 1, V_1, V_2 \) and minimal polynomial \( P(X) = (X - \lambda_0)(X - \lambda_1)(X - \lambda_2) \). Then \( \{V_n\}_{n \geq 0} \) is a moment sequence for a nonnegative measure if and only if

\[
\begin{cases}
V_2 - V_1 (\lambda_1 + \lambda_2) + \lambda_1 \lambda_2 \geq 0, \\
-2V_2 + V_1 (\lambda_1 + \lambda_2) - \lambda_0 \lambda_2 \geq 0, \\
V_2 - V_1 (\lambda_0 + \lambda_1) + \lambda_0 \lambda_1 \geq 0.
\end{cases}
\]

**4.2 case \( n = 4 \).**

Given \( 0 \leq \gamma_0 \leq \gamma_1 \leq ... \leq \gamma_n \). A subnormal completion weighted shift \( W_\alpha \) of \( (\gamma_0, \gamma_1, ..., \gamma_n) \) is a weighted shift \( W_\alpha \Gamma \) where \( \alpha = (\alpha_0, ..., \alpha_n, ...) \) so that \( \alpha_i = \gamma_i \) (\( 0 \leq i \leq n \)). Let \( W(\gamma_0, ..., \gamma_n) \) be the set of all subnormal completion weighted shifts of \( (\gamma_0, ..., \gamma_n) \) and

\[
\Gamma(\gamma_0, ..., \gamma_n) = \inf\{\alpha_{n+1}, W_\alpha \in W(\gamma_0, ..., \gamma_n)\}.
\]
For $0 \leq \gamma_0 \leq \gamma_1$ a direct computation using the norm-density of recursive weighted shifts $\Gamma$ gives $\Gamma(\gamma_0, \gamma_1) = \gamma_1$. We derive that every sequence $\{\gamma_0, \gamma_1, \gamma_2\} \Gamma$ where $0 \leq \gamma_0 \leq \gamma_1 \leq \gamma_2 \Gamma$ admits a subnormal completion weighted shift associated to a sequence (1) of order $r$.

As shown in [9] a sequence $\gamma_0 \leq \gamma_1 \leq \gamma_2 \leq \gamma_3$ may have no subnormal completion weighted shift. We characterize those sequences that admit a subnormal completion weighted shift by computing $\Gamma(\gamma_0, \gamma_1, \gamma_2)$.

**Proposition 4.4** Given $0 \leq \gamma_0 \leq \gamma_1 \leq \gamma_2$ then

$$\Gamma(\gamma_0, \gamma_1, \gamma_2) = \frac{\gamma_1^2(\gamma_1^2 \gamma_2^2 + \gamma_4^2 - 2 \gamma_0 \gamma_2^2)}{\gamma_2^2(\gamma_1^2 - \gamma_0^2)}.$$  

In particular, the sequence $(\gamma_0, \gamma_1, \gamma_2, \gamma_3)$ admits a subnormal completion weighted shift if and only if

$$\gamma_3^2 \geq \frac{\gamma_1^2(\gamma_1^2 \gamma_2^2 + \gamma_4^2 - 2 \gamma_0 \gamma_2^2)}{\gamma_2^2(\gamma_1^2 - \gamma_0^2)}.$$  

**Proof.** By Proposition 3.2 $\gamma = (\gamma_0, \gamma_1, \gamma_2, \gamma_3)$ admits a subnormal completion weighted shift if and only if

$$\begin{pmatrix}
1 & V_1 & V_2 \\
V_1 & V_2 & V_3 \\
V_2 & V_3 & V_4
\end{pmatrix} \geq 0.$$  

Hence for $x, y$ and $z$ real numbers we get

$$\begin{pmatrix}
1 & V_1 & V_2 \\
V_1 & V_2 & V_3 \\
V_2 & V_3 & V_4
\end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} \geq 0,$$  

which leads to

$$x^2 + V_2y^2 + V_4z^2 + 2V_1xy + 2V_2xz + 2V_3yz \geq 0,$$  

for any $x \Gamma y \Gamma z$. By setting $x' = x, y' = \sqrt{V_2}y, z' = \sqrt{V_4}z, a = \frac{V_1}{\sqrt{V_2}}, b = \frac{V_2}{\sqrt{V_4}}$ and $c = \frac{V_3}{\sqrt{V_2V_4}}$ we obtain that $(x')^2 + (y')^2 + (z')^2 + 2ax'y' + 2bx'z' + 2cy'z' \geq 0 \Gamma$ for any $x', y', z'$. Hence

$$(x' + ay' + bz')^2 + (1 - a^2)(y')^2 + (1 - b^2)(z')^2 + 2(c - ab)y'z' \geq 0,$$  

for any $x', y', z'$ and so $(c - ab)^2 - (1 - a^2)(1 - b^2) \leq 0$. That is equivalent to $a^2 + b^2 + c^2 - 2abc - 1 \leq 0$. In terms of $V_1, V_2, V_3$ and $V_4$ we obtain that $V_4 \geq \frac{V_2^2 + V_3^2 - 2V_1V_2V_3}{V_2 - V_1}$ and by using our weight $\Gamma$ we get $\gamma_3^2 \geq \frac{\gamma_1^2(\gamma_1^2 \gamma_2^2 + \gamma_4^2 - 2 \gamma_0 \gamma_2^2)}{\gamma_2^2(\gamma_1^2 - \gamma_0^2)}$. □

For $\gamma_0^2 = 1, \gamma_1^2 = 2$ and $\gamma_2^2 = 3$ we obtain that $\gamma = (\gamma_0, \gamma_1, \gamma_2, \gamma_3)$ admits a subnormal completion weighted shifts if and only if $\gamma_3^2 \geq \frac{10}{3}$ as given in the example of [9].

In [9] it is also shown that for a given moment sequence $\{\gamma_n\}_{n \geq 0}$ we have $\gamma_n = \gamma_m$ whenever there exists $n_0 \geq 1$ such that $\gamma_{n_0} = \gamma_{n_0+1}$. This result can be obtained by using Proposition 4.5 in an inductive proof however sequences (1) allow us to give it in a simple way.

**Proposition 4.5** Let $\{V_n\}_{n \geq 0}$ be a moment sequence and suppose that there exists $n_0 \geq 2$ such that $\gamma_{n_0} = \gamma_{n_0+1}$, then $\gamma_n = \gamma_m$ for any $n, m \geq 1$.  

7
Proof. Let \( \{V_n\}_{n \geq 0} \) be a moment sequence and \( \{V_n\}_{0 \leq n \leq p} \) be a truncated subsequence for an arbitrary \( p \geq n_0 + 1 \). By theorem 2.6 \( \{V_n\}_{0 \leq n \leq p} \) can be extended in a recursive moment sequence (see also [3]) we can assume that \( \{V_n\}_{n \geq 0} \) is a sequence (1). Let \( \mu = \sum_{0 \leq i \leq r-1} \rho_i \delta_{\lambda_i} \) be a representing measure. Then \( \frac{V_{n_0+1}}{V_{n_0}} = \frac{V_{n_0+2}}{V_{n_0+1}} \) implies that
\[
(\sum_{0 \leq i \leq r-1} \rho_i (\lambda_i)^{n_0+1})^2 = (\sum_{0 \leq i \leq r-1} \rho_i (\lambda_i)^{n_0}) (\sum_{0 \leq i \leq r-1} \rho_i (\lambda_i)^{n_0+2}),
\]
or
\[
\sum_{0 \leq i < j \leq r-1} \rho_i \rho_j (\lambda_i \lambda_j)^{n_0+1} (\lambda_i - \lambda_j)^2 = 0,
\]
which gives \( \lambda_i = \lambda_j \) whenever \( \lambda_i, \lambda_j \neq 0 \). Thus \( V_n = \rho \lambda^n_i \) for \( n \geq 1 \) where \( \rho = \sum_{0 \leq i \leq r-1} \rho_i \). Finally
\[
(\gamma_n)^2 = \lambda_1 \text{ for all } n \geq 2.
\]
As \( p \) is arbitrary we obtain the proposition. □

Acknowledgments.

The authors would like to express their sincere gratitude to the referee for several useful and valuable suggestions that improved the presentation of the paper. Note also that the authors benifitted from the lecture of R. Curto given at CIMR 99-Rabat [2] and the fruitful discussions with G. Cassier during "Journées de Lille" January 2000.

This work has been partially supported by the Associate Scheme of the Abdus Salam International Centre for Theoretical Physics Trieste Italy. The last two authors would also like to thank Professor C.E. Chidume Mathematics Section of ICTP for his encouragement.
