(July 3, 2001)

We investigate the geometric phases and the Bargmann invariants associated with a multi-level quantum systems. In particular, we show that a full set of ‘gauge-invariant’ objects for an \( n \)-level system consists of \( n \) geometric phases and \( \frac{1}{2}(n - 1)(n - 2) \) algebraically independent 4-vertex Bargmann invariants. In the process of establishing this result we develop a canonical form for \( U(n) \) matrices which is useful in its own right. We show that the recently discovered ‘off-diagonal’ geometric phases \([ N. \text{ Manini and F. Pistolesi, Phys. Rev. Lett. 8, 3067 (2000)} \] can be completely analysed in terms of the basic building blocks developed in this work. This result liberates the off-diagonal phases from the assumption of adiabaticity used in arriving at them.

I. INTRODUCTION

The notion of geometric phase, though defined originally in the context of adiabatic, unitary and cyclic evolution \([1]\), has now come to be recognised as a direct consequence of the geometry of the complex Hilbert space and that of the associated ray space \([2]\). The quantum kinematic \([2]\) picture which has thus emerged provides a much wider setting for the notion of the geometric phase by rendering superfluous the various assumptions that attended its original discovery \([1]\), and subsequent development \([3–5]\). In particular, the requirement of cyclic evolution is no longer necessary and it becomes possible to ascribe a geometric phase to any open curve in the Hilbert space which has non-orthogonal unit vectors as its end points. Further, following the quantum kinematic approach \([6]\) one is led, in a natural way, to the intimate relationship that exists between the geometric phase and the \( n \)-vertex Bargmann invariants \([7]\) and that between the geometric phase and Hamilton’s theory of turns \([8]\). As an application of this approach the Gouy phase (the phase jump experienced by a focussed light beam as it crosses the focus), discovered over a hundred years ago, has been shown to be a four vertex Bargmann invariant \([9]\).

In the present work, we develop the quantum kinematic approach for the special case of unitary evolution of an \( n \)-level system. It turns out that, in the present context, it becomes necessary to introduce Bargmann invariants constructed out of two sets of orthonormal basis vectors. We investigate, in detail, their properties and identify and construct a full set of gauge-invariant building blocks for the \( n \)-level system. We also develop a canonical representation of \( U(n) \) matrices and bring out its relation to the Bargmann invariants. This representation has recently been shown to be extremely useful in parametrizing the Cabibbo-Kobayashi-Maskawa matrix which arises in the context of CP-violation in particle physics \([10]\).

As noted above, the geometric phase becomes undefined for those open curves in the Hilbert space which have orthogonal vectors at their ends. A recent work by Manini and Pistolesi \([11]\) addresses itself precisely to such exceptional cases. Employing the original Berry setting of adiabatic evolution for an \( n \)-level quantum system, they introduce the
II. GEOMETRIC PHASES AND BARGMANN INVARIANTS

We review very briefly the background and ingredients that go into the definition of the quantum geometric phase from the kinematic viewpoint, and then the Bargmann invariants and their properties in the generic case. Let $\mathcal{H}$ be the Hilbert space of states of some quantum system, and let $\mathcal{B}$ be the set of unit vectors in $\mathcal{H}$:

$$\mathcal{B} = \{ \psi \in \mathcal{H} \mid \| \psi \|^2 = (\psi, \psi) = 1 \} \subset \mathcal{H}. \quad (2.1)$$

The corresponding ray space (consisting of equivalence classes of unit vectors which differ from one another by phases) and projection map are written as $\mathcal{R}$ and $\pi$ respectively:

$$\pi : \mathcal{B} \rightarrow \mathcal{R} = \text{space of unit rays.} \quad (2.2)$$

To arrive at the concept of geometric phase we begin with parametrised smooth (for our purposes continuous and once piecewise differentiable) curves $\mathcal{C}$ of unit vectors, which may be pictured as strings lying in $\mathcal{B}$:

$$\mathcal{C} = \{ \psi(s) \in \mathcal{B} \mid s_1 \leq s \leq s_2 \} \subset \mathcal{B}. \quad (2.3)$$

A gauge transformation is a smooth change of phase in a parameter dependent manner at each point of such a curve $\mathcal{C}$ to lead to another $\mathcal{C'}$:

$$\mathcal{C'} = \left\{ \psi'(s) = e^{i\alpha(s)} \psi(s) \mid \psi(s) \in \mathcal{C}, \ s_1 \leq s \leq s_2 \right\} \subset \mathcal{B}. \quad (2.4)$$

Then $\mathcal{C'}$ and $\mathcal{C}$ share a common parametrised image curve $C$ in ray space:

$$\pi[C'] = \pi[C] = C \subset \mathcal{R}. \quad (2.5)$$

In general we permit $\mathcal{C}$ and even $C$ to be open curves.

The total, dynamical and geometric phases are then defined as follows as functionals of appropriate arguments:

$$\varphi_{\text{tot}}[C] = \arg \left( \psi(s_1), \psi(s_2) \right),$$

$$\varphi_{\text{dyn}}[C] = \text{Im} \int_{s_1}^{s_2} ds \left( \psi(s), \frac{d\psi(s)}{ds} \right),$$

$$\varphi_{g}[C] = \varphi_{\text{tot}}[C] - \varphi_{\text{dy}n}[C]. \quad (2.6)$$

While the first two phases are functionals of $\mathcal{C}$ and do change under a gauge transformation, the geometric phase $\varphi_{g}[C]$ is gauge-invariant, which explains why it is written as a functional of the ray space curve $C$. All three phases are, however, individually reparametrisation invariant.

Now we turn to the Bargmann invariants and their 3connection to geometric phases. Given any sequence of $n$ vectors $\psi_1, \psi_2, \ldots, \psi_n$ in $\mathcal{B}$, the corresponding $n$-vertex Bargmann invariant is

$$\Delta_n(\psi_1, \psi_2, \ldots, \psi_n) \equiv (\psi_1, \psi_2)(\psi_2, \psi_3) \ldots (\psi_{n-1}, \psi_n)(\psi_n, \psi_1). \quad (2.7)$$
Here we assume in the generic case that no two successive vectors in the sequence are mutually orthogonal. It is clear that this expression is invariant under cyclic permutations of the ψ’s, and also under independent phase changes of the individual vectors. Therefore it is actually a quantity defined at the ray space level. It turns out that the phase of \( \Delta_n(\psi_1, \psi_2, \ldots, \psi_n) \) is the geometric phase for suitably constructed closed ray space curves obtained by joining each \( \psi_j \) to the next \( \psi_{j+1} \) (and finally \( \psi_n \) to \( \psi_1 \)) by any so-called ‘null-phase curve’ [6]. A null-phase curve is a continuous ray-space curve such that for any finite connected portion of it the geometric phase vanishes. That is ‘being in phase’ in the Pancharatnam sense [13] becomes an equivalence relation on such curves. Examples of null-phase curves are ray space geodesics (with respect to the well-known Fubini-Study metric [14,15]), but the former are a much larger set than the latter [6]. It should be emphasized that whereas the Bargmann invariant (2.7) is defined once its ‘vertices’, namely the projections \( \pi(\psi_1), \pi(\psi_2), \ldots, \pi(\psi_n) \) in \( \mathcal{R} \), are given, to interpret its phase as a geometric phase requires that we join each \( \psi_j \) to the next \( \psi_{j+1} \) in some definite manner, namely by some null phase curve, resulting in an ‘n-sided’ closed figure in \( \mathcal{R} \).

It can now be seen that as far as phases are concerned, an \( n \)-vertex Bargmann invariant for \( n \geq 4 \) can be reduced to a product of \( \Delta_3 \) factors in the generic case [2], so we can regard the three-vertex Bargmann invariants as the primitive ones. For example we have

\[
\Delta_4(\psi_1, \psi_2, \psi_3, \psi_4) = \Delta_3(\psi_1, \psi_2, \psi_3) \Delta_3(\psi_1, \psi_3, \psi_4) / |(\psi_1, \psi_3)|^2,
\]

and more generally

\[
\Delta_n(\psi_1, \psi_2, \ldots, \psi_n) = \Delta_3(\psi_1, \psi_2, \psi_3) \Delta_{n-1}(\psi_1, \psi_3, \psi_4, \ldots, \psi_n) / |(\psi_1, \psi_3)|^2.
\]

Thus the geometric phases of ray space ‘triangles’, each of whose sides is a null phase curve, are primitive or irreducible phases, and all others can be built up from them additively. The purpose in mentioning this is that in the particular situation we shall be dealing with later the primitive Bargmann invariants will turn out to be \( \Delta_4 \)’s rather than \( \Delta_3 \)’s, so that situation will not be generic in the present sense.

### III. GAUGE-INvariant PHASES FOR N-LEVEL SYSTEMS

We now turn to a study of phases associated with \( n \)-level quantum systems. Thus we have an \( n \)-dimensional complex Hilbert space \( \mathcal{H}_n \) describing the pure states of the system. The unit sphere in \( \mathcal{H}_n \), and the corresponding space of unit rays, will be denoted by \( \mathcal{B}_n \) and \( \mathcal{R}_n \) respectively.

If we imagine that a time-dependent Hamiltonian (\( n \times n \) hermitian matrix) is given, then at each time its complete orthonormal set of eigenvectors defines an orthonormal basis for \( \mathcal{H}_n \). Assuming there are no degeneracies or level crossings, the eigenvalues can be arranged in, say, increasing order; and at each time this basis for \( \mathcal{H}_n \) is defined up to the freedom of phase changes in each basis vector. As time progresses this basis experiences a continuous unitary rotation.

In keeping with the approach of the previous Section, however, we will adopt a kinematic approach here as well and not assume any particular Hamiltonian to be given. Thus we imagine that for each value of a parameter \( s \) in the range \( s_1 \leq s \leq s_2 \) we have an orthonormal basis \( \psi_j(s), j = 1, 2, \ldots, n \) for \( \mathcal{H}_n \); and as \( s \) evolves this basis experiences a continuous unitary evolution. Thus we have

\[
(\psi_j(s), \psi_k(s)) = \delta_{jk}, \quad j, k = 1, 2, \ldots, n;
\]
\[
\sum_{j=1}^{n} \psi_j(s)\psi_j(s)^\dagger = \text{Id}, \quad s_1 \leq s \leq s_2.
\]

(3.1)

For ease in writing, we shall denote these vectors at the end points \( s_1 \) and \( s_2 \) as follows:

\[
\psi_j(s_1) = \psi_j, \quad \psi_j(s_2) = \phi_j.
\]

(3.2)

(The orthonormal vectors \( \psi_j \) here are not to be confused with the arguments of \( \Delta_n \) in eqn.(2.7)). Our aim is to obtain gauge-invariant expressions and phases in this context. We expect to be able to construct both geometric phases \( \varphi_g[C] \) for various \( C \), and Bargmann invariants.

For each value of the index \( j \), as \( s \) varies from \( s_1 \) to \( s_2 \), the vector \( \psi_j(s) \) traces out a particular continuous parametrised curve \( C_j \) in \( \mathcal{B}_n \):

\[
C_j = \{ \psi_j(s) \in \mathcal{B}_n \mid s_1 \leq s \leq s_2 \} \subset \mathcal{B}_n, \quad j = 1, 2, \ldots, n.
\]

(3.3)
This curve runs from $\psi_j$ to $\phi_j$. Its image is $\pi[C_j] = C_j \subset \mathcal{R}_n$, and we have $n$ distinct geometric phases:

$$
\varphi_g[C_j] = \varphi_{\text{tot}}[C_j] - \varphi_{\text{dyn}}[C_j],
\varphi_{\text{tot}}[C_j] = \arg(\psi_j, \phi_j),
\varphi_{\text{dyn}}[C_j] = \text{Im} \int_{s_1}^{s_2} ds \left( \psi_j(s), \frac{d\psi_j(s)}{ds} \right), \quad j = 1, 2, \ldots, n.
$$

(3.4)

Each of these geometric phases is unchanged under arbitrary alterations in the phase of each $\psi_j(s)$ at each parameter value $s$.

We turn next to the construction of Bargmann invariants, the vertices of which are taken from the initial orthonormal basis $\{\psi_j\}$ for $\mathcal{H}_n$ at $s = s_1$ to the moving basis $\{\psi_j(s)\}$ at a general $s$:

$$
A(s) = (a_{jk}(s)) \in U(n),
$$

$$
a_{jk}(s) = (\psi_j, \psi_k(s)), \quad s_1 \leq s \leq s_2,
$$

$$
a_{jk}(s_1) = \delta_{jk}.
$$

(4.1)

At $s = s_2$ we write $A(s_2) = A$:

$$
A = (a_{jk}),
$$

$$
a_{jk} = (\psi_j, \phi_k).
$$

(4.2)

The four-vertex Bargmann invariants of the type appearing in eqn.(3.6) are expressions involving products of matrix elements of $A$ and their complex conjugates:

$$
\Delta_4(\psi_j, \phi_k, \psi_l, \phi_m) = (\psi_j, \phi_k)(\phi_k, \psi_l)(\psi_l, \phi_m)(\phi_m, \psi_j)
$$

$$
= a_{jk}a_{kl}a_{lm}a_{jm}.
$$

(4.3)

Our problem is to determine how many algebraically independent $\Delta_4$’s there are in the generic case in so far as their phases are concerned, and to find a convenient enumeration of them. This turns out to be a somewhat intricate problem. After some preparation in this Section, the solution will be developed in the next one.

In working with $n \times n$ unitary matrices it is convenient to keep in mind the standard basis in $\mathcal{H}_n$. Then $U(n)$ is the group of unitary transformations acting on all $n$ dimensions. For $m = 1, 2, \ldots, n - 1$, we will denote by $U(m)$ the
unitary group acting on the first $m$ dimensions in $H_n$, leaving dimensions $m + 1, m + 2, \ldots, n$ unaffected. Then we have the inclusion relations (the canonical subgroup chain)

$$U(1) \subset U(2) \subset U(3) \ldots \subset U(n-1) \subset U(n).$$

(4.4)

General matrices of $U(n), U(n-1), \ldots$ will be written as $A_n, A_{n-1}, \ldots$. In a matrix $A_m \in U(m)$, the last $(n-m)$ rows and columns are trivial, with ones along the diagonal and zeroes elsewhere. (When no confusion is likely to arise, $A_m$ will also denote an unbordered $m \times m$ unitary matrix).

We will now show by a recursive argument that (almost all) elements $A_n \in U(n)$ can be expressed uniquely as $n$-fold products

$$A_n = A_n(\zeta) A_{n-1}(\eta) A_{n-2}(\xi) \ldots A_3(\beta) A_2(\alpha) A_1(\chi),$$

(4.5)

where $A_n(\zeta)$ is a special $U(n)$ element determined by an $n$-component complex unit vector $\zeta \in \mathcal{B}_n$; $A_{n-1}(\eta)$ is a special $U(n-1)$ element determined by an $(n-1)$-component complex unit vector $\eta \in \mathcal{B}_{n-1}$; and so on down to $A_2(\alpha)$ which is a special $U(2)$ element determined by a 2-component complex unit vector $\alpha \in \mathcal{B}_2$; and $A_1(\chi)$ is a phase factor belonging to $U(1)$. We are led to expect such a representation for $A_n$ by the following argument. Any vector $\zeta \in \mathcal{B}_n$ can be carried by a suitable $U(n)$ element into the $n$th vector of the standard basis, $(0, 0, \ldots, 0, 1)^T$; and the stability group of this vector is the subgroup $U(n-1)$ acting on the first $(n-1)$ dimensions in $H_n$. Thus $U(n)$ acts transitively on $\mathcal{B}_n$, and this is just the coset space $U(n)/U(n-1)$. Each coset is thus uniquely labelled by some $\zeta \in \mathcal{B}_n$. We therefore expect that a general $A_n \in U(n)$ is expressible as the product $A_n(\zeta) A_{n-1}$ where $\zeta$ is the last column in $A_n$ and $A_n(\zeta)$ is a suitably chosen coset representative. Repeating this argument $(n-1)$ times we are led to expect the representation (4.5). The counting of parameters is also just right. Remembering that $\alpha, \beta, \ldots, \xi, \eta, \zeta$ are complex unit vectors of dimensions 2, 3, \ldots, $n-2, n-1, n$ and adding the $U(1)$ phase $\chi$, the number of real independent parameters adds up to $n^2$, the dimension of $U(n)$.

We now present the argument leading to (4.5), yielding in the process the determination of $A_n(\zeta)$. Let a generic matrix $A_n = (a_{jk}) \in U(n)$ be given and let its last $(n^{th})$ column be $\zeta$:

$$a_{jn} = \zeta_j, \quad j = 1, 2, \ldots, n.$$

(4.6)

Multiplying $A_n$ by an $A_{n-1}$ on the right leaves this column unchanged. We choose $A_{n-1}$ so as to bring the $n^{th}$ row of $A_n$ to a particularly simple form (for ease in writing we keep using $A_n$ and $a_{jk}$ for the $U(n)$ element obtained at each successive stage of the argument):

$$a_{nk} = 0, \quad k = 1, 2, \ldots, n-2;$$

$$a_{n,n-1} = \text{real positive}$$

$$= (1 - |\zeta_n|^2)^{1/2}.$$

(4.7)

The $A_{n-1}$ used here is arbitrary upto an $A_{n-2}$ factor on its right. Having simplified the $n^{th}$ row of $A_n$ in this way, we can determine all the other elements in the $(n-1)^{th}$ column by imposing orthogonality of rows 1, 2, \ldots, $n-1$ to row $n$:

$$a_{n,n-1}a_{j,n-1} = -\zeta_n^* \zeta_j, \quad j = 1, 2, \ldots, n-1.$$

(4.8)

At this point the last two columns and the last row of $A_n$ are known in terms of $\zeta$.

We next use the freedom in choice of $A_{n-1}$ mentioned above and multiply $A_n$ on the right by a suitable $A_{n-2}$ (unique upto an $A_{n-3}$ on its right) to bring the $(n-1)^{th}$ row of $A_n$ to a particularly simple form:

$$a_{n-1,k} = 0, \quad k = 1, 2, \ldots, n-3;$$

$$a_{n-1,n-2} = \text{real positive}$$

(4.9)

Normalising this row gives $a_{n-1,n-2}$:

$$a_{n,n-1}a_{n-1,n-2} = (1 - |\zeta_n|^2 - |\zeta_{n-1}|^2)^{1/2}.$$

(4.10)

Next we determine all the remaining elements in the $(n-2)^{th}$ column of $A_n$ by imposing orthogonality of rows 1, 2, \ldots, $n-2$ to row $(n-1)$:
\[ a_{n,n-1}^2 a_{n-1,n-2} a_{j,n-2} = -\zeta_{n-1}^* \zeta_j, \quad j = 1, 2, \ldots, n-2. \]  \hspace{1cm} (4.11)

At this point the last three columns and last two rows of \( A_n \) are known in terms of \( \zeta \).

This argument can be repeated in the way until we obtain a matrix \( A_n(\zeta) \in \overline{U}(n) \), all of whose elements are determined by the \( n \)th column \( \zeta \), namely it serves as a coset representative in the coset space \( U(n)/U(n-1) \). (In particular the last \( U(1) \) element \( A_1(\chi) \) is used to make \( a_{21} \) real positive). After some algebra we obtain the result that the matrix \( A_n(\zeta) = (a_{jk}(\zeta)) \) is uniquely determined by the conditions:

\[
\begin{align*}
& a_{jk}(\zeta) = 0, \quad j \geq k + 2; \\
& a_{j,j-1}(\zeta) = \text{real positive}, \quad j = 2, 3, \ldots, n; \\
& a_{j,n}(\zeta) = \zeta_n, \quad j = 1, 2, \ldots, n.
\end{align*}
\]

Thus \( A_n(\zeta) \) has vanishing matrix elements in the lower left hand triangular portion up to two steps below the main diagonal; nonzero matrix elements appear only one step below the main diagonal, and beyond. The explicit expressions for the nonzero matrix elements are:

\[
\begin{align*}
a_{j-j}(\zeta) &= \rho_{j-1}/\rho_j, \quad j = 2, 3, \ldots, n; \\
a_{j,k}(\zeta) &= -\zeta_{k+1}/\rho_k \rho_{k+1}, \quad j \leq k \leq n-1; \\
a_{j,n}(\zeta) &= \zeta_n, \quad j = 1, 2, \ldots, n; \\
\rho_1 &= (|\zeta_1|^2 + |\zeta_2|^2 + \cdots + |\zeta_j|^2)^{1/2} \\
&= (1 - |\zeta_{j+1}|^2 - |\zeta_{j+2}|^2 - \cdots - |\zeta_n|^2)^{1/2}. \hspace{1cm} (4.13)
\end{align*}
\]

Since the quantities \( \rho_j \) obey

\[
\rho_1 = |\zeta_1| \leq \rho_2 \leq \rho_3 \leq \cdots \leq \rho_{n-1} \leq \rho_n = 1, \hspace{1cm} (4.14)
\]

it is evident that this determination of \( A_n(\zeta) \) goes through with no problems as long as \( \zeta_1 \) is nonzero, i.e., \( \rho_1 > 0 \).

It may be helpful to give the expressions for \( A_2(\alpha) \in U(2), A_3(\beta) \in U(3) \) determined in this way, so as to see the general pattern:

\[
A_2(\alpha) = \begin{pmatrix}
-\alpha_2^* \alpha_1 \\
\alpha_1 \\
\alpha_2
\end{pmatrix}, \quad |\alpha_1|^2 + |\alpha_2|^2 = 1; \hspace{1cm} (4.15a)
\]

\[
A_3(\beta) = \begin{pmatrix}
-\beta_2^* \beta_3 \\
\beta_2 \\
\beta_3
\end{pmatrix}, \quad \rho_1 = |\beta_1|, \quad \rho_2 = (1 - |\beta_3|^2)^{1/2}. \hspace{1cm} (4.15b)
\]

We notice in passing that these are not elements of \( SU(2) \) and \( SU(3) \) respectively.

Going back to the proof of eqn.\((4.5) \), we see that it can be recursively established; and \( \chi, \alpha, \beta, \ldots, \xi, \eta, \zeta \) supply us with exactly \( n^2 \) real independent parameters for \( A_n \). Of these, the \( \frac{1}{2}n(n-1) \) independent quantities \( |\alpha_1|, |\beta_1|, |\beta_2|, \ldots, |\zeta_1|, |\zeta_2|, \ldots, |\zeta_{n-1}| \) are of the modulus type, and then there are \( \frac{1}{2}n(n+1) \) independent phases. We can display a general element \( A_n \in U(n) \), (in particular \( A \) of eqns.\((4.2) \)) in the selfevident forms

\[
A_n = A_n(\zeta, \eta, \xi, \ldots, \beta, \alpha, \chi) = A_n(\zeta)A_{n-1}, \\
A_{n-1} = A_{n-1}(\eta, \xi, \ldots, \beta, \alpha, \chi). \hspace{1cm} (4.16)
\]

We are now interested in the following operation: suppose we premultiply and post multiply \( A_n \) by two independent diagonal elements of \( U(n) \) (a ‘gauge transformation’ of \( A_n \):
\[ A_n \rightarrow A'_n = D_n(\theta_1, \theta_2, \ldots, \theta_n) A_n \quad D_n(\theta'_1, \theta'_2, \ldots, \theta'_n), \]
\[ D_n(\theta_1, \theta_2, \ldots, \theta_n) = \text{diag} \left( e^{i\theta_1}, e^{i\theta_2}, \ldots, e^{i\theta_n} \right). \]  

We would like to know: how many independent invariants can we construct out of \( A_n \) under these transformations, how many of them are phases, and how can they be captured through four-vertex Bargmann invariants? In the case of the matrix \( A \) of eqn.(4.2) the transformation (4.17) amounts to changing the phase of each \( \psi_j \) and each \( \phi_k \) independently:

\[ \psi'_j = e^{-i\phi_j} \psi_j, \]
\[ \phi'_k = e^{i\phi_k} \phi_k, \]
\[ a'_{jk} = e^{i(\theta_j + \theta'_k)} a_{jk}, \]  

and we seek an independent set of invariant expressions of the form (4.3).

First we count the expected numbers of invariants of each kind. The real dimension of \( U(n) \) is \( n^2 \). The number of independent \( \theta \)'s and \( \theta' \)'s in (4.17) is \((2n-1)\), because an overall constant phase can be attributed to either the left or the right diagonal factor. Therefore the number of real invariants in \((n-1)^2\). In the description (4.16) of a general \( A_n \in U(n) \), it is clear that under (4.17) every component of each of \( \alpha, \beta, \ldots, \zeta \) just undergoes a phase change, so the quantities \(|\alpha_1|, |\beta_1|, |\beta_2|, \ldots, |\zeta_1|, |\zeta_2|, \ldots, |\zeta_{n-1}|\) are \(2n(n-1)\) real independent modulus type invariants. Thus there must be a balance of \(\frac{1}{2}(n-1)(n-2)\) real independent phase type invariants. This is in agreement with known results [16].

We shall describe in the next Section a recursive procedure by which we can pick out \(\frac{1}{2}(n-1)(n-2)\) algebraically independent four-vector Bargmann invariants whose phases are the expected phase invariants associated with a general \( U(n) \) matrix.

V. DETERMINATION OF INDEPENDENT BARGMANN INVARIANTS

We describe first how, in a recursive manner, we can isolate the expected \(\frac{1}{2}(n-1)(n-2)\) independent gauge-invariant phases for a generic \( A_n \in U(n) \) using the parametrisation (4.5), and then turn to the choice of an equal number of independent primitive Bargmann invariants \( \Delta_4 \).

We begin with eqns.(4.5,4.16),

\[ A_n = A_n(\zeta)A_{n-1}, \]
\[ A_{n-1} = A_{n-1}(\eta)A_{n-2}(\zeta) \ldots A_2(\alpha)A_1(\chi), \]
\[ = A_{n-1}(\eta, \xi, \ldots, \alpha, \chi), \]  

(5.1)

apply diagonal matrices on the left and on the right as in eqn.(4.17), and trace the changes that occur in \( \zeta \) and in \( A_{n-1} \):

\[ A'_n = D_n(\theta_1, \theta_2, \ldots, \theta_n) A_n \quad D_n(\theta'_1, \theta'_2, \ldots, \theta'_n) \]
\[ = A_n(\zeta')A'_{n-1}. \]

(5.2)

Our aim is to compute \( \zeta' \) and \( A'_{n-1} \). Since the \( D_n \) factors are quite elementary this can be carried through as follows:

\[ A'_n = D_n(\theta_1, \theta_2, \ldots, \theta_n) A_n(\zeta) A_{n-1} D_n(\theta'_1, \theta'_2, \ldots, \theta'_n) \]
\[ = D_n(\theta_1, \theta_2, \ldots, \theta_n) A_n(\zeta) A_{n-1}(0,0,\ldots,0) D_n(\theta'_1, \theta'_2, \ldots, \theta'_n, 0) \]
\[ = D_n(\theta_1, \theta_2, \ldots, \theta_n) A_n(\zeta) D_n(0,0,\ldots,0,\theta'_n) A_{n-1}(0,0,\ldots,0,\theta'_n) A_{n-1}(\theta'_1, \theta'_2, \ldots, \theta'_{n-1}). \]

(5.3)

The product of the first three factors simplifies:

\[ D_n(\theta_1, \theta_2, \ldots, \theta_n) \quad A_n(\zeta) D_n(0,0,\ldots,0,\theta'_n) \]
\[ = D_n(\theta_1, \theta_2, \ldots, \theta_n)(a_{jk}(\zeta)) D_n(0,0,\ldots,0,\theta'_n) \]
\[ = (b_{jk}(\zeta)), \]
\[ b_{jn}(\zeta') = e^{i(\theta_j + \theta'_{n})} \zeta'_j, \]
\[ b_{jk}(\zeta) = e^{i\theta} a_{jk}(\zeta), \quad k = 1,2,\ldots, n-1. \]

(5.4)
Here the matrix elements $a_{jk}(\zeta)$ are given in eqn.(4.13), and for simplicity the $\theta$ and $\theta'$ dependences of $b_{jk}$ are left implicit. In particular, as in eqn.(4.12),

$$b_{jk}(\zeta) = 0, \quad k = 1, 2, \ldots, j - 2; \quad j = 3, 4, \ldots, n,$$

while

$$b_{j,j-1}(\zeta) = e^{i\theta_j}a_{j,j-1}(\zeta) = e^{i\theta_j}/\rho_j, \quad j = 2, 3, \ldots, n.$$

Thus the matrix $(b_{jk}(\zeta))$ would have been $(a_{jk}(\zeta'))$ except for the fact that the elements $b_{j,j-1}(\zeta)$ just below the main diagonal are not real positive but carry phases. But this can be easily taken care of by extracting a suitably chosen diagonal matrix on the right:

$$(b_{jk}(\zeta)) = (a_{jk}(\zeta')) D_n(\theta_2, \theta_3, \ldots, \theta_n, 0).$$

The point is that, according to the statement accompanying eqns.(4.12), after removal of this diagonal factor what remains is necessarily $A_n(\zeta) = (a_{jk}(\zeta'))$. Combining the above steps we get:

$$A'_n = A_n(\zeta') A_{n-1}'$$
$$= (b_{jk}(\zeta) A_{n-1}) D_n(\theta_1', \theta_2', \ldots, \theta'_{n-1})$$
$$= A_n(\zeta') D_n(\theta_2, \theta_3, \ldots, \theta_n, 0) A_{n-1} D_n(\theta_1', \theta_2', \ldots, \theta'_{n-1}),$$

so the changes induced in $\zeta$ and in $A_{n-1}$ by the gauge transformation (5.2) are:

$$\zeta'_j = e^{i(\theta_j + \theta'_j)} \eta_j, \quad j = 1, 2, \ldots, n;$$

$$A'_{n-1} = D_n(\theta_2, \theta_3, \ldots, \theta_n) A_{n-1} D_n(\theta_1', \theta_2', \ldots, \theta'_{n-1}).$$

We see from the structure of this result that we can tackle our problem recursively: The gauge transformation (5.2) at the $U(n)$ level translates into the change $\zeta \rightarrow \zeta'$ given by eqn.(5.9a) and a gauge transformation $A_{n-1} \rightarrow A'_{n-1}$ at the $U(n-1)$ level given by eqn.(5.9b). Therefore all gauge-invariant expressions that exist at the $A_{n-1}$ or $U(n-1)$ level survive when we move from $U(n-1)$ to $U(n)$, and in addition as the vector $\zeta \in B_n$ becomes available, new invariant phases involving $\zeta$ can be constructed. The number of the latter can be immediately computed: it is the difference between $\frac{1}{2}(n-1)(n-2)$ and $\frac{1}{2}(n-2)(n-3)$, namely the difference between the numbers of gauge-invariant phases at the $U(n)$ and the $U(n-1)$ levels, and this is $(n-2)$. Therefore the number of new independent phase invariants involving $A_n(\zeta)$, i.e., $\zeta'$ in an essential way must be $(n-2)$. These can now be isolated or explicitly constructed as follows.

From eqn.(5.9) we notice that $\theta_1$ and $\theta'_n$ appears only in the transformation law for $\zeta$, not for $A_{n-1}$. Therefore we first form the $(n-1)$ independent combinations $\zeta'_j \zeta_{j+1}$ to eliminate $\theta'_n$ completely:

$$\zeta'_j \zeta_{j+1} \rightarrow e^{-i(\theta_j - \theta_{j+1})} \zeta'_j \zeta_{j+1}, \quad j = 1, 2, \ldots, n - 1.$$  

(5.10)

Here $\theta_1$ occurs only in the transformation law for $\zeta'_1 \zeta_2$, being absent as we just mentioned in the law for $A_{n-1}$. Next we notice that the phases $\theta_1', \theta_2', \ldots, \theta_{n-1}'$, involved in $A'_{n-1}$, are completely absent in the transformation law (5.10) of $\zeta'_j \zeta_{j+1}$. Let us therefore look at the $(n-1)^{th}$ column, say, of $A_{n-1}$, which as is evident from eqn.(5.1) is just the $(n-1)$ component complex unit vector $\eta \in B_{n-1}$:

$$\begin{pmatrix} \ldots \ldots \eta_1 \ 0 \\ \ldots \ldots \eta_2 \ 0 \\ \ldots \ldots \eta_{n-1} \ 0 \\ 0 \ldots 0 \ 1 \end{pmatrix}.$$  

(5.11)

The “earlier” columns of $A_{n-1}$ are more complicated, as is clear from the structure of $A_{n-1}$ in eqn.(5.1). From eqn.(5.9b) we can read off the transformation law for the $\eta$’s under the gauge transformation (5.2):

$$\eta'_j = e^{i(\theta_{j+1} + \theta'_{j+1})} \eta_j, \quad j = 1, 2, \ldots, n - 1.$$  

(5.12)
To eliminate $\theta'_n$ we form the $(n-2)$ combinations $\eta_j \eta_{j+1}^*$ which transform thus:

$$\eta_j \eta_{j+1}^* \rightarrow e^{-i(\theta_j+\theta_{j+1})} \eta_j \eta_{j+1}^*, \ j = 1, 2, \ldots, n-2.$$  \hfill (5.13)

Comparing eqns.(5.10) and (5.13) we immediately obtain the expected $(n-2)$ independent (phase-type) invariants involving $\subseteq B_n$ in an essential manner, namely they can be taken to be the complex quantities

$$\eta_j \eta_{j+1}^* \zeta_{j+1+1} \zeta_{j+2}, \ j = 1, 2, \ldots, n-2.$$  \hfill (5.14)

By recursion the complete set of $\frac{1}{2}(n-1)(n-2)$ independent phase type invariants that can be formed from a generic matrix $A_n \in U(n)$ can be written down in terms of the canonical parametrisation (4.5) for $A_n$, and the list reads:

$$\alpha_j \alpha_{j+1}^2 \beta_{j+1}^2 \beta_{j+2}, \ j = 1;$$

$$\beta_j \beta_{j+1}^2 \gamma_{j+1}^2 \gamma_{j+2}, \ j = 1, 2;$$

$$\ldots \ldots$$

$$\xi_j \xi_{j+1}^2 \eta_{j+1}^2 \eta_{j+2}, \ j = 1, 2, \ldots, n-3;$$

$$\eta_j \eta_{j+1}^2 \zeta_{j+1+1}^2 \zeta_{j+2}, \ j = 1, 2, \ldots, n-2.$$  \hfill (5.15)

While we have here an explicit solution to our problem, the difficulty is that these invariants are not directly expressed in terms of the matrix elements of $A_n = (a_{jk}) \in U(n)$. It is true that in our parametrisation $\zeta_k$ is the last, $n^{th}$, column of $A_n$; but the previous, $(n-1)^{th}$, column involves both $\eta$ and $\xi$; the $(n-2)^{th}$ column involves $\xi, \eta$ and $\zeta$, and so on. The task that remains is to see how to translate the expressions (5.15), as far as their phases are concerned, into an algebraically equivalent set of $\frac{1}{2}(n-1)(n-2)$ expressions formed as simply as possible out of the matrix elements of $A_n$. We turn to this now, bringing in the 4-vertex Bargmann invariants of $A_n$.

As indicated in eqn.(4.3), a general 4-vertex Bargmann invariant requires the choice of some two rows, say $j$ and $\ell$ with $j < \ell$, and some two columns, say $k$ and $m$ with $k < m$, and use of the four matrix elements at their intersections:

$$\Delta_{j\ell km} \equiv \det a_{jk} a_{\ell k} a_{\ell m} a_{jm}^*.$$  \hfill (5.16)

But as far as phases go, we can see in a step by step manner that a general $\Delta_{j\ell km}$ reduces to a product of factors of the simpler form

$$\Delta_{jk} \equiv \Delta_{j,j+1,k,k+1}$$  \hfill (5.17)

involving some two adjacent rows and some two adjacent columns. This is to be understood modulo real positive definite factors coming from the squared moduli of some of the matrix elements of $A_n$. The two “recursion formulae” that help us achieve this simplification are:

$$\Delta_{j\ell km} = \Delta_{j\ell km-1} \Delta_{j\ell m-1} / |a_{j,m-1} a_{\ell,m-1}|^2;$$

$$= \Delta_{j\ell-1 km} \Delta_{j\ell km} / |a_{j-1,m} a_{\ell,m}|^2.$$  \hfill (5.18)

It therefore suffices to work with the $(n-1)^2$ expressions

$$\Delta_{jk} = a_{jk} a_{j+1,k} a_{j+1,k+1} a_{j,k+1}^*, \ j, k = 1, 2, \ldots, n-1,$$  \hfill (5.19)

and their phases. Our goal now is to (at least in principle and in the generic situation) express (the phases of) the $\frac{1}{2}(n-1)(n-2)$ complex invariants (5.15) in terms of (the phases of) the $(n-1)^2$ complex invariants (5.19). (In this process any number of real positive factors may intervene). We already have here an indication that the $(n-1)^2$ expressions (5.19) (more exactly their phases) cannot all be independent, the number of independent ones being only $\frac{1}{2}(n-1)(n-2)$. It will turn out, as we indicate below, that these may be taken to be the $\Delta_{jk}$ for $j < k \leq n-1$. Again the proof is recursive in nature.

Consider the $(n-1)$ invariants (5.14) that get added to all previous ones when we make the transition $U(n-1) \rightarrow U(n)$ and bring in the vector $\zeta \in B_n$. Instead of being expressed in terms of $\zeta$ and $\eta \in B_{n-1}$, we now show that they can be equally well expressed in terms of $\zeta$ and the penultimate, ie $(n-1)^{th}$, column of the complete $U(n)$ matrix $A_n$. Let us denote this column vector by $\eta_n \in B_n$; it is orthogonal to $\zeta$. As noted earlier, it is easily determined in terms of $\zeta$ and $\eta$ or, more conveniently for our purpose, $\eta$ is expressible in terms of $\zeta$ and $\eta$. Starting with
and transposing $A_n(\zeta)$ we get

$$A_{n-1}(\eta)A_{n-2} = A_n(\zeta)^\dagger A_n.$$  

(5.21)

Since the factor $A_{n-2}$ does not affect the last two columns on both sides, we can use the matrix elements (4.12,13) of $A_n(\zeta)$ to obtain:

$$\eta_j = \sum_{k=1,2,\ldots}^{j+1} a_{kj}(\zeta^\ast) w_k$$

to get expressions for $\xi_j$ in terms of $\eta$, $\rho$, and $\zeta$ defined in terms of $\zeta$ in eqn.(4.13). The result of comparing the $(n-2)^{th}$ columns of both sides of eqn.(5.27) is:
\[ \xi_j = \frac{\sigma_j p_{j+1}}{\sigma_{j+1} p_{j+2}} v_{j+2} - \frac{\sigma_j}{\sigma_{j+1} p_{j+1} p_{j+2}} \zeta_{j+2} \sum_{\ell=1}^{j+1} \xi_{\ell}^* v_{\ell} - \frac{\eta_j + 1}{\sigma_j \sigma_{j+1}} \sum_{k=1}^{j} \frac{\rho_k}{\rho_{k+1}} \eta_k^* v_{k+1} + \frac{\eta_j}{\sigma_j \sigma_{j+1}} \sum_{k=1}^{j} \frac{\eta_k \xi_{k}}{\rho_k \rho_{k+1}} \sum_{\ell=1}^{k} \xi_{\ell}^* v_{\ell}, \quad j = 1, 2, \ldots, n - 2. \] (5.28)

Here next we can use eqn.(5.22) to go from \( \eta \) to \( w \). Then we form the expressions \( \eta_j \xi_{j+1}^* \) and step by step work our way up to the invariants \( \xi_j \eta_{j+1}^* + \xi_{j+1}^* \eta_j \). We can then see that apart from various real factors we encounter \( \Delta_1 \)'s involving \( v \)'s and \( w \)'s, \( v \)'s and \( \zeta \)'s and \( \zeta \)'s. Using the reduction rules (5.18) the \( v - \zeta \) combinations can be eliminated in favour of the other two types. It is now clear that apart from the \( \Delta_{j,n-1} \) in eqn.(5.25) which appeared at the previous stage, the new quantities that come in now are \( \Delta_{j,n-2} \). But we know in advance that at this stage only \( (n-3) \) new independent invariants are available. As all the rows of \( \Delta_n \) are on equal footing, we conclude that the new \( \Delta_1 \)'s to be added now to the previous \( \Delta_{j,n-1} \) may be taken to be

\[ \Delta_{j,n-2} = v_j w_j^* v_{j+1}^* w_{j+1}, \quad j = 1, 2, \ldots, (n-3). \] (5.29)

In this manner one sees recursively that the \( \frac{1}{2}(n-1)(n-2) \) independent gauge-invariant phases in a general matrix \( A_n \in U(n) \) are the Bargmann invariants \( \Delta_{j,k} \) for \( j < k \leq n - 1 \). In any case such a choice is permitted. However the actual algebraic expression of a general \( \Delta_{j,k} \) in terms of this special subset may be rather involved, so one may freely use all \( \Delta_{j,k} \) in constructing interesting gauge-invariant expressions with various properties.

The upshot of these considerations is that the naturally available gauge-invariant phases for the continuous unitary evolution of an \( n \)-level quantum system, barring degeneracies and level-crossings, are \( n \) geometric phases \( \varphi_g[C_j] \) as defined in eqn.(3.4), and the \( (n-1)^2 \) primitive 4-vertex Bargmann invariants \( \Delta_{j,k} \) of eqn.(5.19); of the latter, only the \( \frac{1}{2}(n-1)(n-2) \) \( \Delta_{j,k} \)'s for \( j < k \leq n - 1 \) are independent. Any composite expression formed out of these ingredients is of course also invariant.

VI. OFF-DIAGONAL GEOMETRIC PHASES

It is evident from the definitions (2.6) that while the dynamical phase \( \varphi_{\text{dyn}}[C] \) is always numerically well-defined once the parametrised curve \( C \) is given, the total phase \( \varphi_{\text{tot}}[C] \) is only defined modulo \( 2\pi \), and moreover is undefined if the vectors \( \psi(s_1) \) and \( \psi(s_2) \) at the end points of \( C \) are orthogonal. These properties naturally carry over to the geometric phase \( \varphi_g[C] \): only defined modulo \( 2\pi \), undefined when \( \varphi_{\text{tot}}[C] \) is undefined. The Bargmann invariants (2.7) too share these problems of definition as far as their phases are concerned, which explains the limitation to generic situations.

Recently a very interesting attempt to define so-called off-diagonal geometric phases has been made to cover just these exceptional or problematic situations [11]. Specifically the idea is to set up gauge-invariant phases associated with the unitary evolution of an \( n \)-level quantum system, which remain well-defined even when one of the eigenvectors of the Hamiltonian at a final time \( t_2 \), say the \( k \)th one, happens to coincide with the \( j \)th eigenvector at the initial time \( t_1 \), with \( j \neq k \). In this situation, as \( \psi_j(t_1) \) and \( \psi_k(t_2) \) are the same up to a phase, both the geometric phases \( \varphi_g[C_j] \) and \( \varphi_g[C_k] \) become undefined since the inner products \( \langle \psi_j(t_1), \psi_j(t_2) \rangle \) and \( \langle \psi_k(t_1), \psi_k(t_2) \rangle \) vanish. We shall now briefly recall the basic quantities introduced in this new approach, and then show that the usual geometric phases and Bargmann invariants as defined earlier can completely handle the new situation. It is just that they must be put together in such combinations so that the potentially undefined factors in each precisely cancel one another in exceptional situations.

The notation for the evolution of an \( n \) level quantum system is as given in Section 3. The quantities defined in the off-diagonal geometric phases method, when expressed in our notations, are:

\[ I_j = \exp \left\{ -i \varphi_{\text{dyn}}[C_j] \right\}, \quad j = 1, 2, \ldots, n; \] (6.1a)
\[ \sigma_{jk} = \exp \left\{ i \arg(\psi_j, \phi_k) - i \varphi_{\text{dyn}}[C_k] \right\}, \quad j \neq k; \] (6.1b)
\[ \gamma_{jk} = \sigma_{jk} \sigma_{kj}, \quad j \neq k; \] (6.1c)
\[ \gamma_j = \exp \{ i \varphi_g[C_j] \}, \quad j = 1, 2, \ldots, n. \] (6.1d)

Of these, \( I_j \) and \( \sigma_{jk} \) are not gauge-invariant, but \( \gamma_{jk} \) and \( \gamma_j \) are gauge-invariant. In case for some \( j \neq k \) we have \( \{\psi_j, \phi_k\} = 1 \), it is clear that both \( \varphi_g[C_j] \) and \( \varphi_g[C_k] \) become undefined, but the "off-diagonal" quantity \( \gamma_{jk} \) remains well-defined.
The two-state or two-index quantity $\gamma_{jk}$ has been generalised to a multi-index quantity of order $\ell$ as follows:

$$
\gamma_{j_1j_2...j_\ell} = \sigma_{j_1j_2} \sigma_{j_2j_3} \ldots \sigma_{j_{\ell-1}j_\ell} \sigma_{j_\ell j_1},
$$

and this again is gauge-invariant.

We can now see that all these newly introduced gauge-invariant off-diagonal quantities $\gamma_{jk}, \gamma_{j_1j_2...j_\ell}$ are actually expressible completely in terms of the geometric phases and Bargmann invariants for the $n$-level system, in carefully chosen combinations:

$$
\gamma_{jk} = \exp \left\{ i \arg \Delta_4(\psi_j, \phi_k, \psi_k, \phi_j) + i \varphi_g[C_j] + i \varphi_g[C_k] \right\},
$$

$$
\gamma_{j_1j_2...j_\ell} = \exp \left\{ i \arg \Delta_{2\ell}(\phi_{j_1}, \psi_{j_1}, \phi_{j_2}, \psi_{j_2}, \ldots, \phi_{j_\ell}, \psi_{j_\ell}) + i \varphi_g[C_{j_1}] + i \varphi_g[C_{j_2}] + \ldots + i \varphi_g[C_{j_\ell}] \right\}.
$$

In the case of $\gamma_{jk},$ for example, we see that when $|(\psi_j, \phi_k)| = 1$ and $\varphi_g[C_j], \varphi_g[C_k]$ become undefined because the total phases $\varphi_{\text{tot}}[C_j]$ and $\varphi_{\text{tot}}[C_k]$ are undefined, there are compensating factors from $\Delta_4(\psi_j, \phi_k, \psi_k, \phi_j)$ that precisely cancel these parts of the individual geometric phases, so that $\gamma_{jk}$ remains unambiguous. The mechanism is similar in the case of the higher order expressions $\gamma_{j_1j_2...j_\ell}$

It has been shown that $\gamma_{j_1j_2...j_\ell}$ for $\ell \geq 4$ can be reduced to the expressions with $\ell = 2$ and $\ell = 3$, so these are the primitive ones. Among these, we can limit ourselves to choices obeying $j_1 < j_2$ when $\ell = 2$ and $j_1 = 1 < j_2 < j_3$ when $\ell = 3$, in counting independent quantities. However the upshot of our analysis is that we can always work with just the geometric phases $\varphi_g[C_j]$ and the independent $\Delta_4$'s listed in the previous Section (but for convenience employ all the $\Delta_{jk}$ if necessary). All gauge-invariant quantities can be built up out of them, so that conceptually the off-diagonal geometric phases are constructed out of previously known familiar building blocks.

VII. CONCLUDING REMARKS

We have carried out a complete analysis of the gauge-invariant objects for $n$-level quantum systems. This entails introduction of Bargmann invariants defined over two sets of orthonormal basis vectors, demonstration that the primitive Bargmann invariants are 4-vertex Bargmann invariants, and finally the identification of an algebraically independent set of 4-vertex Bargmann invariants which turn out to be $(n - 1)(n - 2)/2$ in number. In the process of achieving this task we developed a canonical form for $U(n)$ matrices in terms of a sequence of complex unit vectors of dimensions $n, n - 1, \ldots, 1$ which may be useful in other contexts as well. Indeed, this form has already found application in parametrising the CKM matrices which arise in the context of CP-violation in particle physics. The gauge-invariant building blocks constructed here are shown to provide a complete quantum kinematic picture of the recently discovered off-diagonal phases. The usefulness of the off-diagonal phases is thus extended far beyond the restrictive framework of adiabatic evolution. This reinforces the view that the Bargmann invariants and the traditional geometric phases, and suitably constructed combinations of them, suffice in answering all interesting questions in this domain.
