Global convergence of a hybrid trust-region
SQP-Filter algorithm for general nonlinear
programming

Nicholas I. M. Gould$^{1,2}$ and Philippe L. Toint$^{3,4}$

ABSTRACT
Global convergence to first-order critical points is proved for a variant of the trust-region SQP-filter algorithm analyzed in Fletcher, Gould, Leyffer and Toint (1999). This variant allows the use of two types of step strategies: the first decomposes the step into its normal and tangential components, while the second replaces this decomposition by a stronger condition on the associated model decrease.

1 Introduction

We analyze an algorithm for solving optimization problems where a smooth objective function is to be minimized subject to smooth nonlinear constraints. No convexity assumption is made. More formally, we consider the problem

$$\begin{align*}
\text{minimize} & \quad f(x) \\
\text{subject to} & \quad c_E(x) = 0 \\
& \quad c_I(x) \geq 0,
\end{align*}$$

where $f$ is a twice continuously differentiable real valued function of the variables $x \in \mathbb{R}^n$ and $c_E(x)$ and $c_I(x)$ are twice continuously differentiable functions from $\mathbb{R}^n$ into $\mathbb{R}^m$ and from $\mathbb{R}^n$ into $\mathbb{R}^p$, respectively. Let $c(x)^T = (c_E(x)^T \ c_I(x)^T)$.

The class of algorithms that we discuss belongs to the class of trust-region methods and, more specifically, to that of filter methods introduced by Fletcher and Leyffer (1997), in which the use of a penalty function, a common feature of the large majority of the algorithms for constrained optimization, is replaced by the introduction of a so-called “filter”.

A global convergence theory for an algorithm of this class is proposed in Fletcher, Leyffer and Toint (1998), in which the objective function is locally approximated by a linear function, leading, at each iteration, to the (exact) solution of a linear program. This algorithm therefore mixes the use of the filter with sequential linear programming (SLP). Similar results are shown in Fletcher, Leyffer and Toint (2000), where the approximation of the objective function is quadratic, leading to sequential quadratic programming (SQP) methods, but at the price of finding a global minimizer of the possibly nonconvex quadratic programming subproblem, which is known to be a very difficult task. Convergence of SQP filter methods was also considered in Fletcher et al. (1999), where the SQP step was decomposed in “normal” and “tangential” components. Although this latter procedure is computationally well-defined and considerably less complex than finding the global minimum of a general quadratic program, it may sometimes be costly, and a simpler strategy, where the step is computed “as a whole” can also be of practical interest whenever possible. The purpose of this paper, a companion of Fletcher et al. (1999), is to analyze a hybrid algorithm that uses the decomposition of the step into normal and tangential components as infrequently as possible.

2 A Hybrid Trust-Region SQP-Filter Algorithms

For the sake of completeness and clarity, we review briefly the main constituent parts of the SQP algorithm discussed in Fletcher et al. (1999). Sequential quadratic programming methods are iterative. At a given iterate $x_k$, they implicitly apply Newton’s method to solve (a local version of) the first-order necessary optimality conditions by solving the quadratic programming subproblem $\text{QP}(x_k)$ given by

$$\begin{align*}
\text{minimize} & \quad f_k + \langle g_k, s \rangle + \frac{1}{2} \langle s, H_k s \rangle \\
\text{subject to} & \quad c_E(x_k) + A_E(x_k) s = 0 \\
& \quad c_I(x_k) + A_I(x_k) s \geq 0,
\end{align*}$$

where $f_k = f(x_k)$, $g_k = g(x_k) \overset{\text{def}}{=} \nabla_x f(x_k)$, where $A_E(x_k)$ and $A_I(x_k)$ are the Jacobians of the constraint functions $c_E$ and $c_I$ at $x_k$ and where $H_k$ is a symmetric matrix. We will not immediately
be concerned about how $H_k$ is obtained, but we will return to this point in Section 3. Assuming a suitable value of $H_k$ can be found, the solution of $\text{QP}(x_k)$ then yields a step $s_k$. If $s_k = 0$, then $x_k$ is first-order critical for problem (1.1).

2.1 The filter

Unfortunately, due to the locally convergent nature of Newton’s iteration, the step $s_k$ may not always be very good. Thus, having computed (in a so far unspecified manner) a step $s_k$ from our current iterate $x_k$, we need to decide whether the trial point $x_k + s_k$ is any better than $x_k$ as an approximate solution to our original problem (1.1). This is achieved by using the notion of a filter, itself based on that of dominance.

If we define the feasibility measure

$$
\theta(x) = \max \left[ 0, \max_{i \in E} |c_i(x)|, \max_{i \in T} -c_i(x) \right],
$$

(2.2)

we say that a point $x_1$ dominates a point $x_2$ whenever

$$
\theta(x_1) \leq \theta(x_2) \quad \text{and} \quad f(x_1) \leq f(x_2).
$$

Thus, if iterate $x_k$ dominates iterate $x_j$, the latter is of no real interest to us since $x_k$ is at least as good as $x_j$ on account of both feasibility and optimality. All we need to do now is to remember iterates that are not dominated by any other iterates using a structure called a filter. A filter is a list $\mathcal{F}$ of pairs of the form $(\theta, f)$ such that either

$$
\theta_i < \theta_j \quad \text{or} \quad f_i < f_j
$$

for $i \neq j$. Fletcher et al. (1999) propose to accept a new trial iterate $x_k + s_k$ only if it is not dominated by any other iterate in the filter and $x_k$. In the vocabulary of multi-criteria optimization, this amounts to building elements of the efficient frontier associated with the bi-criteria problem of reducing infeasibility and the objective function value. We may describe this concept by associating with each iterate $x_k$ its $(\theta, f)$-pair $(\theta_k, f_k)$ and accept $x_k + s_k$ only if its $(\theta, f)$-pair does not lie in the two-dimensional space spanned by constraint violation and objective function value, above and on the right of a previously accepted pair (including that associated with $x_k$).

While the idea of not accepting dominated trial points is simple and elegant, it needs to be refined a little in order to provide an efficient algorithmic tool. In particular, we do not wish to accept $x_k + s_k$ if its $(\theta, f)$-pair is arbitrarily close to that of $x_k$ or that of a point already in the filter. Thus Fletcher et al. (1999) set a small “margin” around the border of the dominated part of the $(\theta, f)$-space in which we shall also reject trial points. Formally, we say that a point $x$ is acceptable for the filter if and only if

$$
\theta(x) < (1 - \gamma \theta) \theta_j \quad \text{or} \quad f(x) < f_j - \gamma \theta \theta_j \quad \text{for all} \quad (\theta_j, f_j) \in \mathcal{F},
$$

(2.3)

for some $\gamma \in (0, 1)$. We also say that $x$ is “acceptable for the filter and $x_k$” if (2.3) holds with $\mathcal{F}$ replaced by $\mathcal{F} \cup (\theta_k, f_k)$. We thus consider moving from $x_k$ to $x_k + s_k$ only if $x_k + s_k$ is acceptable for the filter and $x_k$.

As the algorithm progresses, Fletcher et al. (1999) add $(\theta, f)$-pairs to the filter. If an iterate $x_k$ is acceptable for $\mathcal{F}$, this is done by adding the pair $(\theta_k, f_k)$ to the filter and by removing from
it every other pair \((\theta_j, f_j)\) such that \(\theta_j \geq \theta_k\) and \(f_j - \gamma_\theta \theta_j \geq f_k - \gamma_\theta \theta_k\). We also refer to this operation as “adding \(x_k\) to the filter” although, strictly speaking, it is the \((\theta, f)\)-pair which is added.

We conclude this introduction to the notion of a filter by noting that, if a point \(x_k\) is in the filter or is acceptable for the filter, then any other point \(x\) such that

\[
\theta(x) \leq (1 - \gamma_\theta) \theta_k \quad \text{and} \quad f(x) \leq f_k - \gamma_\theta \theta_k
\]

is also be acceptable for the filter and \(x_k\).

### 2.2 The composite SQP step

Of course, the step \(s_k\) must be computed, typically by solving, possibly approximately, a variant of (2.1). In the trust-region approach, one takes into account the fact that (2.1) only approximates our original problem locally: the step \(s_k\) is thus restricted in norm to ensure that \(x_k + s_k\) remains in a trust-region centred at \(x_k\), where we believe this approximation to be adequate. In other words, we replace \(\text{QP}(x_k)\) by the subproblem \(\text{TRQP}(x_k, \Delta_k)\) given by

\[
\begin{align*}
\text{minimize} & \quad m_k(x_k + s) \\
\text{subject to} & \quad c_E(x_k) + A_E(x_k)s = 0, \\
& \quad c_I(x_k) + A_I(x_k)s \geq 0, \\
& \quad \|s\| \leq \Delta_k,
\end{align*}
\]

for some (positive) value of the trust-region radius \(\Delta_k\), where we have defined

\[
m_k(x_k + s) = f_k + \langle g_k, s \rangle + \frac{1}{2}(s, H_k s),
\]

and where \(\| \cdot \|\) denotes the Euclidean norm. This latter choice is purely for ease of exposition. We could equally use a family of iteration dependent norms \(\| \cdot \|_k\), so long as we require that all members of the family are uniformly equivalent to the Euclidean norm. The interested reader may verify that all subsequent developments can be adapted to this more general case by introducing the constants implied by this uniform equivalence wherever needed.

Remarkably, most of the existing SQP algorithms assume that an exact local solution of \(\text{QP}(x_k)\) or \(\text{TRQP}(x_k, \Delta_k)\) is found, although attempts have been made by Dembo and Tulowitzki (1983) and Murray and Prieto (1995) to design conditions under which an approximate solution of the subproblem is acceptable. In contrast, the algorithm of Fletcher et al. (1999) is in spirit to the composite-step SQP methods pioneered by Vardi (1985), Byrd, Schnabel and Shultz (1987), and Omojokun (1989) and later developed by several authors, including Biegler, Nocedal and Schmid (1995), El-Alem (1995, 1999), Byrd, Gilbert and Nocedal (2000a), Byrd, Hribar and Nocedal (2000b), Bielschowsky and Gomes (1998), Liu and Yuan (1998) and Lalee, Nocedal and Plantenga (1998). It decomposes the step \(s_k\) into the sum of two distinct components, a normal step \(n_k\), such that \(x_k + n_k\) satisfies the constraints of \(\text{TRQP}(x_k, \Delta_k)\), and a tangential step \(t_k\), whose purpose is to obtain reduction of the objective function’s model while continuing to satisfy those constraints. The step \(s_k\) is then called composite. More formally, we write

\[
s_k = n_k + t_k
\]

and assume that

\[
c_E(x_k) + A_E(x_k)n_k = 0, \quad c_I(x_k) + A_I(x_k)n_k \geq 0,
\]
\|s_k\| \leq \Delta_k, \quad (2.8)

and

\[ c_\mathcal{E}(x_k) + A_\mathcal{E}(x_k)s_k = 0, \quad c_\mathcal{I}(x_k) + A_\mathcal{I}(x_k)s_k \geq 0. \quad (2.9) \]

Of course, this is a strong assumption, since in particular (2.7) or (2.8)/(2.9) may not have a solution. We shall return to this possibility shortly. Given our assumption, there are many ways to compute \( n_k \) and \( t_k \). For instance, we could compute \( n_k \) from

\[ n_k = P_k[x_k] - x_k, \quad (2.10) \]

where \( P_k \) is the orthogonal projector onto the feasible set of QP\((x_k)\). No specific choice for \( n_k \)

is made, but one instead assumes that \( n_k \) exists when the maximum violation of the nonlinear constraints at the \( k \)-th iterate \( \theta_k \overset{\text{def}}{=} \theta(x_k) \) is sufficiently small, and that \( n_k \) is then reasonably scaled with respect to the values of the constraints. In other words, Fletcher et al. (1999) assume that

\[ n_k \text{ exists and } \|n_k\| \leq \kappa_{\text{usc}}\theta_k, \quad \text{whenever } \theta_k \leq \delta_n, \quad (2.11) \]

for some constants \( \kappa_{\text{usc}} > 0 \) and \( \delta_n > 0 \). This assumption is also used by Dennis, El-Alem and Maciel (1997) and Dennis and Vicente (1997) in the context of problems with equality constraints only. It can be shown not to impose conditions on the constraints or the normal step itself that are unduly restrictive (see Fletcher et al. (1999) for a discussion).

Having defined the normal step, we are in position to use it if it falls within the trust-region, that is if \( \|n_k\| \leq \Delta_k \). In this case, we write

\[ x^N_k = x_k + n_k, \quad (2.12) \]

and observe that \( n_k \) satisfies the constraints of TRQP\((x_k, \Delta_k)\) and thus also of QP\((x_k)\). It is crucial to note, at this stage, that such an \( n_k \) may fail to exist because the constraints of QP\((x_k)\)

may be incompatible, in which case \( P_k \) is undefined, or because all feasible points for QP\((x_k)\)

may lie outside the trust region.

Let us continue to consider the case where this problem does not arise, and a normal step \( n_k \) has been found with \( \|n_k\| \leq \Delta_k \). We then have to find a tangential step \( t_k \), starting from \( x^N_k \) and satisfying (2.8) and (2.9), with the aim of decreasing the value of the objective function. As always in trust-region methods, this is achieved by computing a step that produces a sufficient decrease in \( m_k \), which is to say that we wish \( m_k(x^N_k) - m_k(x_k + s_k) \) to be “sufficiently large”. Of course, this is only possible if the maximum size of \( t_k \) is not too small, which is to say that \( x^N_k \) is not too close to the trust-region boundary. We formalize this condition by replacing our condition that \( \|n_k\| \leq \Delta_k \) by the stronger requirement that

\[ \|n_k\| \leq \kappa_\Delta \Delta_k \min[1, \kappa_\mu \Delta_k^\mu_k], \quad (2.13) \]

for some \( \kappa_\Delta \in (0, 1) \), some \( \kappa_\mu > 0 \) and some \( \mu_k \in [0, 1) \). If condition (2.13) does not hold, Fletcher et al. (1999) presume that the computation of \( t_k \) is unlikely to produce a satisfactory decrease in \( m_k \), and proceed just as if the feasible set of TRQP\((x_k, \Delta_k)\) were empty. If \( n_k \) can be computed and (2.13) holds, TRQP\((x_k, \Delta_k)\) is said to be compatible for \( \mu \). In this case at least a sufficient model decrease seems possible, in the form of a familiar Cauchy-point condition. In
order to formalize this notion, we recall that the feasible set of \( \text{QP}(x_k) \) is convex, and we can therefore introduce the first-order criticality measure

\[
\chi_k = \min_{\|z(x_k)\| = 0, \quad c_z(x_k) + A_z(x_k)(n_k + t) \geq 0} \langle g_k + H_k n_k, t \rangle
\]  

(2.14)

(see Conn, Gould, Sartenaer and Toint, 1993). Note that this function is zero if and only if \( x_k^n \) is a first-order critical point of the linearized “tangential” problem

\[
\begin{align*}
\text{minimize} & \quad \langle g_k + H_k n_k, t \rangle + \frac{1}{2} \langle H_k t, t \rangle \\
\text{subject to} & \quad A_c(x_k) t = 0 \\
& \quad c_z(x_k) + A_z(x_k)(n_k + t) \geq 0,
\end{align*}
\]  

(2.15)

which is equivalent to \( \text{QP}(x_k) \) with \( s = n_k + t \). The sufficient decrease condition then consists in assuming that there exists a constant \( \kappa_{\text{red}} > 0 \) such that

\[
m_k(x_k^n) - m_k(x_k^n + t_k) \geq \kappa_{\text{red}} \chi_k \min \left[ \frac{\chi_k}{\beta_k}, \Delta_k \right],
\]  

(2.16)

whenever \( \text{TRQP}(x_k, \Delta_k) \) is compatible, where \( \beta_k = 1 + \|H_k\| \). We know from Toint (1988) and Conn et al. (1993) that this condition holds if the model reduction exceeds that which would be obtained at the generalized Cauchy point, that is the point resulting from a backtracking curvilinear search along the projected gradient path from \( x_k^n \), that is

\[
x_k(\alpha) = P_k[x_k^n - \alpha \nabla m_k(x_k^n)].
\]

This technique therefore provides an implementable algorithm for computing a step that satisfies (2.16) (see Gould, Hribar and Nocedal, 1998 for an example in the case where \( c(x) = c_c(x) \), or Toint, 1988 and Moré and Toraldo, 1991 for the case of bound constraints), but, of course, reduction of \( m_k \) beyond that imposed by (2.16) is often possible and desirable if fast convergence is sought. Also note that the minimization problem of the right-hand side of (2.14) reduces to a linear programming problem if we choose to use a polyhedral norm in its definition at iteration \( k \).

If \( \text{TRQP}(x_k, \Delta_k) \) is not compatible for \( \mu \), that is when the feasible set determined by the constraints of \( \text{QP}(x_k) \) is empty, or the freedom left to reduce \( m_k \) within the trust region is too small in the sense that (2.13) fails, solving \( \text{TRQP}(x_k, \Delta_k) \) is most likely pointless, and we must consider an alternative. Observe that, if \( \theta(x_k) \) is sufficiently small and the true nonlinear constraints are locally compatible, the linearized constraints should also be compatible, since they approximate the nonlinear constraints (locally) correctly. Furthermore, the feasible region for the linearized constraints should then be close enough to \( x_k \) for there to be some room to reduce \( m_k \), at least if \( \Delta_k \) is large enough. If the nonlinear constraints are locally incompatible, we have to find a neighbourhood where this is not the case, since the problem (1.1) does not make sense in the current one. Fletcher et al. (1999) thus rely on a restoration procedure, whose aim is to produce a new point \( x_k + r_k \) for which \( \text{TRQP}(x_k + r_k, \Delta_{k+1}) \) is compatible for some \( \Delta_{k+1} > 0 \)—another condition will actually be needed, which we will discuss shortly.

The idea of the restoration procedure is to (approximately) solve

\[
\min_{x \in \mathbb{R}^n} \theta(x)
\]  

(2.17)
starting from $x_k$, the current iterate. This is a non-smooth problem, but there exist methods, possibly of trust-region type (such as that suggested by Yuan, 1994), which can be successfully applied to solve it. Thus we will not describe the restoration procedure in detail. Note that we have chosen here to reduce the infinity norm of the constraint violation, but we could equally well consider other norms, such as $\ell_1$ or $\ell_2$, in which case the methods of Fletcher and Leyffer (1998) or El-Halabi and Tapia (1995) and Dennis, El-Alem and Williamson (1999) can respectively be considered. Of course, this technique only guarantees convergence to a first-order critical point of the chosen measure of constraint violation, which means that, in fact, the restoration procedure may fail as this critical point may not be feasible for the constraints of (1.1). However, even in this case, the result of the procedure is of interest because it typically produces a local minimizer of $\theta(x)$, or of whatever other measure of constraint violation we choose for the restoration, yielding a point of locally-least infeasibility.

There seems to be no easy way to circumvent this drawback, as it is known that finding a feasible point or proving that no such point exists is a global optimization problem and can be as difficult as the optimization problem (1.1) itself. One therefore has to accept two possible outcomes of the restoration procedure: either the procedure fails in that it does not produce a sequence of iterates converging to feasibility, or a point $x_k + \tau_k$ is produced such that $\theta(x_k + \tau_k)$ is as small as desired.

2.3 An alternative step

Is it possible to find a cheaper alternative to computing a normal step, finding a generalized Cauchy point and explicitly checking (2.16)? Suppose, for now, that it is possible to compute a point $x_k + s_k$ directly to satisfy the constraints of TRQP($x_k, \Delta_k$) and for which

$$m_k(x_k) - m_k(x_k + s_k) \geq \kappa_{\text{inc}} \min[\pi_k, \Delta_k]$$

and $\pi_k = \pi(x_k)$, where $\pi$ is a continuous function of its argument that is a criticality measure for TRQP($x_k, \Delta_k$). Such a $s_k$ could for instance be computed by applying any efficient method to this latter problem (we might think of interior point methods of the type described in Conn, Gould, Orban and Toint, 2000) for instance, and its performance could be assessed by computing

$$\pi(x) = \min_{y \| y \| \geq 0} \| g(x) - A(x)^T y \|.$$  

Of course, nothing guarantees that such an $s_k$ exists (depending on our choice of $\pi(x)$) or is cheaply computable for each $x_k$, which means that we may have to resort to the normal-tangential strategy of Fletcher et al. (1999) if such problems arise. However, if we can find $s_k$ at a fraction of the cost of computing $n_k$ and $l_k$, can we use it inside an SQP-filter algorithm and maintain the desirable convergence to first-order critical points?

Obviously, the answer to that question depends on the manner in which the use of $s_k$ is integrated into a complete algorithm.

2.4 A hybrid SQP-filter Algorithm

We have now discussed the main ingredients of the class of algorithms we wish to consider, and we are now ready to define it formally as Algorithm 2.1, shown on the next page.
Algorithm 2.1: Hybrid SQP-filter Algorithm

Step 0: Initialization. Let an initial point $x_0$, an initial trust-region radius $\Delta_0 > 0$ and an initial symmetric matrix $H_0$ be given, as well as constants $\gamma_0 < \gamma_1 \leq 1 \leq \gamma_2$, $0 < \eta_1 \leq \eta_2 < 1$, $\gamma_\theta \in (0,1)$, $\kappa_\theta \in (0,1)$, $\kappa_\Delta \in (0,1]$, $\kappa_\mu > 0$, $\mu \in (0,1)$, $\psi > 1/(1 + \mu)$, $\kappa_u > 0$ and $\kappa_{\text{imd}} \in (0,1]$. Compute $f(x_0)$ and $c(x_0)$. Set $\mathcal{F} = \emptyset$ and $k = 0$.

Step 1: Test for optimality. If $\theta_k = 0$ and either $\chi_k = 0$ or $\pi_k = 0$, stop.

Step 2: Alternative step. If
\[
\theta_k > \kappa_u \Delta_k \min[1, \Delta_k^\psi], \tag{2.19}
\]
set $\mu_k = \mu$ and go to Step 3. Otherwise, attempt to compute a step $s_k$ that satisfies the constraints of TRQP($x_k, \Delta_k$) and (2.18). If this succeeds, go to Step 4. Otherwise, set $\mu_k = 0$.

Step 3: Composite step.

Step 3a: Normal component. Attempt to compute a normal step $n_k$. If TRQP($x_k, \Delta_k$) is compatible for $\mu_k$, go to Step 3b. Otherwise, include $x_k$ in the filter and compute a restoration step $r_k$ for which TRQP($x_k + r_k, \Delta_{k+1}$) is compatible for some $\Delta_{k+1} > 0$, and $x_k + r_k$ is acceptable for the filter. If this proves impossible, stop. Otherwise, define $x_{k+1} = x_k + r_k$ and go to Step 7.

Step 3b: Tangential component. Compute a tangential step $t_k$ and set $s_k = n_k + t_k$.

Step 4: Tests to accept the trial step.

- Evaluate $c(x_k + s_k)$ and $f(x_k + s_k)$.
- If $x_k + s_k$ is not acceptable for the filter and $x_k$, set $x_{k+1} = x_k$, choose $\Delta_{k+1} \in [\gamma_0 \Delta_k, \gamma_1 \Delta_k]$, set $n_{k+1} = n_k$ if Step 3 was executed, and go to Step 7.
- If
\[
m_k(x_k) - m_k(x_k + s_k) \geq \kappa_\theta \theta_k^\psi, \tag{2.20}
\]
and
\[
\rho_k \frac{f(x_k) - f(x_k + s_k)}{m_k(x_k) - m_k(x_k + s_k)} < \eta_1, \tag{2.21}
\]
again set $x_{k+1} = x_k$, choose $\Delta_{k+1} \in [\gamma_0 \Delta_k, \gamma_1 \Delta_k]$, set $n_{k+1} = n_k$ if Step 3 was executed, and go to Step 7.

Step 5: Test to include the current iterate in the filter. If (2.20) fails, include $x_k$ in the filter $\mathcal{F}$.

Step 6: Move to the new iterate. Set $x_{k+1} = x_k + s_k$ and choose $\Delta_{k+1}$ such that
\[
\Delta_{k+1} \in [\Delta_k, \gamma_2 \Delta_k] \text{ if } \rho_k \geq \eta_2 \text{ and (2.20) holds.}
\]

Step 7: Update the Hessian approximation. Determine $H_{k+1}$. Increment $k$ by one and go to Step 1.
This algorithm differs from that of Fletcher et al. (1999) in that it contains the alternative step strategy, but also because it allows the normal step to satisfy (2.13) with $\mu = 0$ whenever (2.19) holds, that is whenever the current iterate is sufficiently feasible. (As we will see later, (2.13) with $\mu > 0$ can be viewed as an implicit technique to impose (2.19).)

As in Fletcher and Leyffer (1997) and Fletcher and Leyffer (1998), one may choose $\psi = 2$ (Note that the choice $\psi = 1$ is always possible because $\mu > 0$). Reasonable values for the constants might then be

$$
\gamma_0 = 0.1, \quad \gamma_1 = 0.5, \quad \gamma_2 = 2, \quad \eta_1 = 0.01, \quad \eta_2 = 0.9,
\gamma_\theta = 10^{-4}, \quad \kappa_\Delta = 0.7, \quad \kappa_\mu = 100, \quad \mu = 0.01, \quad \kappa_\theta = 10^{-4}, \quad \text{and} \quad \kappa_{\text{mu}} = 0.01.
$$

but it is too early to know if these are even close to the best possible choices.

As in Fletcher et al. (1999), some comments on this algorithm are now in order. Observe first that, by construction, every iterate $x_k$ must be acceptable for the filter at the beginning of iteration $k$, irrespective of the possibility that it is added to the filter later. Also note that the restoration step $r_k$ cannot be zero, that is restoration cannot simply entail enlarging the trust-region radius to ensure (2.13), even if $n_k$ exists. This is because $x_k$ is added to the filter before $r_k$ is computed, and $x_k + r_k$ must be acceptable for the filter which now contains $x_k$. Also note that the restoration procedure cannot be applied on two successive iterations, since the iterate $x_k + r_k$ produced by the first of these iterations is both compatible and acceptable for the filter.

For the restoration procedure in Step 3a to succeed, we have to evaluate whether TRQP($x_k + r_k, \Delta k+1$) is compatible for a suitable value of $\Delta k+1$. This requires that a suitable normal step be computed which successfully passes the test (2.13). Of course, once this is achieved, this normal step may be reused at iteration $k + 1$, if the composite step strategy is used.

As it stands, the algorithm is not specific about how to choose $\Delta k+1$ during a restoration iteration. On one hand, there is an advantage to choosing a large $\Delta k+1$, since this allows a large step and one hopes good progress. It also makes it easier to satisfy (2.13). On the other, it may be unwise to choose it to be too large, as this may possibly result in a large number of unsuccessful iterations, during which the radius is reduced, before the algorithm can make any progress. A possible choice might be to restart from the radius obtained during the restoration iteration itself, if it uses a trust-region method. Reasonable alternatives would be to use the average radius observed during past successful iterations, or to apply the internal doubling strategy of Byrd et al. (1987) to increase the new radius, or even to consider the technique described by Sartenaer (1997). However, we recognize that extensive numerical experience will remain the ultimate measure of any suggestion at this level.

The role of condition (2.20) may be interpreted as follows. If this condition fails, then one may think that the constraint violation is significant and that one should aim to improve on this situation in the future, by inserting the current point in the filter. Fletcher and Leyffer (1997) use the term of “$\theta$-step” in such circumstances, to indicate that the main preoccupation is to improve feasibility . On the other hand, if condition (2.20) holds, then the reduction in the objective function predicted by the model is more significant than the current constraint violation and it is thus appealing to let the algorithm behave as if it were unconstrained. Fletcher and Leyffer (1997) use the term of “$\mu$-step” to denote the step generated, in order to reflect the dominant role of the objective function $f$ in this case. In this case, it is important that the predicted decrease in the model is realized by the actual decrease in the function, which is why
we also require that (2.21) does not hold. In particular, if the iterate $x_k$ is feasible, then (2.19) and (2.11) imply that $x_k = x_k^N$ and we obtain that

$$\kappa_0 \theta_k^N = 0 \leq m_k(x_k^N) - m_k(x_k + s_k) = m_k(x_k) - m_k(x_k + s_k).$$

(2.22)

As a consequence, the filter mechanism is irrelevant if all iterates are feasible, and the algorithm reduces to a classical unconstrained trust-region method. Another consequence of (2.22) is that no feasible iterate is ever included in the filter, which is crucial in allowing finite termination of the restoration procedure. Indeed, if the restoration procedure is required at iteration $k$ of the filter algorithm and produces a sequence of points $\{x_{k,j}\}$ converging to feasibility, there must be an iterate $x_{k,j}$ for which

$$\theta_{k,j} \equiv \theta(x_{k,j}) \leq \min \left[ (1 - \gamma_0) \theta_k^{\min} , \frac{\kappa_0 \Delta_{k+1}}{\kappa_{\text{acc}}} \min [1, \kappa_\mu \Delta_{k+1}^\mu] \right],$$

for any given $\Delta_{k+1} > 0$, where

$$\theta_k^{\min} = \min_{i \in \mathcal{Z}, i \leq k} \theta_i > 0$$

and

$$\mathcal{Z} = \{ k \mid x_k \text{ is added to the filter} \}.$$

Moreover, $\theta_{k,j}$ must eventually be small enough to ensure, using our assumption on the normal step, the existence of a normal step $n_{k,j}$ from $x_{k,j}$. In other words, the restoration iteration must eventually find an iterate $x_{k,j}$ which is acceptable for the filter and for which the normal step exists and satisfies (2.13), i.e. an iterate $x_j$ which is both acceptable and compatible. As a consequence, the restoration procedure will terminate in a finite number of steps, and the filter algorithm may then proceed. Note that the restoration step may not terminate in a finite number of iterations if we do not assume the existence of the normal step when the constraint violation is small enough, even if this violation converges to zero (see Fletcher, Leyffer and Toint, 1998, for an example).

Notice also that (2.20) ensures that the denominator of $\rho_k$ in (2.21) will be strictly positive whenever $\theta_k$ is. If $\theta_k = 0$, then $x_k = x_k^N$, and the denominator of (2.21) will be strictly positive unless $x_k$ is a first-order critical point because of (2.16).

The attentive reader will have observed that we have defined $n_{k+1}$ in Step 4 in the cases where iteration $k$ is unsuccessful (just before branching back to Step 2), while we may not use it if the alternative step of Step 2 is then used at iteration $k+1$. This is to keep the expression of the algorithm as general as possible: a more restrictive version would impose a branch back to Step 3b from Step 4 if iteration $k$ is unsuccessful, but this would then prevent the use of an alternative step at iteration $k+1$. We have chosen not to impose that restriction, but we obviously require that $n_{k+1}$ is used in Step 3a whenever it has been set at iteration $k$, instead of recomputing it from scratch.

Finally, note that Step 6 allows a relatively wide choice of the new trust-region radius $\Delta_{k+1}$. While the stated conditions are sufficient for the theory developed below, one must obviously be more specific in practice. For instance, one may wish to distinguish, at this point in the algorithm, the cases where (2.20) fails or holds. If (2.20) holds, the main effect of the current iteration is not to reduce the model (which makes the value of $\rho_k$ essentially irrelevant), but rather to reduce the constraint violation (which is taken care of by inserting the current iterate in the filter at Step 5).
In this case, Step 6 imposes no further restriction on $\Delta_{k+1}$. In practice, it may be reasonable not to reduce the trust-region radius, because this might cause too small steps towards feasibility or an unnecessary restoration phase. However, there is no compelling reason to increase the radius either, given the compatibility of TRQP($x_k, \Delta_k$). A reasonable strategy might then be to choose $\Delta_{k+1} = \Delta_k$. If, on the other hand, (2.20) holds, the emphasis of the iteration is then on reducing the objective function, a case akin to unconstrained minimization. Thus a more detailed rule of the type

$$\Delta_{k+1} \in \begin{cases} [\gamma_1 \Delta_k, \gamma_2 \Delta_k] & \text{if } \rho_k \in [\eta_1, \eta_2), \\ [\Delta_k, \gamma_2 \Delta_k] & \text{if } \rho_k \geq \eta_2. \end{cases}$$

seems reasonable in these circumstances.

3 Convergence to First-Order Critical Points

We now prove that our hybrid algorithm generates a globally convergent sequence of iterates, at least if the restoration iteration always succeeds. For the purpose of our analysis, we shall consider

$$S = \{ k \mid x_{k+1} = x_k + s_k \},$$

the set of (indices of) successful iterations,

$$\mathcal{R} = \left\{ k \mid \begin{array}{l} \text{Step 3 is executed and} \\
\text{either TRQP}(x_k, \Delta_k) \text{ has no feasible point} \\
\text{or } ||n_k|| > \kappa_\Delta \Delta_k \min[1, \kappa_\mu \Delta_k^\mu] \end{array} \right\},$$

the set of restoration iterations,

$$\mathcal{A} = \{ k \mid \text{the alternative step is used at iteration } k \},$$

and

$$\mathcal{C} = \{ k \mid s_k = n_k + t_k \},$$

the set of iterations where a composite step is used (with $\mu_k \geq 0$). Note that (2.19) implies that

$$\theta_k \leq \kappa_u \Delta_k \min[1, \Delta_k^\mu] \leq \kappa_u \Delta_k^{1+\mu},$$

(3.1)

for every $k \in \mathcal{A}$. Also note that $\{1, 2, \ldots\} = \mathcal{A} \cup \mathcal{C} \cup \mathcal{R}$ and that $\mathcal{R} \subseteq \mathcal{Z}$.

In order to obtain our global convergence result, we will use the assumptions

**AS1:** $f$ and the constraint functions $c_\mathcal{E}$ and $c_\mathcal{L}$ are twice continuously differentiable;

**AS2:** there exists $\kappa_{\text{unb}} > 1$ such that

$$\|H_k\| \leq \kappa_{\text{unb}} - 1 < \kappa_{\text{unb}} \text{ for all } k,$$

**AS3:** the iterates $\{x_k\}$ remain in a closed, bounded domain $X \subset \mathbb{R}^n$. 

10
If, for example, $H_k$ is chosen as the Hessian of the Lagrangian function

$$
\ell(x, y) = f(x) + \langle y_\xi, c_\xi(x) \rangle + \langle y_{\bar{I}}, c_{\bar{I}}(x) \rangle
$$
at $x_k$, in that

$$
H_k = \nabla_{xx} f(x_k) + \sum_{i \in \mathcal{E} \cup \mathcal{I}} [y_k]_i \nabla_{xx} c_i(x_k),
$$

(3.2)

where $[y_k]_i$ denotes the $i$-th component of the vector of Lagrange multipliers $y_k^T = (y_{\xi,k}^T, y_{\bar{I},k}^T)$, then we see from AS1 and AS3 that AS2 is satisfied when these multipliers remain bounded. The same is true if the Hessian matrices in (3.2) are replaced by bounded approximations.

A first immediate consequence of AS1–AS3 is that there exists a constant $\kappa_{\text{ubh}} > 1$ such that, for all $k,$

$$
|f(x_k + s_k) - m_k(x_k + s_k)| \leq \kappa_{\text{ubh}} \Delta_k^2.
$$

(3.3)

A proof of this property, based on Taylor expansion, may be found, for instance, in Toint (1988). A second important consequence of our assumptions is that AS1 and AS3 together directly ensure that, for all $k,$

$$
f^\min \leq f(x_k) \leq f^\max \quad \text{and} \quad 0 \leq \theta_k \leq \theta^\max
$$

(3.4)

for some constants $f^\min, f^\max$ and $\theta^\max > 0$. Thus the part of the $(\theta, f)$-space in which the $(\theta, f)$-pairs associated with the filter iterates lie is restricted to the rectangle

$$
\mathcal{M}_0 = [0, \theta^\max] \times [f^\min, f^\max],
$$

whose area, $\text{surf}(\mathcal{M}_0)$, is clearly finite.

We also note the following simple consequence of (2.11) and AS3.

\begin{lemma}
Suppose that Algorithm 2.1 is applied to problem (1.1). Suppose also that (2.11) and AS3 hold, that $k \in \mathcal{C}$, and that

$$
\theta_k \leq \delta_n.
$$

Then there exists a constant $\kappa_{\text{inc}} > 0$ independent of $k$ such that

$$
\kappa_{\text{inc}} \theta_k \leq \|n_k\|.
$$

(3.5)
\end{lemma}

\textbf{Proof.} Since $k \in \mathcal{C}$, we first obtain that $n_k$ exists (as a consequence of (2.11)), and define

$$
\mathcal{V}_k \overset{\text{def}}{=} \{ j \in \mathcal{E} \mid \theta_j = |c_j(x_k)| \} \cup \{ j \in \mathcal{I} \mid \theta_j = -c_j(x_k) \},
$$

that is the subset of most-violated constraints. From the definitions of $\theta_k$ in (2.2) and of the normal step in (2.7) we obtain, using the Cauchy-Schwartz inequality, that

$$
\theta_k \leq |\langle \nabla_x c_j(x_k), n_k \rangle| \leq \|\nabla_x c_j(x_k)\| \|n_k\|
$$

(3.6)

for all $j \in \mathcal{V}_k$. But AS3 ensures that there exists a constant $\kappa_{\text{inc}} > 0$ such that

$$
\max_{j \in \mathcal{E} \cup \mathcal{I}} \max_{x \in \mathcal{X}} \|\nabla_x c_j(x)\| \overset{\text{def}}{=} \frac{1}{\kappa_{\text{inc}}},
$$

\end{lemma}
We then obtain the desired conclusion by substituting this bound in (3.6).

Our assumptions and the definition of \( \chi_k \) in (2.14) ensure that \( \theta_k \) and \( \chi_k \) can be used (together) to measure criticality for problem (1.1).

**Lemma 3.2** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1 and AS3 hold, and that there exists a subsequence \( \{k_i\} \notin \mathcal{R} \) such that

\[
\lim_{i \to \infty} \theta_{k_i} = 0, \quad \lim_{i \to \infty} \chi_{k_i} = 0 \quad \text{and} \quad \lim_{k_i \to \infty} \pi_{k_i} = 0. \tag{3.7}
\]

Then every limit point of the sequence \( \{x_{k_i}\} \) is a first-order critical point for problem (1.1).

**Proof.** Consider \( x_* \), a limit point of the sequence \( \{x_{k_i}\} \), whose existence is ensured by AS3, and assume that \( \{k_i\} \subseteq \{k_i\} \) is the index set of a subsequence such that \( \{x_{k_{i,\ell}}\} \) converges to \( x_* \). If \( \{k_{i,\ell}\} \) contains infinitely many indices of \( \mathcal{A} \), the definition of \( \pi_k \) implies that \( x_* \) is a first-order critical point for problem (1.1). If this is not the case, the fact that \( k_{i,\ell} \notin \mathcal{R} \) implies that \( n_{k_{i,\ell}} \) satisfies (2.11) for sufficiently large \( \ell \) and converges to zero, because \( \{\theta_{k_{i,\ell}}\} \) converges to zero and the second part of this condition. As a consequence, we deduce from (2.12) that \( \{x_{k_{i,\ell}}^n\} \) also converges to \( x_* \). Since the minimization problem occurring in the definition of \( \chi_{k_{i,\ell}} \) (in (2.14)) is convex, we then obtain from classical perturbation theory (see, for instance, Fiacco, 1983, pp. 14-17), AS1 and the first part of (3.7) that

\[
| \min_{\mathcal{A}_\ell(x_*)=0, c_\ell(x_*)+A_\ell(x_*) \geq 0, \|t\| \leq 1} \langle g_*, t \rangle | = 0.
\]

This in turn guarantees that \( x_* \) is first-order critical for problem (1.1).

We start our analysis by examining what happens when an infinite number of iterates (that is, their \((\theta, f)\)-pairs) are added to the filter.

**Lemma 3.3** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1 and AS3 hold and that \( |Z| = \infty \). Then

\[
\lim_{k \to \infty} \theta_k = 0, \quad k \in Z
\]

**Proof.** Suppose, for the purpose of obtaining a contradiction, that there exists an infinite subsequence \( \{k_i\} \subseteq Z \) such that

\[
\theta_{k_i} \geq \epsilon \tag{3.8}
\]
for all $i$ and for some $\epsilon > 0$. At each iteration $k_i$, the $(\theta, f)$-pair associated with $x_k$, that is $(\theta_k, f_k)$, is added to the filter. This means that no other $(\theta, f)$-pair can be added to the filter at a later stage within the square

$$[\theta_k - \gamma \epsilon, \theta_k] \times [f_k, \gamma \epsilon, f_k],$$

or with the intersection of this square with $M_0$. But the area of each of these squares is $\gamma^2 \epsilon^2$. Thus the set $M_0$ is completely covered by at most a finite number of such squares. This puts a finite upper bound on the number of iterations in $\{k_j\}$, and the conclusion follows.

We next examine the size of the constraint violation before and after a "composite iteration" where restoration did not occur.

**Lemma 3.4** Suppose that Algorithm 2.1 is applied to problem (1.1). Suppose also that AS1 and AS3 hold and that $n_k$ satisfies (3.5) for $k \in C$. Then there exists a constant $\kappa_{\text{ubs}} > 0$ such that

$$\theta_k \leq \kappa_{\text{ubs}} \Delta_k^{1+\mu} \quad (3.9)$$

and

$$\theta(x_k + s_k) \leq \kappa_{\text{ubs}} \Delta_k^2. \quad (3.10)$$

for all $l \notin R$.

**Proof.** Assume first that $k \in C$ with $\mu_k = \mu$. Since $k \notin R$, we have from (3.5) and (2.13) that

$$\kappa_{\text{ins}} \theta_k \leq \|n_k\| \leq \kappa \Delta \mu \Delta_k^{1+\mu}, \quad (3.11)$$

which gives (3.9). On the other hand, (3.1) implies that an inequality of the form (3.9) holds for $k \in A$ or $k \in C$ with $\mu_k = 0$. Now, for any $k$, the $i$-th constraint function at $x_k + s_k$ can be expressed as

$$c_i(x_k + s_k) = c_i(x_k) + (e_i, A_k s_k) + \frac{1}{2} \langle s_k, \nabla_{xx} c_i(\xi_k) s_k \rangle,$$

for $i \in E \cup I$, where we have used AS1, the mean-value theorem, and where $\xi_k$ belongs to the segment $[x_k, x_k + s_k]$. Using AS3, we may bound the Hessian of the constraint functions and we obtain from (2.9), the Cauchy-Schwartz inequality, and (2.8) we have that

$$|c_i(x_k + s_k)| \leq \frac{1}{2} \max_{x \in X} \|\nabla_{xx} c_i(x)\| \|s_k\|^2 \leq \kappa_1 \Delta_k^2,$$

if $i \in E$, or

$$-c_i(x_k + s_k) \leq \frac{1}{2} \max_{x \in X} \|\nabla_{xx} c_i(x)\| \|s_k\|^2 \leq \kappa_1 \Delta_k^2,$$

if $i \in I$, where we have defined

$$\kappa_1 \equiv \frac{1}{2} \max_{i \in E \cup I} \max_{x \in X} \|\nabla_{xx} c_i(x)\|.$$

This gives the desired bound for any

$$\kappa_{\text{ubs}} \geq \max[\kappa_1, \kappa_{\text{ins}}, \kappa \Delta \mu / \kappa_{\text{ins}}].$$
We next assess the model decrease when the trust-region radius is sufficiently small.

\[ \chi_k \geq \epsilon \]  

(3.12)

Suppose furthermore that

\[ \Delta_k \leq \min \left[ 1, \frac{\epsilon}{\kappa_{umh}}, \left( \frac{2\kappa_{abg}}{\kappa_{umh} \kappa_{\Delta}} \right)^{\frac{1}{1+\mu}}, \left( \frac{\kappa_{\text{tmd}} \epsilon}{4\kappa_{abg} \kappa_{\Delta}} \right)^{\frac{1}{\mu}} \right] \overset{\text{def}}{=} \delta_m, \]  

(3.13)

where \( \kappa_{abg} \overset{\text{def}}{=} \max_{x \in X} \| \nabla_x f(x) \| \). Then

\[ m_k(x_k) - m_k(x_k + s_k) \geq \frac{1}{2} \kappa_{\text{tmd}} \epsilon \Delta_k. \]

This last inequality also holds if \( k \in A \), if (3.13) holds and

\[ \pi_k \geq \epsilon. \]  

(3.14)

**Proof.** Assume first that \( k \in C \). We note that, by (2.16), AS2, (3.12) and (3.13),

\[ m_k(x_k) - m_k(x_k + s_k) \geq \kappa_{\text{tmd}} \epsilon \chi_k \min \left[ \frac{\chi_k}{\kappa_{umh}}, \Delta_k \right] \geq \kappa_{\text{tmd}} \epsilon \Delta_k. \]  

(3.15)

Now

\[ m_k(x_k) = m_k(x_k) + \langle g_k, n_k \rangle + \frac{1}{2} \langle n_k, H_k n_k \rangle \]

and therefore, using the Cauchy-Schwartz inequality, AS2, (2.13) and (3.13) that

\[ |m_k(x_k) - m_k(x_k)| \leq \| n_k \|\| g_k \| + \frac{1}{2} \| H_k \|\| n_k \|^2 \]

\[ \leq \kappa_{abg} \| n_k \| + \frac{1}{2} \kappa_{umh} \| n_k \|^2 \]

\[ \leq \kappa_{abg} \kappa_{\Delta} \Delta_k^{1+\mu} + \frac{1}{2} \kappa_{umh} \kappa_{\Delta} \kappa_{\mu}^2 \Delta_k^{2(1+\mu)} \]

\[ \leq 2 \kappa_{abg} \kappa_{\Delta} \kappa_{\mu} \Delta_k^{1+\mu} \]

\[ \leq \frac{1}{2} \kappa_{\text{tmd}} \epsilon \Delta_k. \]

We thus conclude from this last inequality and (3.15) that the desired conclusion holds for \( k \in C \). If we now assume that \( k \in A \) (that is iteration \( k \) uses an alternative step), then (2.18), (3.13) and the inequality \( \kappa_{umh} \geq 1 \) directly yields that

\[ m_k(x_k) - m_k(x_k + s_k) \geq \kappa_{\text{tmd}} \min [\epsilon, \Delta_k] \geq \frac{1}{2} \kappa_{\text{tmd}} \Delta_k \]

as desired.
We continue our analysis by showing, as the reader has grown to expect, that iterations have to be very successful when the trust-region radius is sufficiently small.

**Lemma 3.6** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1–AS3, (2.16) and (3.12) hold, that $k \not\in \mathcal{R}$, and that
\[
\Delta_k \leq \min \left[ \delta_m, \frac{(1 - \eta_2)\kappa_{\text{umd}}\varepsilon}{2\kappa_{\text{obb}}} \right] \overset{\text{def}}{=} \delta_f. \tag{3.16}
\]
Then
\[
\rho_k \geq \eta_2.
\]

**Proof.** Using (2.21), (3.3), Lemma 3.5 and (3.16), we find that
\[
|\rho_k - 1| = \frac{|f(x_k + s_k) - m_k(x_k + s_k)|}{|m_k(x_k) - m_k(x_k + s_k)|} \leq \frac{\kappa_{\text{obb}}\Delta_k^2}{\frac{1}{2}\kappa_{\text{umd}}\varepsilon \Delta_k} \leq 1 - \eta_2,
\]
from which the conclusion immediately follows. $\square$

Note that this proof could easily be extended if the definition of $\rho_k$ in (2.21) were altered to be of the form
\[
\rho_k \overset{\text{def}}{=} \frac{f(x_k) - f(x_k + s_k) + \Theta_k}{m_k(x_k) - m_k(x_k + s_k)} \tag{3.17}
\]
provided $\Theta_k$ is bounded above by a multiple of $\Delta_k^2$. We will comment in Section 4 why such a modification might be of interest.

Now, we also show that the test (2.20) will always be satisfied when the trust-region radius is sufficiently small.

**Lemma 3.7** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1–AS3, (2.16) and (3.12) hold, that $k \not\in \mathcal{R}$, that $n_k$ satisfies (3.5) if $k \in \mathcal{C}$, and that
\[
\Delta_k \leq \min \left[ \delta_m, \left( \frac{\kappa_{\text{umd}}\varepsilon}{2\kappa_{\text{obb}}\kappa_\psi} \right)^{\frac{1}{(1 + \mu) - 1}} \right] \overset{\text{def}}{=} \delta_f. \tag{3.18}
\]
Then
\[
m_k(x_k) - m_k(x_k + s_k) \geq \kappa_\psi \theta_k^\psi.
\]

**Proof.** This directly results from the inequalities
\[
\kappa_\psi \theta_k^\psi \leq \kappa_\psi \kappa_\text{obb} \Delta_k^{\psi(1 + \mu)} \leq \frac{1}{2}\kappa_{\text{umd}}\varepsilon \Delta_k \leq m_k(x_k) - m_k(x_k + s_k),
\]
where we successively used Lemma 3.4, (3.18) and Lemma 3.5. $\square$
We may also guarantee a decrease in the objective function, large enough to ensure that the trial point is acceptable with respect to the \((\theta, f)\)-pair associated with \(x_k\), so long as the constraint violation is itself sufficiently small.

**Lemma 3.8** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1· AS3, (2.16), (3.12) and (3.16) hold, that \(k \not\in \mathcal{R}\), that \(n_k\) satisfies (3.5) if \(k \in \mathcal{C}\), and that

\[
\theta_k \leq -\frac{1}{\mu} \left( \frac{\eta_2 \kappa_{\text{ind}} \epsilon}{2 \gamma_0} \right)^{\frac{1+\mu}{\mu}} \overset{\text{def}}{=} \delta_\theta. \tag{3.19}
\]

Then

\[
f(x_k + s_k) \leq f(x_k) - \gamma_0 \theta_k.
\]

**Proof.** Applying Lemmas 3.4–3.6—which is possible because of (3.12), (3.16), \(k \not\in \mathcal{R}\) and \(n_k\) satisfies (3.5) for \(k \in \mathcal{C}\)—and (3.19), we obtain that

\[
f(x_k) - f(x_k + s_k) \geq \eta_2 [m_k(x_k) - m_k(x_k + s_k)] \\
\geq \frac{1}{2} \eta_2 \kappa_{\text{ind}} \epsilon \Delta_k \\
\geq \frac{1}{2} \eta_2 \kappa_{\text{ind}} \epsilon \left( \frac{\theta_k}{\kappa_{\text{ubt}}} \right)^{\frac{1}{1+\mu}} \\
\geq \gamma_0 \theta_k
\]

and the desired inequality follows. \(\Box\)

We now establish that if the trust-region radius and the constraint violation are both small at a non-critical iterate \(x_k\), TRQP\((x_k, \Delta_k)\) must be compatible.

**Lemma 3.9** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose that AS1· AS3, (2.11), and (3.12) hold, that (2.16) holds for \(k \not\in \mathcal{R}\), and that

\[
\Delta_k \leq \min \left[ \gamma_0 \delta_\rho, \left( \frac{1}{\kappa_\mu} \right)^{\frac{1}{\mu}}, \left( \frac{\gamma_0^2 (1 - \gamma_0) \kappa_{\Delta \kappa_\mu}}{\kappa_{\text{usc}} \kappa_{\text{ubt}}} \right)^{\frac{1}{1-\mu}} \right]. \tag{3.20}
\]

Suppose furthermore that

\[
\theta_k \leq \min[\delta_\theta, \delta_n]. \tag{3.21}
\]

Then \(k \not\in \mathcal{R}\).

**Proof.** If an alternative step is used at iteration \(k\), then \(k \not\in \mathcal{R}\). Assume therefore that \(k \not\in \mathcal{A}\). Because \(\theta_k \leq \delta_n\), we know from (2.11) and Lemma 3.1 that (2.11) and (3.5) hold. Moreover, since \(\theta_k \leq \delta_\theta\), we have that (3.19) also holds. Assume, for the purpose of deriving
a contradiction, that \( k \in \mathcal{R} \), which implies that
\[
\|\eta_k\| > \eta_\Delta k \Delta_k^{1+\mu},
\] 
(3.22)
where we have used (2.13) and the fact that \( \kappa_\mu \Delta_k^{1+\mu} \leq \kappa_\mu \Delta_k^\mu \leq 1 \) because of (3.20). In this case, the mechanism of the algorithm then ensures that \( k - 1 \not\in \mathcal{R} \). Now assume that iteration \( k - 1 \) is unsuccessful. Because of Lemmas 3.6 and 3.8, which hold at iteration \( k - 1 \not\in \mathcal{R} \) because of (3.20), the fact that \( \theta_k = \theta_{k-1} \), (2.11), and (3.19), we obtain that
\[
\rho_{k-1} \geq \eta_2 \text{ and } f(x_{k-1} + s_{k-1}) \leq f(x_{k-1}) - \gamma_\theta \theta_{k-1}.
\]
Hence, given that \( x_{k-1} \) is acceptable for the filter at the beginning of iteration \( k - 1 \), if this iteration is unsuccessful, it must be because
\[
\theta(x_{k-1} + s_{k-1}) > (1 - \gamma_\theta)\theta_{k-1} = (1 - \gamma_\theta)\theta_k.
\]
But Lemma 3.4 and the mechanism of the algorithm then imply that
\[
(1 - \gamma_\theta)\theta_k \leq \kappa_{\text{ubt}} \Delta_k^{2} \leq \frac{\kappa_{\text{ubt}}}{\gamma_\theta^2} \Delta_k^2.
\]
Combining this last bound with (3.22) and (2.11), we deduce that
\[
\kappa_\Delta k \Delta_k^{1+\mu} < \|\eta_k\| \leq \kappa_{\text{us}} \theta_k \leq \frac{\kappa_{\text{ubt}}}{\gamma_\theta^2} \frac{\kappa_{\text{us}} \kappa_{\text{ubt}}}{\gamma_\theta} \Delta_k^2
\]
and hence that
\[
\Delta_k^{1-\mu} > \frac{\gamma_\theta^2 (1 - \gamma_\theta) \kappa_{\Delta} \kappa_\mu}{\kappa_{\text{us}} \kappa_{\text{ubt}}}.
\]
Since this last inequality contradicts (3.20), our assumption that iteration \( k - 1 \) is unsuccessful must be false. Thus iteration \( k - 1 \) is successful and \( \theta_k = \theta(x_{k-1} + s_{k-1}) \). We then obtain from (3.22), (2.11) and (3.10) that
\[
\kappa_\Delta k \Delta_k^{1+\mu} < \|\eta_k\| \leq \kappa_{\text{us}} \theta_k \leq \kappa_{\text{us}} \kappa_{\text{ubt}} \Delta_k^{2} \leq \frac{\kappa_{\text{us}} \kappa_{\text{ubt}}}{\gamma_\theta^2} \Delta_k^2
\]
which is again impossible because of (3.20) and because \( 1 - \gamma_\theta < 1 \). Hence our initial assumption (3.22) must be false, which yields the desired conclusion. \( \square \)

We now distinguish two mutually exclusive cases. For the first, we consider what happens if there is an infinite subsequence of iterates belonging to the filter.

---

**Lemma 3.10** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1–AS3 and (2.11) hold and that (2.16) holds for \( k \not\in \mathcal{R} \). Suppose furthermore that \( |\mathcal{Z}| = \infty \). Then there exists an infinite subsequence \( \{k_j\} \subseteq \mathcal{Z} \) such that
\[
\lim_{j \to \infty} \theta_{k_j} = 0
\]
and
\[
\lim_{j \to \infty} \chi_{k_j} = 0 \quad \text{and} \quad \lim_{j \to \infty} \pi_{k_j} = 0.
\]
(3.24)
Proof. Let \{k_i\} be any infinite subsequence of \(Z\). We observe that (3.23) follows from Lemma 3.3. Suppose now that, for some \(\epsilon_2 > 0\),
\[
\chi_{k_i} \geq \epsilon_2
\]
for all \(i\) such that \(k_i \in C\) and
\[
\pi_{k_i} \geq \epsilon_2
\]
for all \(i\) such that \(k_i \in A\). Suppose furthermore that there exists \(\epsilon_3 > 0\) such that, for all \(i \geq i_0\),
\[
\Delta_{k_i} \geq \epsilon_3.
\] (3.27)
If \(k_i \not\in A\), (3.23) and (2.11) ensure that \(n_{k_i}\) exists for \(i \geq i_0\), say, and also that
\[
\lim_{i \to \infty} \|n_{k_i}\| = 0.
\] (3.28)
Thus (3.27) ensures that (2.13) holds for sufficiently large \(i\) and \(k_i \not\in R\). We may then decompose the model decrease in its normal and tangential components, that is
\[
m_{k_i}(x_{k_i}) - m_{k_i}(x_{k_i} + s_{k_i}) = m_{k_i}(x_{k_i}) - m_{k_i}(x_{k_i}^N) + m_{k_i}(x_{k_i}^N) - m_{k_i}(x_{k_i} + s_{k_i}).
\] (3.29)
Consider the normal component first. As we noted in the proof of Lemma 3.5,
\[
|m_{k_i}(x_{k_i}) - m_{k_i}(x_{k_i}^N)| \leq \kappa_{m,n}\|n_{k_i}\| + \frac{1}{2}\kappa_{m,n}\|n_{k_i}\|^2,
\]
which in turn, with (3.28), yields that
\[
\lim_{i \to \infty} |m_{k_i}(x_{k_i}) - m_{k_i}(x_{k_i}^N)| = 0.
\] (3.30)
If we now consider the normal component, (3.25), (3.27) (2.16) and AS2 yield that
\[
m_{k_i}(x_{k_i}^N) - m_{k_i}(x_{k_i} + s_{k_i}) \geq \kappa_{m,a}\|e_{\infty}\| \epsilon_2 \min\left[\frac{\epsilon_2}{\kappa_{m,n}}, \epsilon_3\right] \overset{\text{def}}{=} \delta_1 > 0.
\] (3.31)
Substituting (3.30) and (3.31) into (3.29), we find that, for \(k_i \in C\),
\[
m_{k_i}(x_{k_i}) - m_{k_i}(x_{k_i} + s_{k_i}) \geq \delta_1 > 0.
\]
If, on the other hand, \(k_i \in A\), then (3.26), (3.27) and (2.18) give that
\[
m_{k_i}(x_{k_i}) - m_{k_i}(x_{k_i} + s_{k_i}) \geq \kappa_{m,d}\|e_{\infty}\| \epsilon_3 \overset{\text{def}}{=} \delta_2 > 0.
\]
Thus
\[
\liminf_{i \to \infty}[m_{k_i}(x_{k_i}) - m_{k_i}(x_{k_i} + s_{k_i})] \geq \min[\delta_1, \delta_2] \overset{\text{def}}{=} \delta > 0.
\] (3.32)
We now observe that, because \(x_{k_i}\) is added to the filter at iteration \(k_i\), the mechanism of the algorithm imposes that either iteration \(k_i \in R\) or (2.20) must fail. Since we already verified that \(k_i \not\in R\) for \(i \geq i_0\) sufficiently large, we obtain that (2.20) must fail for such \(i\), that is
\[
m_{k_i}(x_{k_i}) - m_{k_i}(x_{k_i} + s_{k_i}) < \kappa_{\theta}^\psi_{k_i}.
\] (3.33)
Combining this bound with (3.32), we find that $\theta_k$ is bounded away from zero for $i$ sufficiently large, which is impossible in view of (3.23). We therefore deduce that (3.27) cannot hold and obtain that there is a subsequence $\{k_\ell\} \subseteq \{k_i\}$ for which

$$\lim_{\ell \to \infty} \Delta_{k_\ell} = 0.$$  

We now restrict our attention to the tail of this subsequence, that is to the set of indices $k_\ell$ that are large enough to ensure that (3.18), (3.19) and (3.20) hold, which is possible by definition of the subsequence and because of (3.23). For these indices, we may therefore apply Lemma 3.9, and deduce that iteration $k_\ell \not\in \mathcal{R}$ for $\ell$ sufficiently large. Hence, as above, (3.33) must hold for $\ell$ sufficiently large. However, we may also apply Lemma 3.7, which contradicts (3.33), and therefore (3.25) and (3.26) cannot hold together, yielding the desired result. □

Thus, if an infinite subsequence of iterates is added to the filter, Lemma 3.2 ensures that it converges to a first-order critical point. Our remaining analysis then naturally concentrates on the possibility that there may be no such infinite subsequence. In this case, no further iterates are added to the filter for $k$ sufficiently large. In particular, this means that the number of restoration iterations, $|\mathcal{R}|$, must be finite. In what follows, we assume that $k_0 \geq 0$ is the last iteration for which $x_{k_0-1}$ is added to the filter.

**Lemma 3.11** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1–AS3 and (2.11) hold and that (2.16) holds for $k \not\in \mathcal{R}$. Then we have that

$$\lim_{k \to \infty} \theta_k = 0. \quad (3.34)$$

Furthermore, $n_k$ exists and satisfies (3.5) for all $k \geq k_0$ sufficiently large.

**Proof.** Consider any successful iterate with $k \geq k_0$. Then we have that

$$f(x_k) - f(x_{k+1}) \geq \eta_1 [m_k(x_k) - m_k(x_k + s_k)] \geq \eta_1 \kappa_\delta \theta_k^\psi \geq 0. \quad (3.35)$$

Thus the objective function does not increase for all successful iterations with $k \geq k_0$. But AS1 and AS3 imply (3.4) and therefore we must have, from the first part of this statement, that

$$\lim_{k \in \delta} f(x_k) - f(x_{k+1}) = 0. \quad (3.36)$$

(3.34) then immediately follows from (3.35) and the fact that $\theta_j = \theta_k$ for all unsuccessful iterations $j$ that immediately follow the successful iteration $k$, if any. The last conclusion then results from (2.11) and Lemma 3.1. □

We now show that the trust-region radius cannot become arbitrarily small if the (asymptotically feasible) iterates stay away from first-order critical points.
Lemma 3.12 Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1--AS3 hold and that (2.16) holds for $k \notin \mathcal{R}$. Suppose furthermore that (3.12) hold for all $k \geq k_0$. Then there exists a $\Delta_{\min} > 0$ such that

$$\Delta_k \geq \Delta_{\min}$$

for all $k$.

Proof. Suppose that $k_1 \geq k_0$ is chosen sufficiently large to ensure that (3.21) holds and thus that (2.11) also holds for all $k \geq k_1$, which is possible because of Lemma 3.11. Suppose also, for the purpose of obtaining a contradiction, that iteration $j$ is the first iteration following iteration $k_1$ for which

$$\Delta_j \leq \gamma_0 \min \left[ \delta, \sqrt{\frac{(1 - \gamma_0)\theta^r}{\kappa_{\text{init}}}}, \Delta_{k_1} \right] \overset{\text{def}}{=} \gamma_0 \delta_s,$$

(3.37)

where

$$\theta^r \overset{\text{def}}{=} \min_{i \in \mathcal{Z}} \theta_i$$

is the smallest constraint violation appearing in the filter. Note also that the inequality $\Delta_j \leq \gamma_0 \Delta_{k_1}$, which is implied by (3.37), ensures that $j \geq k_1 + 1$ and hence that $j - 1 \geq k_1$ and thus that $j - 1 \notin \mathcal{R}$. Then the mechanism of the algorithm and (3.37) imply that

$$\Delta_{j-1} \leq \frac{1}{\gamma_0} \Delta_j \leq \delta_s$$

(3.38)

and Lemma 3.6, which is applicable because (3.37) and (3.38) together imply (3.16) with $k$ replaced by $j - 1$, then ensures that

$$\rho_{j-1} \geq \eta_2.$$  

(3.39)

Furthermore, since $n - j - 1$ satisfies (2.11), Lemma 3.1 implies that we can apply Lemma 3.4. This together with (3.37) and (3.38), gives that

$$\theta(x_{j-1} + s_{j-1}) \leq \kappa_{\text{init}} \Delta_{j-1}^2 \leq (1 - \gamma_0)\theta^r.$$  

(4.40)

We may also apply Lemma 3.8 because (3.37) and (3.38) ensure that (3.16) holds and because (3.19) also holds for $j - 1 \geq k_1$. Hence we deduce that

$$f(x_{j-1} + s_{j-1}) \leq f(x_{j-1}) - \gamma_0 \theta_{j-1}.$$  

This last relation and (4.40) ensure that $x_{j-1} + s_{j-1}$ is acceptable for the filter and $x_{j-1}$. Combining this conclusion with (3.39) and the mechanism of the algorithm, we obtain that $\Delta_j \geq \Delta_{j-1}$. As a consequence, and since (2.20) also holds at iteration $j - 1$, iteration $j$ cannot be the first iteration following $k_1$ for which (3.37) holds. This contradiction shows that $\Delta_k \geq \gamma_0 \delta_s$ for all $k > k_1$, and the desired result follows if we define

$$\Delta_{\min} = \min[\Delta_0, \ldots, \Delta_{k_1}, \gamma_0 \delta_s].$$

\[ \square \]
We may now analyze the convergence of \( \chi_k \) itself.

**Lemma 3.13** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1–AS3, (2.11) hold, and that (2.16) holds for \( k \not\in \mathcal{R} \). Then there exists a subsequence \( \{k_j\} \) such that

\[
\liminf_{j \to \infty} \chi_{k_j} = 0 \quad \text{and} \quad \liminf_{j \to \infty} \pi_{k_j} = 0.
\] (3.41)

**Proof.** We start by observing that Lemma 3.11 implies that the second conclusion of (2.11) holds for \( k \) sufficiently large. Moreover, as in Lemma 3.11, we obtain (3.35) and therefore (3.36) for each \( k \in \mathcal{S}, k \geq k_0 \). Suppose now, for the purpose of obtaining a contradiction, that (3.12) and (3.14) hold. Assume first that \( k \in \mathcal{C} \). In this case, and notice that

\[
m_k(x_k) - m_k(x_k + s_k) = m_k(x_k) - m_k(x_k^n) + m_k(x_k^n) - m_k(x_k + s_k).
\] (3.42)

Moreover, note, as in Lemma 3.5, that

\[
|m_k(x_k) - m_k(x_k^n)| \leq \kappa_{\text{us}} \|n_k\| + \kappa_{\text{amb}} \|n_k\|^2,
\]

which in turn yields that

\[
\lim_{k \to \infty} |m_k(x_k) - m_k(x_k^n)| = 0
\]

because of Lemma 3.11 and the second conclusion of (2.11). This limit, together with (3.35), (3.36) and (3.42), then gives that

\[
\lim_{k \to \infty} m_k(x_k^n) - m_k(x_k + s_k) = 0.
\] (3.43)

But (2.16), (3.12), AS2 and Lemma 3.12 together imply that, for all \( k \geq k_0 \)

\[
m_k(x_k^n) - m_k(x_k + s_k) \geq \kappa_{\text{m}} \chi_k \min \left[ \frac{\chi_k}{\beta_k}, \Delta_k \right] \geq \kappa_{\text{m}} \epsilon \min \left[ \frac{\epsilon}{\kappa_{\text{amb}}}, \Delta_{\min} \right],
\] (3.44)

immediately giving a contradiction with (3.43).

On the other hand, if \( k \in \mathcal{A} \), then (3.14) and (2.18) immediately imply that

\[
m_k(x_k) - m_k(x_k + s_k) \geq \kappa_{\text{m}} \min[\epsilon, \Delta_{\min}] > 0,
\]

which, together with (2.21) and the fact that \( k \in \mathcal{S} \), contradicts the boundedness of \( f \). Hence (3.12) and (3.14) cannot hold together and the desired result follows. \( \square \)

We may summarize all of the above in our main global convergence result.
**Theorem 3.14** Suppose that Algorithm 2.1 is applied to problem (1.1) and that finite termination does not occur. Suppose also that AS1–AS3 and (2.11) hold, and that (2.16) holds for $k \notin {\mathcal R}$. Let \( \{x_k\} \) be the sequence of iterates produced by the algorithm. Then either the restoration procedure terminates unsuccessfully by converging to an infeasible first-order critical point of problem (2.17), or there is a subsequence \( \{k_j\} \) for which

\[
\lim_{j \to \infty} x_{k_j} = x_*
\]

and \( x_* \) is a first-order critical point for problem (1.1).

**Proof.** Suppose that the restoration iteration always terminates successfully. From AS3, Lemmas 3.10, 3.11 and 3.13, we obtain that, for some subsequence \( \{k_j\} \),

\[
\lim_{j \to \infty} \theta_{k_j} = \lim_{j \to \infty} \chi_{k_j} = \lim_{j \to \infty, k_j \in A} \pi_{k_j} = 0. \tag{3.45}
\]

The conclusion then follows from Lemma 3.2. \( \square \)

Can we dispense with AS3 to obtain this result? Firstly, this assumption ensures that the objective and constraint functions remain bounded above and below (see (3.4)). This is crucial for the rest of the analysis because the convergence of the iterates to feasibility depends on the fact that the area of the filter is finite. Thus, if AS3 does not hold, we have to verify that (3.4) holds for other reasons. The second part of this statement may be ensured quite simply by initializing the filter to \((\theta^{\max}, -\infty)\), for some \( \theta^{\max} > \theta_0 \), in Step 0 of the algorithm. This has the effect of putting an upper bound on the infeasibility of all iterates, which may be useful in practice. However, this does not prevent the objective function from being unbounded below in

\[
{\mathcal C}(\theta^{\max}) = \{x \in \mathbb{R}^n \mid \theta(x) \leq \theta^{\max}\}
\]

and we cannot exclude the possibility that a sequence of infeasible iterates might both continue to improve the value of the objective function and satisfy (2.20). If \( C(\theta^{\max}) \) is bounded, AS3 is most certainly satisfied. If this is not the case, we could assume that

\[
f^{\min} \leq f(x) \leq f^{\max} \text{ and } 0 \leq \theta(x) \leq \theta^{\max} \text{ for } x \in C(\theta^{\max}) \tag{3.46}
\]

for some values of \( f^{\min} \) and \( f^{\max} \) and simply monitor that the values \( f(x_k) \) are reasonable—in view of the problem being solved—as the algorithm proceeds. To summarize, we may replace AS1 and AS3 by the following assumption.

**AS4:** The functions \( f \) and \( c \) are twice continuously differentiable on an open set containing \( C(\theta^{\max}) \), their first and second derivatives are uniformly bounded on \( C(\theta^{\max}) \), and (3.46) holds.

The reader should note that AS4 no longer ensures the existence of a limit point, but only that (3.45) holds for some subsequence \( \{k_j\} \). Furthermore, the comments following the statement of (2.11) no longer apply if limit points at infinity are allowed.
4 Conclusion and Perspectives

We have introduced a hybrid trust-region SQP-filter algorithm for general nonlinear programming, that mixes composite steps with potentially cheaper alternative steps, and we have shown this algorithm to be globally convergent to first-order critical points. This hybrid algorithm has the potential of being numerically more efficient than its version that only uses composite steps, as analyzed in Fletcher et al. (1999). However, the authors are well aware that this potential must be confirmed by numerical experiments.
