Abstract.

For the case of a first-class constrained system with equivariant momentum map, we study the conditions under which the double process of reducing to the constraint surface and dividing out by the group of gauge transformations $G$ is equivalent to the single process of dividing out the initial phase space by the complexification $G_\mathbb{C}$ of $G$. For the particular case of a phase space action that is the lift of a configuration space action, conditions are found under which, in finite dimensions, the physical phase space of a gauge system with first-class constraints is diffeomorphic to a manifold imbedded in the physical configuration space of the complexified gauge system. Similar conditions are shown to hold in the infinite-dimensional example of Yang-Mills theories. As a physical application we discuss the adequateness of using holomorphic Wilson loop variables as (generalized) global coordinates on the physical phase space of Yang-Mills theory.

1 Introduction

Complex gauge theories, i.e. theories with a complex group of gauge transformations, have recently appeared in several physical applications. The Hamiltonian (constraint) equations of $3 + 1$ general relativity simplify significantly when written in terms of the $SL(2, \mathbb{C})$-Ashtekar connection and its canonically conjugate variable, the densitized triad [6]. On the other hand, it has been shown that general relativity with a positive cosmological constant in $2 + 1$ dimensions corresponds to a Chern-Simons theory with gauge group $SL(2, \mathbb{C})$ [23].

Motivated by these examples, we study the geometric properties of a wide class of complex gauge theories obtained by the “complexification” of real gauge theories. Most of our rigorous analysis takes place in finite dimensions, where the analogous setting is that of hamiltonian gauge models with first-class constraints. In the infinite-dimensional case we prove our main result for Yang-Mills theories with a compact structure group.

Our investigation is purely kinematical and concerns properties of the big and reduced phase and configuration spaces. In the case of phase spaces that are cotangent bundles and where the action of the group of gauge transformations is the lift of an action on configuration space, it is shown that under reasonable conditions the physical phase space of the real, kinematic gauge theory $(Q, L_G, Q_\text{ph} = Q / L_G)$ is diffeomorphic (see Th.3 and Th.5) to an open submanifold $C^{\text{real}} / L_{G\text{r}}$ of the physical configuration space $Q^{\text{r}}$ of the complex gauge theory $(Q^{\text{r}}, L_{G\text{r}}, Q_{\text{ph}}^{\text{r}})$, which is the complexification of $(Q, L_G, Q_\text{ph})$ (see Def.1). This result is shown to hold also in the more general case of phase spaces where the action of the group of gauge transformations $G$ possesses an equivariant momentum map.

The action of the real group $G$ on the phase space $\mathcal{P}$ is extended to an action of $G^{\text{r}}$ by having the imaginary generators act appropriately in the directions orthogonal to the constraint surfaces. Note that the action of $G^{\text{r}}$ will in general be symplectic only if we restrict it to the real subgroup $G$.

When the saturation $C^{\text{sat}}$ (containing all points of $\mathcal{P}$ that can be reached from the constraint surface $C$ by a complex gauge transformation) is dense in $Q^{\text{r}}$ - which was the case in all examples studied - the above-mentioned diffeomorphism implies that in order to find the physical, reduced phase space for the system under consideration, the double process of restricting to the constraint surface $C \subset \mathcal{P}$ and dividing out by the real gauge transformations is equivalent to dividing out by the complex gauge transformations. This is in accordance with the expectation that the complex gauge orbits have twice the dimension of the real gauge orbits.

An analogous result for Chern-Simons theory was proven in [15], namely, that the cotangent bundle of the physical phase space of a Chern-Simons theory with compact gauge group $K$ is diffeomorphic to a dense submanifold in the physical phase space of the theory with complex gauge group $K^{\text{r}}$ [23].

The equivalence between the physical phase space $\mathcal{P}_{\text{ph}}$ of the real gauge theory and the physical configuration space $Q_{\text{ph}}^{\text{r}}$ of the complex gauge theory may play an important role for both theories. On the one hand, the quantization of the complex theory, by analogy with the Palatini theories [8], is expected to be facilitated by the existence of
additional structures in $Q^\alpha_{ph}$, induced from $P_{ph}$. It also allows us in principle to relate the
Hilbert spaces associated with the quantization of the complex theory with the better-
derstood Hilbert spaces of the quantization of the real theory (an example is given
by the generalization to a complex gauge group of the Chern-Simons theory in $2 + 1$
dimensions by Witten [21]). On the other hand, global (generalized) coordinates in $Q^\alpha_{ph}$
may be used in $P_{ph}$. This motivates the use of “holomorphic Wilson loop variables”
as global coordinates on the physical phase space of Yang-Mills theories with real gauge
groups, and gives further justification to the use of such variables in general relativity,
written in the Ashtekar variables (cf. Sec.5).

We do not address here the general question of how a dynamical principle can be
incorporated into our framework. Standard hamiltonians for gauge theories may not be
physically meaningful in the complexified theory. For example, it is well-known that
the usual Yang-Mills action proportional to $Tr FF$ for a complex gauge group $G$ leads
to a non-positive energy. Note also that the theories we cited at the beginning of the
introduction are examples of so-called generally covariant theories, whose particular
properties render them meaningful in spite of the presence of complex structures. Fur-
thermore, as illustrated by the example of $3 + 1$ gravity in terms of Ashtekar variables,
it may be necessary to complement the theory by a set of reality conditions, projecting
out the sector of physical states.

The present work is organized as follows. In Sec.2 we describe the class of gauge
theories under study. The main result relating $P_{ph}$ and $Q^\alpha_{ph}$ (i.e. $P/LG$) is formulated
and proven in Sec.3. In Sec.4 we study three illustrative finite-dimensional examples,
with the groups of gauge transformations $G = IR^n$, $G = SO(n)$, and $G = U(n)$ re-
spectively. The latter is an example of an action that is not the lift of a configuration
space action. Its physical phase space is a complex Grassmann manifold. In Sec.5 we
demonstrate that our techniques are applicable on the infinite-dimensional phase space
of Yang-Mills theory on an arbitrary three-dimensional compact and oriented manifold.
We also comment on how general relativity in terms of the Ashtekar variables can be
viewed in the same framework. In Sec.6 we present our conclusions.

2 Gauge theories in the hamiltonian formalism

In order to set the stage for the field theoretic application, we first study the geometry of
the analogous finite-dimensional hamiltonian systems with symmetry which, in Dirac’s
terminology, are gauge models with a set of first-class constraints.

Let the finite-dimensional manifold $Q$ be the “big” configuration space of such a
gauge system, and let $L_G$ denote a proper, but not necessarily free action of a Lie group
$G$ as the group of gauge transformations on $Q$. (Recall that an action $L_G$ is called
proper if the inverse images of compact sets under the map $(g, x) \rightarrow (L_g x, x)$ are again
compact.) Assuming that $Q/L_G$ (possibly after excluding singular orbits from $Q$) has
the structure of a differentiable manifold, this quotient space is known as the physical
configuration space of the system,
\[ Q_{ph} = Q/L_G. \]

The resulting triplet
\[ (Q, L_G, Q_{ph}) \]
will be called a kinematic gauge theory. In our current investigation we will not address the question of how a physical, gauge-invariant dynamics can be introduced into this setting in a meaningful way.

The big phase space of the gauge theory (2) is the cotangent bundle \( P = T^* Q \), with the canonical symplectic form \( \Omega \). The gauge transformations of the big configuration space, \( L_g, g \in G \), lift uniquely to symplectic (\( \Omega \)-preserving) gauge transformations \( \tilde{L}_g, g \in G \), of \( P \). Note that our results also apply when the phase space \( P \) is not of the form of a cotangent bundle and/or the symplectic action of the symmetry group \( G \) is not the lift of an action on the configuration space (c.f. Sec.4.3).

We will now introduce the notion of a momentum map \([1, 14, 3]\), which is a useful tool in the abstract formulation of hamiltonian systems with symmetry. The components of the momentum map are just the conserved quantities associated with that symmetry (for example, the components of the angular momentum of a particle in the presence of rotational symmetry). For gauge systems, the conserved quantities are the first-class constraints, which are required to vanish for physical configurations. The constraints define a submanifold in phase space, the so-called constraint surface \( C \), which can alternatively be described as the zero level set of the corresponding momentum map.

For the class of gauge systems with action \( \tilde{L}_G \) we are considering, the momentum map \( \mu : P \rightarrow G^* \) (\( G^* \) denoting the dual of the Lie algebra \( G \) of \( G \)) always exists and is constructed as follows: for each algebra element \( \xi \in G \), let the vector field \( \xi^P \in \mathcal{X}(P) \) be the infinitesimal generator of the action \( \tilde{L}_G \) associated to \( \xi \),
\[ \xi^P(p) = \frac{d}{dt} \Big|_{t=0} \tilde{L}_{\exp(t\xi)} \ p, \quad \forall p \in P. \]

Each such \( \xi^P \) is a globally hamiltonian vector field on \( P \), with hamiltonian function \( \mu^\xi : P \rightarrow \mathbb{R} \) given by
\[ \mu^\xi(\alpha_q) = \alpha_q(\xi^Q(q)), \quad \forall \alpha_q = p \in T^* Q, \]
where \( \xi^Q \) is the infinitesimal generator of gauge transformations on \( Q \), and we have identified a phase space point \( p \) with the corresponding one-form \( \alpha \) on \( Q \), where \( \alpha_q \in T_q^* Q \) with \( q = \tilde{\pi}(p) \) (\( \tilde{\pi} \) denoting the projection to the base space \( Q \)). Here \( \mu^\xi \) is of course the first-class constraint associated with the generator \( \xi \) of the group of gauge transformations.

We now collect the maps \( \mu^\xi \) into a unique momentum map \( \mu : P \rightarrow G^* \) by defining, for all \( p \in P \) and \( \xi \in G \)
\[ \mu(p) \cdot \xi := \mu^\xi(p), \]
where • denotes the duality between $\mathcal{G}$ and $\mathcal{G}^*$. The momentum map (4), (5) is $Ad^*$-equivariant [1], i.e.

$$Ad^*_{g^{-1}} \circ \mu = \mu \circ \tilde{L}_g \quad \forall g \in G.$$  \hfill (6)

This statement implies that the first-class constraints form a true Lie algebra with respect to the Poisson brackets on $\mathcal{P}$. In more general cases of phase spaces and symmetry group actions we will assume that the $G$-action has an $Ad^*$-equivariant momentum map.

To obtain the physical phase space of the kinematic gauge theory $(Q, L_G, \mathcal{P}_{ph})$, we must use the momentum map twice. We first have to restrict the phase space $\mathcal{P}$ to the constraint surface $\mathcal{C}$, defined as the zero level set of the momentum map,

$$\mathcal{C} = \{ p \in \mathcal{P} : \mu(p) = 0 \}. \hfill (7)$$

Furthermore, by equivariance the components $\mu^\xi$ of the momentum map generate gauge transformations $\tilde{L}_g$ on $\mathcal{C}$, hence to obtain the physical phase space $\mathcal{P}_{ph}$ we have to perform the quotient

$$\mathcal{P}_{ph} = \mathcal{C}/\tilde{L}_G. \hfill (8)$$

In the present paper we show that in some physically relevant cases the double process in phase space of constraining to $\mathcal{C}$ and quotienting out by the real gauge group action of $G$ is equivalent to the one-stage process of quotienting out by an appropriate action of the complex group $G_{\mathbb{C}}$.

Recall that for the setting described above and for the case that the group $G$ acts freely on $\mathcal{P}$, the following reduction theorem holds (see, for example, [17] and references therein; the present formulation is taken from [1], Theorem 4.3.1):

**Theorem 1** Let $(\mathcal{P}, \Omega)$ be a symplectic manifold on which the Lie group $G$ acts symplectically and let $\mu : \mathcal{P} \to \mathcal{G}^*$ be an $Ad^*$-equivariant momentum map for this action. Assume $x \in \mathcal{G}^*$ is a regular value of $\mu$ (i.e. for every $p \in \mu^{-1}(x)$, $dp_x$ is surjective), and that the isotropy group $G_x$ under the $Ad^*$-action on $\mathcal{G}^*$ acts freely and properly on $\mu^{-1}(x)$. Then $\mathcal{P}_x = \mu^{-1}(x)/\tilde{L}_G$, has a unique symplectic form $\omega_x$ with the property $\pi_x^* \omega_x = i_x^* \Omega$, where $\pi_x : \mu^{-1}(x) \to \mathcal{P}_x$ is the canonical projection and $i_x : \mu^{-1}(x) \to \mathcal{P}$ is the inclusion.

There is an analogous result if $x \in \mathcal{G}^*$ is only a weakly regular value of $\mu$ (i.e. $\mu^{-1}(x)$ is a submanifold with $T_p \mu^{-1}(x) = \ker dp_x$), the group $G_x$ therefore does not act freely, the $G_x$-orbits in $\mu^{-1}(x)$ are all of the same type, and hence the dimension of the isotropy group $G_p$ constant for all points $p \in \mu^{-1}(x)$). Moreover, if the $G$-action on $Q$ is proper and free, one can prove that [13]

$$\mathcal{P}_{ph} = \mathcal{C}/\tilde{L}_G \cong T^*(Q/L_G)$$  \hfill (9)

i.e. the reduced physical phase space $\mathcal{P}_{ph} = \mathcal{C}/G$, given by the above theorem, is symplectomorphic to the cotangent space $T^*Q_{ph}$ of the reduced physical configuration space $Q_{ph} = Q/L_G$. Under appropriate regularity conditions, an analogous result holds for the case that the action is non-free [20], the standard action of $SO(n)$ on $\mathbb{R}^n$ being the prototypical example (cf. Sec.4.2).
3 Complexification of gauge theories

A complex Lie group $H$ is a Lie group which at the same time is a complex manifold [16]. The two structures are related by demanding that the map
\[ H \times H \rightarrow H \]
\[ (h_1, h_2) \mapsto h_1 h_2^{-1} \]
be holomorphic.

So far we have considered the general case of triplets $(Q, L_G, Q_{ph})$, without specifying whether the group $G$ is real or complex. We will call such a gauge theory complex if the group $G$ of gauge transformations is a complex Lie group. It is convenient to introduce the concept of the “complexification” of a kinematic gauge theory:

**Definition 1** The kinematic gauge theory $(Q^\mathbb{C}, L_{G^\mathbb{C}}, Q_{ph}^\mathbb{C})$ is called a complexification of the theory $(Q, L_G, Q_{ph})$ if it satisfies the following three conditions:

1. The complex configuration space is diffeomorphic to the real phase space,
\[ Q^\mathbb{C} \cong \mathcal{P}(\equiv T^*Q). \tag{10} \]

2. The complex gauge group can be uniquely written in the form
\[ G^\mathbb{C} = G e^{i\theta}. \tag{11} \]

   In case the group $G$ is compact, $G^\mathbb{C}$ is called the universal complexification of $G$, and $G$ is its maximal compact subgroup [16].

3. Using the diffeomorphism (10), the restriction of the complex action of $G^\mathbb{C}$ to its real subgroup $G$ coincides with the lift of the $L_G$-action,
\[ L_{G^\mathbb{C}} G = \hat{L}_G. \tag{12} \]

This definition is motivated by the fact that the configuration space of a Yang-Mills theory with complexified structure group $K^\mathbb{C}$ satisfies (10), (11) and (12), and hence can be regarded as the complexification of a Yang-Mills theory with structure group $K$ (cf. Sec.5). - In the present paper we study the conditions under which the equation (10) holds at the level of the reduced spaces (if a complexification of $(Q, L_G, Q_{ph})$ exists), i.e. when we have
\[ Q_{ph}^\mathbb{C} \cong \mathcal{P}_{ph}, \tag{13} \]
where $\mathcal{P}_{ph}$ is defined by (8).

Consider now the (not necessarily unique) complexification $(Q^\mathbb{C}, L_{G^\mathbb{C}}, Q_{ph}^\mathbb{C})$ of the kinematic gauge theory $(Q, L_G, Q_{ph})$. The action of $G^\mathbb{C}$ on $\mathcal{P}$ defines a homomorphism $\tau$ of Lie algebras from the complexified Lie algebra $\mathfrak{g}_{G^\mathbb{C}}$ into the vector fields on $\mathcal{P}$,
\[ \tau : \mathfrak{g}_{G^\mathbb{C}} = \mathfrak{g} + i \mathfrak{g} \rightarrow \mathcal{X}(\mathcal{P}) \]
\[ \tau(\xi + i\eta) = \xi^\mathcal{P} + (i\eta)^\mathcal{P}, \quad \xi, \eta \in \mathfrak{g}. \tag{14} \]

We will assume that $\mathcal{P}$ and $L_{G^\mathbb{C}}$ are such that the following conditions hold:
Conditions 1

- There exists a symplectic almost-complex structure $J$ on $\mathcal{P}$ such that
  \[(i\eta)^\mathcal{P} = J\eta^\mathcal{P}, \quad \forall \eta \in \mathcal{G}.\] (15)

- The non-degenerate symmetric tensor $\gamma$ on $\mathcal{P}$ defined by $\Omega$ and $J$ through
  \[\gamma(X,Y) := \Omega(X,JY)\] (16)

  is a Riemannian metric, i.e. $\mathcal{P}$ is a quasi-Kähler manifold.

There are a number of conclusions that can be drawn from the existence on $\mathcal{P}$ of an almost-complex structure $J$ and a Riemannian metric $\gamma$ that intertwine with the symplectic structure according to (16):

- For all linear subspaces $S \subset T_p\mathcal{P}$ we have
  \[J(S^\perp) = S^\circ\] (17)

  where $S^\perp$ denotes the subspace ($\gamma$-)orthogonal and $S^\circ$ the subspace polar symplectic (or, $\Omega$-orthogonal,) to $S$.

- Denoting by $\nabla^\xi$ the gradient vector field with respect to $\gamma$ of the constraint function $\mu^\xi : \mathcal{P} \to R$,
  \[d\mu^\xi(Y) = \gamma(\nabla^\xi, Y), \quad \forall Y \in \mathcal{X}(\mathcal{P}),\] (18)

  we have
  \[\nabla^\xi = J\xi^\mathcal{P},\] (19)

  i.e. the vector space perpendicular to a surface $\mu =$const. is obtained by applying the complex structure $J$ to the infinitesimal gauge generators $\xi^\mathcal{P}$. In fact, using (18) and the fundamental relation (16), one derives for all $Y \in \mathcal{X}(\mathcal{P})$
  \[\gamma(\nabla^\xi, Y) = d\mu^\xi(Y) = \Omega(\xi^\mathcal{P}, Y) = \gamma(J\xi^\mathcal{P}, Y).\] (20)

- For each point $p \in \mathcal{P}$, define a map $\nabla_{\mu_p} : \mathcal{G} \to T_p\mathcal{P}$ by
  \[\nabla_{\mu_p}(\xi) = \nabla^\xi(p) = J\xi^\mathcal{P}(p).\] (21)

  Identifying the tangent space $T_p\mathcal{P}$ with the cotangent space $T^*_p\mathcal{P}$ via the Riemannian metric $\gamma$, we see that the map $\nabla_{\mu_p} : \mathcal{G} \to T_p\mathcal{P}$ is the adjoint of the map $d\mu_p : T_p\mathcal{P} \to \mathcal{G}^*$.

- It is easy to verify that
  \[T_p(\tilde{L}_G \cdot p) = (\text{Ker } d\mu_p)^g = J(\text{Im } \nabla_{\mu_p})\] (22)

  and
  \[\text{Ker } (\nabla_{\mu_p}) = \mathcal{G}_p\] (23)

  where $\tilde{L}_G \cdot p$ denotes the $G$-orbit through the point $p \in \mathcal{P}$, and $\mathcal{G}_p$ the Lie algebra of the isotropy group $G_p$ at $p$.
Thus, if the pair \((L_G, \mathcal{P})\) satisfies \textit{Cond.1}, the imaginary generators of \(G_\mathcal{P}\) are represented by vector fields \(\gamma\)-orthogonal to the surfaces \(\mu = \text{const.}\). Note that these vector fields \(J\xi\mathcal{P}\) are in general neither hamiltonian nor isometries.

Note furthermore that although the \(G\)-action on \(\mathcal{P}\) is proper, the \(G_\mathcal{P}\)-action need not be, which implies that the quotient \(Q^\mathcal{P}/L_G\) need not be Hausdorff. This of course can only occur since \(G_\mathcal{P}\) is a non-compact group. Although one can make sense of the case when the \(G\)-action is proper and the quotient space \(Q/L_G\) is an orbifold (i.e. no longer a smooth manifold) \([9]\), we are not aware of a treatment or a physical interpretation for the non-Hausdorff case. Our work may be viewed as a prescription of how to deal with such gauge systems, by selecting a sufficiently well-behaved subspace of \(Q^\mathcal{P}\).

Let us now recall the Moncrief decomposition for gauge systems \([18, 4]\) which characterizes an orthogonal splitting of the tangent spaces \(T_p\mathcal{P}\), where \(p\) lies in the constraint surface \(\mathcal{C}\). Taking into account that

\[
T_p(\tilde{L}_G \cdot p) \subset \ker d\mu_p
\]

for all points \(p \in \mathcal{C}\), (17)-(23) can be summarized into the following theorem.

**Theorem 2** At all points \(p \in \mathcal{C} \subset \mathcal{P}\), the tangent space \(T_p\mathcal{P}\) admits the following (orthogonal) Moncrief decomposition:

\[
T_p\mathcal{P} = \ker d\mu_p \cap J(\ker d\mu_p) \oplus \text{Im} \nabla \mu_p \oplus J(\text{Im} \nabla \mu_p)
\]

the first summand being symplectic, and the last two isotropic.

At a given point \(p \in \mathcal{C}\), the Moncrief decomposition (25) of \(T_p\mathcal{P}\) has the following geometric interpretation:

- \((1) = \ker d\mu_p \cap J(\ker d\mu_p)\) can be naturally identified with the tangent space \(T_{\pi(p)}\mathcal{P}_{\mathcal{A}}\), and represents the true, physical degrees of freedom of the system.
- \((2) = \text{Im} \nabla \mu_p\) represents infinitesimal deformations orthogonal to the constraint surface \(\mathcal{C}\).
- \((3) = J(\text{Im} \nabla \mu_p) = T_p(\tilde{L}_G \cdot p)\) is the tangent space to the gauge directions, that is, to the \(G\)-orbit \(\tilde{L}_G \cdot p\) through \(p \in \mathcal{C}\).

Consider now the subset \(\mathcal{C}^{\text{sat}}\) of \(\mathcal{P}\) given by

\[
\mathcal{C}^{\text{sat}} := \{ L_g \cdot p : p \in \mathcal{C} \text{ and } g \in G_\mathcal{P} \}.
\]

We will call the set \(\mathcal{C}^{\text{sat}}\) the saturation of \(\mathcal{C}\) (\textit{with respect to the action of }\(G_\mathcal{P}\)). It consists of all points that can be reached from the constraint surface by a complex
gauge transformation. We prove below that $C^\text{sat}$ is open in $\mathcal{P}$ and conjecture that it is actually dense in $\mathcal{P}$. In Sec.4 we corroborate this conjecture by some examples.

The Moncrief decomposition (25) implies the “local” (in a neighbourhood of $C$) equivalence between $C^\text{sat}/L_{G_4}$ and $\mathcal{P}_{ph} = C/\tilde{L}_{G}$. The following propositions prove their global equivalence.

**Proposition 1** The saturation $C^\text{sat}$ is open in the phase space $\mathcal{P}$.

**Proof.** By virtue of the Moncrief decomposition, $\{\xi^\mathcal{P} : \xi \in i\mathcal{G}\} = Im \nabla \mu_p$ is a complementary subspace to $T_p\mathcal{C}$ in $T_p\mathcal{P}$. Therefore $C^\text{sat}$ contains an open neighbourhood $U$ of $C$ in $\mathcal{P}$. Moreover, since $C^\text{sat}$ is given by the union $C^\text{sat} = \bigcup_{p \in G_4} \{ L_{G_4} \cdot p \}$, it follows that the saturation $C^\text{sat}$ is open in $\mathcal{P}$. QED.

Now, since $C \subset C^\text{sat}$ and since each “real” orbit $\tilde{L}_{G} \cdot p$, $p \in C$ is contained in a “complex” orbit $L_{G_4} \cdot p$, we have a map

$$\mathcal{P}_{ph} = C/\tilde{L}_{G} \rightarrow C^\text{sat}/L_{G_4}.$$  \hspace{1cm} (27)

Since our aim is to prove the equivalence between the physical phase space and the complex quotient on the right-hand side, we must show that the map (27) is a bijection. Equivalently, we must prove that each “complex” orbit $L_{G_4} \cdot p$, $p \in C$, contains only one “real” orbit $L_{G} \cdot p$, i.e. that the following is true:

**Proposition 2**

$$\ (L_{G_4} \cdot p) \cap C = L_{G} \cdot p, \quad \forall p \in C.$$  \hspace{1cm} (28)

**Proof.** It suffices to prove that

$$\ (L_{G_4} \cdot p) \cap C \subset L_{G} \cdot p.$$  \hspace{1cm} (29)

Let $L_{G} \cdot p \in (L_{G_4} \cdot p) \cap C$, with $q \in G_4$. We must show that $L_{G} \cdot p = L_{h} \cdot p$, for some real group element $h \in G$. However, since $C$ is a $G$-invariant submanifold of $\mathcal{P}$ and $G_4 = G \exp(i\mathcal{G})$ by assumption, we can without loss of generality take $g$ to be of the form $g = \exp(i\xi)$, with $\xi \in \mathcal{G}$.

Hence assume that

$$L_{\exp(i\xi)} \cdot p = L_{eit} \cdot p \in C.$$  \hspace{1cm} (30)

Let us set $q_t := L_{eit} \cdot p$, and consider the function $f : [0, 1] \rightarrow \mathbb{R}$, defined by (see equation (5))

$$f(t) = \mu(\xi_q(t)).$$  \hspace{1cm} (31)

Then, $f(0) = \mu(p) = 0$, since $p \in C = \mu^{-1}(0)$, and also $f(1) = \mu(\xi_q(1)) = 0$, by assumption (30). On the other hand, using (14) and (16) we compute

$$f'(t) = d\mu(\xi_q)(J\xi^\mathcal{P}(q_t))$$
$$= \Omega_q(\xi^\mathcal{P}(q_t), J\xi^\mathcal{P}(q_t))$$
$$= \gamma(\xi^\mathcal{P}(q_t), \xi^\mathcal{P}(q_t)) \geq 0.$$  \hspace{1cm} (32)
Therefore, the function \( f \) must vanish on the entire interval \([0, 1]\), and \( q_t \in \mathcal{C} \), for all \( t \in [0, 1] \). Moreover we have, for all \( t \in [0, 1] \), \( \xi^p(q_t) = 0 \) which implies \( q_t = p \) and, in particular,

\[
 L_{q_t} \cdot p = p \in L_G \cdot p.
\]  

**QED.**

In conclusion, the map (27) is a bijection. Moreover, using the Moncrief decomposition and the inverse mapping theorem, one can easily prove that this map is in fact a (\( J \)-dependent) diffeomorphism. We have therefore proved our main result:

**Theorem 3** Let \( \tilde{L}_G \) be a proper symplectic action of the Lie group \( G \) on the symplectic manifold \( \mathcal{P} \), with an \( Ad^* \)-equivariant momentum map \( \mu \), and let \( L_{G_a} \) be a complexification of this action satisfying (11), (12) and Cond.1. If \( 0 \) is a weakly regular value of \( \mu \), the map (27) is a diffeomorphism between \( \mathcal{C}/\tilde{L}_G \) and \( \mathcal{C}^{\text{sat}}/L_{G_a} \), where \( \mathcal{C}^{\text{sat}} \) is given by (26).

Note that there may exist complex orbits in \( Q^\mathbb{C} \) which do not contain any real orbit \( \tilde{L}_G \cdot p, p \in \mathcal{C} \), i.e. not every complex orbit necessarily intersects the constraint surface (see examples 4.2 and 4.3). However, in the finite-dimensional examples we considered, \( \mathcal{C}^{\text{sat}} \) was always dense in \( \mathcal{P} \). We conjecture that this is the case for a wide class of systems and in particular for the Yang-Mills theory discussed in Sec.5.

Given the diffeomorphism between \( \mathcal{P}_{ph} \) and \( \mathcal{C}^{\text{sat}}/L_{G_a} \), we can now pull back to \( \mathcal{C}^{\text{sat}}/L_{G_a} \) the unique symplectic form on the physical phase space obtained from the Marsden-Weinstein reduction.

Conversely, we are interested in the question under what conditions a given kinematic gauge theory \((Q, L_G, Q_{ph})\) can be complexified. One necessary condition is that the vector fields \( J_\eta^\mathcal{P} \) (c.f. (15)) be complete, so that their infinitesimal action can be exponentiated. We also need a \( G \)-invariant almost complex structure \( J \) on the phase space \( \mathcal{P} \). This is not a very strong restriction, since for compact \( G \) one can always define a \( G \)-invariant almost-Kähler structure on \( \mathcal{P} \). The most important condition comes from demanding that the map \( \tau : G_{\mathbb{C}} \to \mathcal{K}(\mathcal{P}) \) constructed according to

\[
 \tau(\xi + i\eta) := \xi^\mathbb{C} + J\eta^\mathbb{C},
\]  

with \( \xi, \eta \in G \), define a homomorphism of Lie algebras (cf. expressions (14) and (15)). It turns out that this is the case only if the restriction of the almost-complex structure \( J \) to the complex \( G_{\mathbb{C}} \)-orbits in \( \mathcal{P} \) is integrable. All these conditions are satisfied for the finite-dimensional gauge systems discussed in the next section.

---

4 Finite-dimensional examples

4.1 Group of gauge transformations \( IR^n \)

We first consider an example with an abelian group of gauge transformations, the kinematic gauge model \((Q, L_G, Q_{ph}) = (IR^n, L_{IR^n}, IR^{m-n})\), where \( n < m \), with \( IR^n \) acting
freely on $\mathbb{R}^m$. The coordinates on the configuration space $Q$ are the $x_I$, $I = 1, \ldots, m$, and the $n$ algebra generators $\xi^i$ of the gauge group $\mathbb{R}^n$ are taken to act on $Q$ by the vector fields $\partial/\partial x_i$, $i = 1, \ldots, n$. The corresponding first-class constraints on $\mathcal{P} = T^* \mathbb{R}^m$ are given by $p_i = 0$, $i = 1, \ldots, n$, with the canonically lifted action on $\mathcal{P}$,

$$\xi^i \mapsto \frac{\partial}{\partial x_i}, \quad i = 1, \ldots, n.$$  \hspace{1cm} (35)

The $(2m - n)$-dimensional constraint surface $\mathcal{C}$ is given by

$$\mathcal{C} = \{ (\vec{x}, \vec{p}) \in \mathbb{R}^{2m} : p_i = 0, i = 1, \ldots, n \}.  \hspace{1cm} (36)$$

The physical phase space $\mathcal{P}_{ph}$ is the cotangent bundle $T^* \mathbb{R}^{m-n}$, parametrized by the $m-n$ coordinate pairs $(x_a, p_a)$, $a = n + 1, \ldots, m$, with the induced canonical symplectic form.

We are now looking for suitable complexifications of $(\mathbb{R}^m, L_{\mathbb{R}^n}, \mathbb{R}^{m-n})$. Consider the complex structure $J$ on $\mathcal{P}$ defined by

$$\begin{align*}
J \frac{\partial}{\partial x_I} &= \frac{\partial}{\partial p_I}, & J \frac{\partial}{\partial p_I} &= - \frac{\partial}{\partial x_I}, \quad I = 1, \ldots, m.
\end{align*} \hspace{1cm} (37)$$

We use this complex structure to extend the action of $\mathbb{R}^n$ to one of $(\mathbb{R}^n)_{\Psi} = \mathfrak{g}^n$ by representing the “imaginary” generators as

$$i \xi^j \mapsto J \frac{\partial}{\partial x_j} = \frac{\partial}{\partial p_j}, \quad j = 1, \ldots, n.  \hspace{1cm} (38)$$

If we now consider the kinematic gauge theory $(\mathfrak{q}^m, L_{\mathfrak{q}^n}, \mathfrak{q}^{m-n})$ with coordinates $z_I = x_I + ip_I$ on the complex configuration space $\mathfrak{q}^m$, and with the action of the gauge group $\mathfrak{g}^n$ defined by

$$\tau(\xi^i + i \xi^j) = \frac{\partial}{\partial x_i} + i \frac{\partial}{\partial p_j}, \quad i, j = 1, \ldots, n,  \hspace{1cm} (39)$$

by Def. 1 this is a complexification of the triplet $(\mathbb{R}^m, L_{\mathbb{R}^n}, \mathbb{R}^{m-n})$, under the diffeomorphism $z_I \to (x_I, p_I)$ between $\mathfrak{q}^m$ and $T^* \mathbb{R}^m$. Moreover, the symmetric tensor $\gamma$ on $\mathcal{P}$ constructed according to (16) is a well-defined Riemannian metric,

$$\gamma(\frac{\partial}{\partial x_I}, \frac{\partial}{\partial x_J}) = \Omega(\frac{\partial}{\partial x_I}, \frac{\partial}{\partial p_J}) = \delta_{IJ}$$

$$\gamma(\frac{\partial}{\partial x_I}, \frac{\partial}{\partial p_J}) = \Omega(\frac{\partial}{\partial x_I}, - \frac{\partial}{\partial x_J}) = 0$$

$$\gamma(\frac{\partial}{\partial p_I}, \frac{\partial}{\partial p_J}) = \Omega(\frac{\partial}{\partial p_I}, - \frac{\partial}{\partial x_J}) = \delta_{IJ}, \hspace{1cm} (40)$$

so that Cond. 1 are satisfied. The saturation $\mathcal{C}^{sat}$ of $\mathcal{C}$ in $\mathcal{P}$ under the action of $\mathfrak{q}^n$, (35) and (38), is all of $\mathcal{P}$, and any $\mathfrak{q}^n$-orbit is of the form

$$\{(\vec{x}, \vec{p}) \in \mathbb{R}^{2m} : x_i, p_i fixed, i = n + 1, \ldots, m\}, \hspace{1cm} (41)$$
and therefore contains exactly one IR^m-orbit of the constraint surface C, demonstrating
the desired equivalence of the quotations

$$C^{sat}/\mathfrak{d}^n \cong C/IR^n.$$  \(\text{(42)}\)

Let us now slightly modify the definition of the complex structure on \(\mathcal{P}\) by defining

$$J' \frac{\partial}{\partial x_1} = \frac{\partial}{\partial p_1}, \quad J' \frac{\partial}{\partial x_m} = \frac{\partial}{\partial p_m}, \quad J' \frac{\partial}{\partial x_1} = - \frac{\partial}{\partial x_m}, \quad J' \frac{\partial}{\partial p_1} = - \frac{\partial}{\partial p_m},$$  \(\text{(43)}\)

and all other relations unchanged from (37). Proceeding as above leads to a complex action on IR^m with

$$\tau(i\xi^1) = i \frac{\partial}{\partial p_1}.$$  \(\text{(44)}\)

A IR^m-orbit on \(\mathcal{P}\) is now of the form

$$\{(\bar{x}, \bar{p}) \in IR^{2m} : p_1, x_m \text{ fixed}; x_a, p_a \text{ fixed}, a = n + 1, \ldots, m - 1\}.$$  \(\text{(45)}\)

Such an orbit does not intersect \(C\) unless \(p_1 = 0\), in which case it contains a whole one-parameter family (labelled by \(p_m\)) of IR^n-orbits in \(C\), which in turn are of the form

$$\{(\bar{x}, \bar{p}) \in IR^{2m} : p_i = 0, i = 1, \ldots, n; x_a, p_a \text{ fixed}, a = n + 1, \ldots, m\}.$$  \(\text{(46)}\)

However, this does not contradict our conjecture since the metric \(\gamma\) constructed according to (16) is not Riemannian; its signature is \((-,-,+,+).

### 4.2 Group of gauge transformations SO(n)

Let us now consider a typical non-abelian kinematic gauge theory, given by [21]

$$(Q, L_G, Q_{ph}) = (IR^n, L_{SO(n)}, IR^+)$$  \(\text{(47)}\)

where IR^+ = \(\{r \in IR, 0 < r < \infty\}\), \(L_{SO(n)}\) denotes the action of \(SO(n)\) in the fundamental representation,

$$x \in IR^n \mapsto L_Ax = Ax$$

$$A^t A = Id, \ det A = 1,$$  \(\text{(48)}\)

with \(Id\) denoting the \(n \times n\)-identity matrix. The action \(L_{SO(n)}\) is non-free for \(n > 2\) and the physical configuration space is the one-dimensional manifold IR^+ (after excluding the singular orbit \(\{0\}\)). The canonical lift of \(L_{SO(n)}\) to the phase space is

$$\tilde{L}_A : \mathcal{P} \to \mathcal{P}$$

$$\tilde{L}_A(x, p) = (Ax, Ap),$$  \(\text{(49)}\)

where \((x,p) \in \mathcal{P} = T^* IR^n = IR^n \times IR^n\).
The equivariant momentum map is, in accordance with (4),
\[ \mu(x, p)(T_{jk}) = pd x_i(T_{jk}^Q) = x T_{jk}^p, \quad 1 \leq j < k \leq n, \]
where
\[ T_{jk} \in so(n), \]
\[ (T_{jk})_{j'k'} = \delta_{jj'}\delta_{kk'} - \delta_{jk}\delta_{k'j'}, \]
\[ T_{jk}^Q = x_j \frac{\partial}{\partial x_k} - x_k \frac{\partial}{\partial x_j}. \]

The first-class constraints associated with (50) take the form
\[ x T_{jk}^p = 0, \quad 1 \leq j < k \leq n, \]
or, equivalently,
\[ x \wedge p = 0, \]
where the wedge in (52) denotes the exterior product of the two vectors \( x, p \in \mathbb{R}^n \) and we have identified \( so(n) \) with \( \Lambda^2 \mathbb{R}^n \). By exterior algebra arguments, (52) implies that the constraint surface \( \mathcal{C} \) is given by
\[ \mathcal{C} = \{ (x, p) \in \mathcal{P} : (x, p) = (\lambda f, \mu f), \lambda, \mu \in \mathbb{R}, f \in \mathbb{R}^n, \| f \|^2 = \sum_{i=1}^{n} f_i^2 = 1 \}. \]

To obtain the physical phase space, we must divide \( \mathcal{C} \) by the action of \( \tilde{L}_{SO(n)} \). Since the action of \( SO(n) \) is transitive on the unit sphere,
\[ S^{n-1} = \{ f \in \mathbb{R}^n, \| f \| = 1 \} \subset \mathbb{R}^n, \]
we have in each \( \tilde{L}_{SO(n)} \)-orbit a representative
\[ (\lambda f_1, \mu f_1) \in \mathcal{C}, \]
where \( f_1 = (1, 0, \ldots, 0) \). There is a residual gauge transformation
\[ (\lambda f_1, \mu f_1) \mapsto (-\lambda f_1, -\mu f_1), \]
which means that the physical phase space is a cone [21]:
\[ \mathcal{P}_{ph} = \mathcal{C}/\tilde{L}_{SO(n)} = \mathbb{R}^2 / \mathbb{Z}_2 = \{ [(\lambda, \mu)] : (\lambda, \mu) \in \mathbb{R}^2 \}, \]
where we denote the \( \mathbb{Z}_2 \)-equivalence classes by \( [(\lambda, \mu)] = \{ (\lambda, \mu), (-\lambda, -\mu) \} \). Alternatively, if we exclude the origin of \( \mathbb{R}^{2n}_+ \) and choose
\[ \mathcal{P} = \mathbb{R}^2_+ = \mathbb{R}^{2n}_+ \backslash \{0\}, \]
\(P_{ph}\) becomes a non-simply connected two-dimensional manifold,
\[
\mathcal{C}/L_{SO(n)} \equiv IR^2 = IR^2 \setminus \{0\}.
\]

Let us now see how this process of constraining and quotienting can be replaced by the single step of quotienting the big phase space (58) by the action of the complex group
\[
SO(n)_\mathfrak{q} = SO(n, \mathfrak{q}).
\]

Consider the complex kinematic gauge theory
\[
(Q^\mathfrak{q}, L_{Gq}, Q^\mathfrak{q}_{ph}) = (\mathfrak{q}^n, L_{SO(n, \mathfrak{q})}, \mathfrak{q}^m/L_{SO(n, \mathfrak{q})}),
\]

where \(L_{SO(n, \mathfrak{q})}\) denotes the standard (non-symplectic and, in fact, improper) action of \(SO(n, \mathfrak{q})\) on \(\mathfrak{q}^n\),

\[
L_A : \mathfrak{q}^n \rightarrow \mathfrak{q}^m \\
L_A z = A z, \quad z \in \mathfrak{q}^n,
\]

where \(z = x + ip\), \((x, p) \in IR^{2n}\) and \(A\) is a complex orthogonal \(n \times n\)-matrix with unit determinant. It is clear that the complex kinematic gauge theory (61) is a complexification of the theory (47) (see Def.1). Besides, the standard complex structure on \(\mathfrak{q}^n\) satisfies Cond.1 and, as we will show, the map (27) is a bijection. Let us demonstrate that \(\mathcal{C}^{sat}\) is dense in \(\mathcal{P} = \mathfrak{q}^n\), and that in order to give the set of orbits

\[
\mathcal{P}/L_{SO(n, \mathfrak{q})} = \mathfrak{q}^n/L_{SO(n, \mathfrak{q})}
\]

a differentiable structure, we must exclude the origin \(\{0\}\) and the orbits of \(L_{SO(n, \mathfrak{q})}\) which do not intersect \(\mathcal{C}\), that is

\[
\mathcal{P}_{ph} = \mathcal{C}/L_{SO(n)} = Q^\mathfrak{q}_{ph} = \mathcal{P}/L_{SO(n, \mathfrak{q})},
\]

where in this equality we have implicitly excluded non-typical orbits from \(\mathcal{P}/L_{SO(n, \mathfrak{q})}\). To show that \(\mathcal{C}^{sat}\) is dense in \(\mathcal{P} = \mathfrak{q}^n\), we consider the following sets in \(\mathfrak{q}^n\), which are invariant under \(L_{SO(n, \mathfrak{q})}\),

\[
D_w = \{z \in \mathfrak{q}^n \setminus \{0\} : z^2 = w\}.
\]

It can easily be shown that \(D_0\) does not intersect \(\mathcal{C}\) and that every \(D_w\) (for \(w \neq 0\)) contains a single orbit of \(L_{SO(m, \mathfrak{q})}\) and intersects \(\mathcal{C}\). Then

\[
\mathcal{C}^{sat} = \bigcup_{w \in \mathfrak{q}} D_w = \mathfrak{q}^m \setminus D_0,
\]

which proves that \(\mathcal{C}^{sat}\) is dense in \(\mathcal{P} = \mathfrak{q}^n\) since \(D_0\) has real codimension two. The orbits \(D_w\) are all of the type

\[
D_w \equiv SO(n, \mathfrak{q})/SO(n - 1, \mathfrak{q})
\]

while the orbits \(\{0\}\) and \(D_0\) are not. (It can be shown that \(D_0\) is just a single orbit, unless \(n = 2\), when it consists of two orbits.) Therefore, in order to give \(\mathcal{P}/L_{SO(n, \mathfrak{q})}\) a differentiable structure, we must exclude \(\{0\} \cup D_0\), which proves the validity of (64).
4.3 Grassmann manifolds as physical phase spaces of $U(m)$-gauge theories

Let us consider an example with a symplectic action of the group $U(m)$ in $\mathcal{P} = \mathbb{R}^{2mn} = T^*\mathbb{R}^{mn}$, which is not the lift of an action in the configuration space $\mathbb{R}^{mn}$ \footnote{We thank R. Picken for suggesting the $m = 1$ example.}. We take $\mathcal{P} = \mathbb{R}^{2mn} = \mathfrak{u}^{mn}$, endowed with the standard Kähler structure. The points in $\mathcal{P}$ can be considered either as complex $m \times n$-matrices,

$$z = (z_{ri})_{r=1}^m, i=1^n \in \mathcal{P},$$

or as sets of $m$ vectors in $\mathfrak{u}^n$ (the rows of $(z_{ri})$). Let the group $U(m)$ act by left multiplication,

$$L_A z = A z, \ A \in U(m),$$

and the group $SU(n)$ by right multiplication,

$$L_B z = zB, \ B \in SU(n).$$

Both actions leave the Kähler structure on $\mathcal{P} = \mathfrak{u}^{mn}$ invariant.

Let us assume that the group of gauge transformations is $U(m)$. The action of $U(m)$ is free for points $z \in \mathcal{P}$ such that rank$(z) = m$. Indeed, we have

$$L_A z = z \iff \sum_{s=1}^m (A_{rs} - \delta_{rs}) z_s = 0,$$

which, if rank$(z) = m$, implies that

$$A_{rs} = \delta_{rs}.$$ 

The action (69) has an equivariant momentum map, given by

$$\mu^{rs}(z) = \ e\delta_{rs} - \frac{1}{4} (z_r \bar{z}_s + \bar{z}_r z_s)$$

$$= \ e\delta_{rs} - \frac{1}{2} (p_r p_s + x_r x_s)$$

$$\mu^{rs}(z) = \frac{i}{4} (\bar{z}_r z_s - \bar{z}_s z_r)$$

$$= \frac{1}{2} (x_r p_s - x_s p_r),$$

where $u_r v_s \equiv \sum_{i=1}^n u_{ri} v_{si}$, and we have set $z_r = x_r + ip_r$. The generators $\xi_{rs}, \eta_{rs}$ form a basis in $\mathfrak{u}(m) \equiv \text{Lie}(U(m))$, given by

$$\xi_{rs} = \frac{i}{2} (E_{rs} + E_{sr})$$

$$\eta_{rs} = \frac{1}{2} (E_{rs} - E_{sr}),$$

\footnote{We thank R. Picken for suggesting the $m = 1$ example.}
where the $E_{rs}$ are the elementary $m \times m$-matrices

$$ (E_{rs})_{r's'} = \delta_{rr'} \delta_{ss'}. \quad (75) $$

One easily checks that the constant terms appearing on the right-hand side of (72) are the most general constants that on cohomological grounds can appear in the components of the momentum map. The first-class constraints associated with this action are

$$ \mu = 0 \iff \mu_{rs} = 0, \quad \mu_{rs} = 0, \quad \mu_{rs} = 0, \quad (76) $$

or, equivalently,

$$ z_r z_s = \delta_{rs}, \quad (77) $$

where we have set the constant to $c = 1/2$. We see that the elements of the constraint surface are sets of $m$ orthonormal vectors in $\mathfrak{g}^n$ with respect to the hermitian inner product

$$ <w, w'> = w \bar{w}' = \sum_{i=1}^{n} w_i \bar{w}_i'. $$

The action of $U(m)$ on $\mathcal{C}$ is free as explained above. Let $z^{(0)} \in \mathcal{C}$ and $\mathcal{L}$ be the subspace of $\mathfrak{g}^n$ spanned by $\{z_r^{(0)}\}_{r=1}^{m}$. Geometrically, by acting with $U(m)$ according to

$$ (Az^{(0)})_r = A_{rs} z_s^{(0)}, \quad (78) $$

we obtain all the orthonormal bases of $\mathcal{L} \subset \mathfrak{g}^n$. The points in the physical phase space $\mathcal{P}_{ph}$ are the orbits $[z]$ of $U(m)$ in $\mathcal{C}$. There is an obvious one-to-one map between $\mathcal{P}_{ph}$ and the complex Grassmann manifold $G_{m,n}(\mathfrak{g})$ of $m$-dimensional subspaces of $\mathfrak{g}^n$,

$$ \mathcal{P}_{ph} \rightarrow G_{m,n}(\mathfrak{g}) $$

$$ [z] \rightarrow \mathcal{L} = span\{z_s\}_{s=1}^{m} \quad (79) $$

That this map is a diffeomorphism follows from

**Proposition 3**  

- The constraint surface $\mathcal{C}$ is an orbit in $\mathcal{P}$ under the right action of the group $U(n)$.
- The isotropy group is $U(n-m)$ so that

$$ \mathcal{C}^{diff} \equiv U(n)/U(n-m). \quad (80) $$

- The physical phase space $\mathcal{C}/U(m)$ is therefore diffeomorphic to

$$ \mathcal{P}_{ph}^{diff} \equiv G_{m,n}(\mathfrak{g}) = U(n)/[U(n-m) \times U(m)]. \quad (81) $$
Let us now turn to the complexification of the symplectic action of $U(m)$ in order to study the form that our general result (that the map (27) is a diffeomorphism) takes in this particular example. The complexification of $U(m)$ is
\[ U(m)_\mathbb{C} = GL(m, \mathbb{C}). \] (82)

It is easy to verify that the action of $GL(m, \mathbb{C})$ on $\mathcal{P} = \mathfrak{d}^{\text{spin}}$ by left multiplication
\[ L_{A^\mathbb{C}} z = A^\mathbb{C} z, \quad A^\mathbb{C} \in GL(m, \mathbb{C}), \] (83)
is an extension of (69) in the sense of (12) and satisfies the conditions (15) and (16). Also, 0 is a regular value of the momentum map $\mu$ so that (27) is indeed a diffeomorphism. $\mathcal{C}^{\text{sat}}$ consists of all matrices $z \in \mathfrak{d}^{\text{spin}}$ with $\text{rank}(z) = m$. To prove this it is sufficient to notice that for any such matrix $z$ there is a matrix $A^\mathbb{C} \in GL(m, \mathbb{C})$ such that $A^\mathbb{C} z \in \mathcal{C}$ (e.g. by using the Graham-Schmidt orthogonalization procedure). Hence $\mathcal{C}^{\text{sat}}$ is dense in $\mathcal{P} = \mathfrak{d}^{\text{spin}}$, which is in accordance with our conjecture. Furthermore, the “bad” points outside $\mathcal{C}^{\text{sat}}$ are points with symmetries (i.e. with a non-trivial isotropy subgroup of $U(m)$).

The action of $GL(m, \mathbb{C})$ on $\mathcal{C}^{\text{sat}}$ is free by construction, and it is clear why the orbit space is diffeomorphic to the complex Grassmann manifold $G_{m,n}(\mathbb{C})$: the orbits are just the sets of all bases of a given $m$-dimensional subspace of $\mathfrak{d}^m$,
\[ \mathcal{P}_{\text{ph}} = G_{m,n}(\mathbb{C}) = \mathcal{C}/U(m) = \mathcal{C}^{\text{sat}}/GL(m, \mathbb{C}). \] (84)

5 Application to Yang-Mills theory

5.1 The hamiltonian formulation

In this section we review some geometric properties of the infinite-dimensional phase space of the Yang-Mills theory, which allow us to construct its complexification along the lines proposed Sec.3 above. We emphasize the geometric viewpoint of the theory, and refer the interested reader to references [2, 5, 19] for the analytic details.

Let $\Sigma$ be a compact, oriented manifold of dimension three, $P = P(\Sigma, K)$ a principal fibre bundle over $\Sigma$, with structure group $K$, a compact semisimple Lie group, and associated Lie algebra $\mathcal{K}$. The Killing form in $\mathcal{K}$ will be used to identify $\mathcal{K}$ with its dual $\mathcal{K}^\ast$.

The big configuration space of Yang-Mills theory is the affine space $\mathcal{A}$ of $\mathcal{K}$-valued connections on $P$. For simplicity, we assume $P$ to be trivial, so that we can identify $\mathcal{A}$ with the affine space of $\mathcal{K}$-valued one-forms (gauge potentials) on $\Sigma$. (Here and in the following all function spaces are assumed to belong to the appropriate Sobolev classes, see [19] for a discussion.) Then $\mathcal{A}$ is an affine space modelled on the vector
space $\mathfrak{T}^1(\Sigma; \mathcal{K})$ of $\mathcal{K}$-valued one-forms of adjoint type on $\Sigma$, and its tangent bundle can be identified with
\[ T\mathcal{A} \cong \mathcal{A} \times \mathfrak{T}^1(\Sigma; \mathcal{K}). \]  
Equation (85)
The corresponding Yang-Mills phase space will be identified with the $(L^2)$ cotangent bundle
\[ T^*\mathcal{A} \cong \mathcal{A} \times \mathfrak{X}_d(\Sigma; \mathcal{K}), \]  
Equation (86)
where $\mathfrak{X}_d(\Sigma; \mathcal{K})$ denotes the space of $\mathcal{K}$-valued vector densities (or non-abelian electric fields) on $\Sigma$. At any point $\mathcal{A} \in \mathcal{A}$, the dual pairing between $T_{\mathcal{A}}^* \mathcal{A} \cong \mathfrak{X}_d(\Sigma; \mathcal{K})$ and $T_{\mathcal{A}} \mathcal{A} \cong \mathfrak{T}^1(\Sigma; \mathcal{K})$ is given by
\[ (\alpha, \dot{\mathcal{E}}) = \int_{\Sigma} \alpha : \dot{\mathcal{E}}, \]  
Equation (87)
where $\alpha \in T_{\mathcal{A}} \mathcal{A}$, $\dot{\mathcal{E}} \in T_{\mathcal{A}}^* \mathcal{A}$, and $":\$ denotes the complete contraction of internal and spatial indices (internal indices are contracted with the Killing form on $\mathcal{K}$).

The gauge group $G$ of Yang-Mills theory is the group of $\mathcal{K}$-valued functions $g : \Sigma \to K$, on $\Sigma$, and its Lie algebra $\mathfrak{g}$ is given by the Lie algebra of $\mathcal{K}$-valued functions $\xi : \Sigma \to \mathcal{K}$, on $\Sigma$. The dual of $\mathfrak{g} \cong \Lambda^0(\Sigma; \mathcal{K})$ is the space $\mathfrak{g}^* \cong \Lambda^0(\Sigma; \mathcal{K})$ of $\mathcal{K}$-valued scalar densities on $\Sigma$. The dual pairing between an algebra element $\xi \in \mathfrak{g}$ and a scalar density $\eta \in \mathfrak{g}^*$ is given by
\[ \langle \xi, \dot{\eta} \rangle = \int_{\Sigma} \xi : \dot{\eta}. \]  
Equation (88)
The group $G$ acts on the configuration space $\mathcal{A}$ according to the affine map
\[ (g, A) \mapsto \varphi_g(A) = g^{-1}Ag + g^{-1}dg, \]  
Equation (89)
whose canonical lift to the phase space $T^*\mathcal{A}$ yields the well-known Yang-Mills transformation law
\[ (g, (A, \dot{\mathcal{E}})) \mapsto \tilde{\varphi}_g(A, \dot{\mathcal{E}}) = (g^{-1}Ag + g^{-1}dg, g^{-1}\dot{\mathcal{E}}g). \]  
Equation (90)
The action (90) is symplectic with respect to the canonical (constant) symplectic form $\Omega$ on $T^*\mathcal{A}$,
\[ \Omega_{(A, \dot{\mathcal{E}})}((\delta A_1, \delta \dot{\mathcal{E}}_1), (\delta A_2, \delta \dot{\mathcal{E}}_2)) = (\delta A_1, \delta \dot{\mathcal{E}}_2) - (\delta A_2, \delta \dot{\mathcal{E}}_1), \]  
Equation (91)
for tangent vectors $(\delta A_i, \delta \dot{\mathcal{E}}_i) \in T_{(A, \dot{\mathcal{E}})}(T^*\mathcal{A})$, where $(\cdot, \cdot)$ denotes the duality (87). Note that in this last equation we have used the identification
\[ T_{(A, \dot{\mathcal{E}})}(T^*\mathcal{A}) \cong \mathfrak{T}^1(\Sigma; \mathcal{K}) \times \mathfrak{X}_d(\Sigma; \mathcal{K}). \]  
Equation (92)
The infinitesimal generator of the configuration space action (89) associated to the algebra element $\xi \in \mathfrak{g}$ is the vector field $\xi^A \in \mathfrak{X}\mathcal{A}$, given by
\[ \xi^A(A) = (A, D_A\xi) = (D_A\xi) \frac{\delta}{\delta A}, \]  
Equation (93)
where $D_A = d \cdot [A \wedge \cdot]$ is the covariant derivative defined by the connection $A$. 

17
