Abstract

We study a massless scalar field propagating in the background of a five-dimensional rotating black hole. We showed that in the Myers-Perry metric describing such a black hole the massless field equation allows the separation of variables. The obtained angular equation is a generalization of the equation for spheroidal functions. The radial equation is similar to the radial Teukolsky equation for the 4-dimensional Kerr metric. We use these results to quantize the massless scalar field in the space-time of the 5-dimensional rotating black hole and to derive expressions for energy and angular momentum fluxes from such a black hole.

1 Introduction

Solutions of Einstein’s equations describing black holes in space-times with more than usual (3 + 1)-dimensions have been known in literature for forty years \cite{1}. Until recently, they were practically only of academic interest. The situation has changed with appearance of so-called brane world models \cite{2} in which large extra spatial dimensions can exists (much larger than the apparent Planck length scale $\sim 10^{-33}$ cm). In this framework, the fundamental quantum gravity energy scale could be in 1TeV range, while the characteristic length scale (compactification radius of extra dimensions) can be as large as 0.1mm.
This allows existence of higher dimensional mini-black holes which can be described within the classical theory of gravity. Being gravitational solitons black holes in the brane world can ‘live’ out of the brane in the bulk space. If the gravitational radius of such a black hole is much smaller than the distance to the brane and the characteristic length defined by the bulk curvature and/or the size of extra dimensions, the influence of the external conditions on the properties of the space-time near the horizon is small. Under these conditions in order to describe the black hole one can use solutions of vacuum Einstein equations. This also can be true for small black holes attached to the brane provided the brane is “soft”, that is its tension is small.

From phenomenological point of view, the most exciting possibility is that such mini-black holes can be produced in particle collisions in near future accelerator and cosmic ray experiments [3]. In order to predict the correct experimental signature of these events, one has to know the basic properties of solutions of these higher dimensional black holes. In general case, the impact parameter in particle collision will be non-zero. Therefore, majority of black holes produced in such way would be rotating.

The metric for higher dimensional rotating black holes was derived by Myers and Perry [4]. In the present paper, we study the massless scalar field equation in a five-dimensional rotating black hole described by the Myers-Perry metric. We show that this equation allows the separation of variables. The obtained angular equation is a generalization of the equation for spheroidal functions. The radial equation is similar to the radial Teukolsky equation for the 4-dimensional Kerr metric.

In the case of $3+1$ dimensions, there is only one parameter of rotation and there is an axis of rotation which stays invariant under rotation. The rotation group in $4+1$ dimensions, $SO(4)$, has two Casimir operators. Rather than an axis of rotation, there exist planes of rotation which stay invariant under the rotation. This implies that, in general, there are two parameters of rotation corresponding to two independent planes of rotation. In a special case, one can set one of the parameters to zero and consider rotations only in one plane. We find interesting that in another special case, when both parameters of rotation are non-zero and equal in magnitude, the angular equation reduces to a case of a non-rotating black hole. For this special case the space-time has two additional Killing vectors. It is interesting that the spatial 3-dimensional slices of this spacetime are homogeneous and belong to the Bianchi type VIII class.

We analyze the structure and asymptotics of solutions of the radial equation which determine the black hole gray-body factors. We use these results to quantize the massless scalar field in the spacetime of the 5-dimensional rotating black hole and to derive expressions for energy and angular momentum fluxes from such a black hole.

### 2 Myers-Perry Metric

#### 2.1 Generic case

Following Myers and Perry [4] we write the metric of a 5-dimensional rotating black hole in the form

$$ds^2 = -dt^2 + (r^2 + a_1^2)(d\mu_1^2 + \mu_1^2 \, d\phi_1^2) + (r^2 + a_2^2)(d\mu_2^2 + \mu_2^2 \, d\phi_2^2)$$
\[ + \frac{\Pi \mathcal{F}}{\Pi - r_0^2 r^2} \, dr^2 + \frac{r_0^2 r^2}{\Pi \mathcal{F}} \left( dt + a_1 \mu_1^2 d\phi_1 + a_2 \mu_2^2 d\phi_2 \right)^2, \quad (2.1) \]

\[ \mathcal{F} = 1 - \frac{a_1^2 \mu_1^2}{r^2 + a_1^2} - \frac{a_2^2 \mu_2^2}{r^2 + a_2^2}, \quad (2.2) \]

\[ \Pi = (r^2 + a_1^2)(r^2 + a_2^2). \quad (2.3) \]

Here \( r_0 \) is length parameter connected with the black hole mass \( M \)

\[ M = \frac{3r_0^2}{8\sqrt{\pi}G}. \quad (2.4) \]

where \( G \) is the \((4 + 1)\)-dimensional gravitational coupling constant. Besides \( r_0 \) the metric (2.1) contains two rotation parameters, \( a_1 \) and \( a_2 \). The variables \( \mu_1 \) and \( \mu_2 \) are not independent. They obey a constraint

\[ \mu_1^2 + \mu_2^2 = 1. \quad (2.5) \]

Instead of keeping the symmetric form of the metric (2.1) we prefer to solve the constraint (2.5) explicitly. We use the following parametrization

\[ \mu_1 = \sin \theta, \quad \mu_2 = \cos \theta. \quad (2.6) \]

Let us also introduce the following notations

\[ a = a_1, \quad b = a_2, \quad \phi = \phi_1, \quad \psi = \phi_2, \quad (2.7) \]

\[ \rho^2 = r^2 + a^2 \cos^2 \theta + b^2 \sin^2 \theta, \quad (2.8) \]

\[ \Delta = (r^2 + a^2)(r^2 + b^2) - r_0^2 r^2. \quad (2.9) \]

Then the metric (2.1) takes the form

\[ ds^2 = d\gamma^2 + \frac{r^2 \rho^2}{\Delta} \, dr^2 + \rho^2 \, d\theta^2. \quad (2.10) \]

\[ d\gamma^2 \equiv \gamma_{AB} \, dx^A \, dx^B = -dt^2 + (r^2 + a^2) \sin^2 \theta \, d\phi^2 + (r^2 + b^2) \cos^2 \theta \, d\psi^2 \\
+ \frac{r_0^2}{\rho^2} \left[ dt + a \sin^2 \theta \, d\phi + b \cos^2 \theta \, d\psi \right]^2. \quad (2.11) \]

Here \( A, B = 0, 3, 4 \) and \( x^0 = t, \ x^3 = \phi, \ x^4 = \psi \). Angles \( \phi \) and \( \psi \) take values from the interval \([0, 2\pi]\), while angle \( \theta \) takes values \([0, \pi/2]\).

The metric (2.10) is invariant under the following transformation

\[ a \leftrightarrow b, \quad \theta \leftrightarrow \frac{\pi}{2} - \theta, \quad \phi \leftrightarrow \psi. \quad (2.12) \]

It possesses 3 Killing vectors, \( \partial_t, \partial_\phi \) and \( \partial_\psi \). For this metric

\[ \sqrt{-g} = \sin \theta \cos \theta \, r \, \rho^2. \quad (2.13) \]
The black hole horizon is located at \( r = r_+ \) where

\[
    r_\pm = \frac{1}{2} \left[ r_0^2 - a^2 - b^2 \pm \sqrt{(r_0^2 - a^2 - b^2)^2 - 4a^2b^2} \right].
\]  

(2.14)

The angular velocities \( \Omega_a \) and \( \Omega_b \) and the surface gravity \( \kappa \) are

\[
    \Omega_a = \frac{a}{r_+^2 + a^2}, \quad \Omega_b = \frac{b}{r_+^2 + b^2}
\]

(2.15)

\[
    \kappa = \frac{\partial_r \Pi - 2r_0^2 r}{2r_0^2 r^2} \bigg|_{r=r_+}.
\]

(2.16)

2.2 Degenerate case

As we already mentioned in a general case the Myers-Perry metric has 3 Killing vectors. The space-time becomes more symmetric when \( a = b \). To demonstrate this let us consider first the geometry of the section \( t = \text{const} \). It has the form

\[
    ds_4^2 = \frac{r^2 (r^2 + a^2)}{(r^2 + a^2)^2 - r_0^2 r^2} dr^2 + ds_3^2,
\]

(2.17)

\[
    ds_3^2 = \alpha \left( d\theta^2 + \sin^2 \theta d\phi^2 + \cos^2 \theta d\psi^2 \right) + \beta \left( \sin^2 \theta d\phi + \cos^2 \theta d\psi \right)^2,
\]

(2.18)

where

\[
    \alpha = r^2 + a^2, \quad \beta = \frac{r_0^2 a^2}{r^2 + a^2}.
\]

(2.19)

By introducing new coordinates

\[
    \Phi = \psi - \phi, \quad \Psi = \psi + \phi, \quad \vartheta = 2\theta,
\]

(2.20)

where \( \Psi \) takes values from the interval \([0, 4\pi]\), \( \Phi \) from \([-2\pi, 2\pi]\) and \( \vartheta \) from \([0, \pi]\), one can rewrite the metric (2.18) as follows

\[
    ds_3^2 = A \left( d\vartheta^2 + \sin^2 \vartheta d\Phi^2 \right) + B \left( \cos \vartheta d\Phi + d\Psi \right)^2.
\]

(2.21)

Here,

\[
    A = \frac{\alpha}{4}, \quad B = \frac{\alpha + \beta}{4}.
\]

(2.22)

This is a canonical form of the Bianchi VIII type metric when there exists a four-parameter group of isometries acting transitively in the 3-dimensional space [5]. The corresponding Killing vectors are

\[
    K_1 = \partial_\Phi, \quad K_2 = \partial_\Psi,
\]

\[
    K_3 = \cos \Phi \partial_\vartheta - \cot \vartheta \sin \Phi \partial_\Phi + \frac{\sin \Phi}{\sin \vartheta} \partial_\Psi,
\]

(2.23)

\[
    K_4 = -\sin \Phi \partial_\vartheta - \cot \vartheta \cos \Phi \partial_\Phi + \frac{\cos \Phi}{\sin \vartheta} \partial_\Psi.
\]
It is easy to check that these vectors (together with \( \partial_t \)) are also Killing vectors for the 5-dimensional space-time metric (2.10) when \( a = b \).

Killing vectors can be viewed as generators of the symmetry group of the manifold. We can obtain a more familiar form of these Killing vectors. First note that:

\[
K_3 K_4 - K_4 K_3 = K_1
\]  
(2.24)

where multiplications denote successive applications of an operator. Then, the quadratic combination \( K_3^2 + K_4^2 + K_1^2 \) yields

\[
K_3^2 + K_4^2 + K_1^2 = \frac{\partial^2}{\partial \vartheta^2} + \cot \vartheta \frac{\partial}{\partial \vartheta} + \frac{1}{\sin^2 \vartheta} \left( \frac{\partial^2}{\partial \Phi^2} - 2 \cos \vartheta \frac{\partial}{\partial \Phi} \frac{\partial}{\partial \Psi} + \frac{\partial^2}{\partial \Psi^2} \right)
\]  
(2.25)

We can identify

\[
J_\Phi \equiv -iK_1, \quad J_\Psi \equiv -iK_2, \quad J^2 \equiv -(K_3^2 + K_4^2 + K_1^2),
\]  
(2.26)

where \( J_\Phi, J_\Psi \) and \( J^2 \) are familiar angular momentum operators, while \( \Phi, \Psi \) and \( \vartheta \) are Euler angles for the rotation group \( O(3) \).

The scalar curvature \( R \) for the metric (2.18)

\[
R = 2 \frac{3(r^2 + a^2)^2 - a^2 r_0^2}{(r^2 + a^2)^3}
\]  
(2.27)

is constant at fixed \( r \) and has a positive sign as long as \( r > a \sqrt{\frac{r_0^2}{3} - \frac{1}{a}} \).

Another interesting observation is the following. Instead of metric on slices \( t = \text{const} \), one can consider the 4-dimensional foliation of the space-time by the Killing trajectories of the field \( \xi_t = \partial_t \). The metric on this foliations is determined as [6]

\[
g^{(4)}_{\mu\nu} = g_{\mu\nu} - \frac{\xi_\mu \xi_\nu}{\xi^2}.
\]  
(2.28)

For the Myers-Perry metric (2.1) this metric is

\[
dS^2 \equiv g^{(4)}_{\mu\nu} dx^\mu dx^\nu = \frac{r^2 (r^2 + a^2)}{(r^2 + a^2)^2 - r_0^2 r^2} dr^2 + dS_3^2,
\]  
(2.29)

where \( dS_3^2 \) has the form (2.18) with

\[
\alpha = r^2 + a^2, \quad \beta = \frac{r_0^2 a^2}{r^2 + a^2 - r_0^2}.
\]  
(2.30)

Thus this metric is also a metric of homogeneous 3-dimensional space with the 4-parameter group of motion.

The scalar curvature for the metric \( dS_3^2 \)

\[
R = 2 \frac{3(r^2 + a^2)^2 - 3r_0^2 r^2 - 4r_0^2 a^2}{(r^2 + a^2)^2 (r^2 + a^2 - r_0^2)}
\]  
(2.31)

is also constant for \( r = \text{const} \) and it is positive for:

\[
r > \frac{1}{6} \sqrt{18r_0^2 - 36a^2 + 6 \sqrt{9r_0^4 + 12r_0^2 a^2}}.
\]  
(2.32)
2.3 Flat space-time limit

When \( r_0 = 0 \) the metric takes the form

\[
\begin{align*}
    ds^2 &= -dt^2 + (r^2 + a^2) \sin^2 \theta \, d\phi^2 + (r^2 + b^2) \cos^2 \theta \, d\psi^2 + \frac{r^2 \rho^2 \, dr^2}{(r^2 + a^2)(r^2 + b^2)} + \rho^2 \, d\theta^2. \\
\end{align*}
\]

(2.33)

Such a space-time is flat and the metric can be rewritten as

\[
    ds^2 = -dT^2 + dX^2 + dY^2 + dZ^2 + dW^2 = -dT^2 + dR^2 + R^2 \, d\Omega_3^2,
\]

(2.34)

where \( T = t \) and

\[
    X = \sqrt{r^2 + a^2} \sin \theta \cos \phi, \quad Y = \sqrt{r^2 + a^2} \sin \theta \sin \phi,
\]

\[
    Z = \sqrt{r^2 + b^2} \cos \theta \sin \psi, \quad W = \sqrt{r^2 + b^2} \cos \theta \sin \psi.
\]

(2.35)

Here

\[
    \tilde{\phi} = \phi - \tan^{-1}(a/r), \quad \tilde{\psi} = \psi - \tan^{-1}(b/r).
\]

(2.36)

and \( d\Omega_3^2 \) is the line element on a unit 3-sphere \( S^3 \). At far distances \( R \) and \( r \) differs only by terms of the order of \( a^2/r \) and \( b^2/r \). Also normals to \( R = \text{const} \) and \( r = \text{const} \) coincide with the same accuracy.

A two-dimensional plane \( Z = W = 0 \) (\( X - Y \)-plane \( \Pi_{XY} \)) is a plane of rotation, while \( \Pi_{ZW} \) where \( X = Y = 0 \) is a two-plane orthogonal to \( \Pi_{XY} \).

3 Scalar field equation. Separation of variables

Let us consider a scalar massless field \( \varphi \) with the action

\[
    W[\varphi] = -\frac{1}{2} \int d^5 x \, \sqrt{-g} \left( (\nabla \varphi)^2 + \xi R \varphi^2 \right).
\]

(3.1)

It obeys the following equation

\[
    \square \varphi - \xi R \varphi = \frac{1}{\sqrt{-g}} \partial_{\mu} \left( \sqrt{-g} g^{\mu \nu} \partial_{\nu} \varphi \right) - \xi R \varphi = 0.
\]

(3.2)

The space-time (2.10) is Ricci flat so that \( R = 0 \). Let us denote \( \Box^* = \rho^2 \Box \). Then the field equation

\[
    \Box^* \varphi = 0
\]

(3.3)

can be identically written in the form

\[
    H_{AB}^{\varphi,AB} + \frac{1}{r} \partial_r \left[ \frac{\Delta}{r} \partial_r \varphi \right] + \frac{1}{\sin \theta \cos \theta} \partial_\theta \left[ \sin \theta \cos \theta \partial_\theta \varphi \right] = 0,
\]

(3.4)

where \( H_{AB}^{\varphi} = \rho^2 g_{AB}^{\varphi} \). We used GRTensor program to calculate \( g^{\mu \nu} \) and \( \sqrt{-g} \). The components of \( H_{AB}^{\varphi} \) are

\[
    H^{rt} = (a^2 - b^2) \sin^2 \theta - \frac{(r^2 + a^2)[\Delta + r_0^2(r^2 + b^2)]}{\Delta},
\]

(3.5)
\[ H^{\phi\phi} = \frac{1}{\sin^2 \theta} - \frac{(a^2 - b^2)(r^2 + b^2) + b^2 r_0^2}{\Delta}, \quad (3.6) \]
\[ H^{\psi\psi} = \frac{1}{\cos^2 \theta} + \frac{(a^2 - b^2)(r^2 + a^2) - a^2 r_0^2}{\Delta}, \quad (3.7) \]
\[ H^{t\phi} = \frac{a r_0^2 (r^2 + b^2)}{\Delta}, \quad H^{t\psi} = \frac{b r_0^2 (r^2 + a^2)}{\Delta}, \quad H^{\phi\psi} = -\frac{ab r_0^2}{\Delta}. \quad (3.8) \]

The equation (3.4) allows the separation of variables. Namely its solution can be decomposed into modes of the form
\[ \varphi \sim e^{-i\omega t} e^{i m \phi} e^{i k \psi} R(r) \Theta(\theta). \quad (3.9) \]

The angular function \( \Theta \) obeys the equation
\[ \frac{d}{d\theta} \left( \sin \theta \cos \theta \frac{d\Theta}{d\theta} \right) + \left[ \lambda - \omega^2 (a^2 \sin^2 \theta + b^2 \cos^2 \theta) - \frac{m^2}{\sin^2 \theta} - \frac{k^2}{\cos^2 \theta} \right] \sin \theta \cos \theta \Theta = 0. \quad (3.10) \]

The radial equation reads
\[ \Delta \frac{d}{dr} \left[ \frac{\Delta dR}{r \frac{d}{dr}} \right] + W R = 0, \quad (3.11) \]
\[ W = \Delta \left( -\lambda + \omega^2(r^2 + a^2 + b^2) + \frac{m^2(a^2 - b^2)}{r^2 + a^2} + \frac{k^2(b^2 - a^2)}{r^2 + b^2} \right) + \frac{r_0^2(r^2 + a^2)(r^2 + b^2)}{w - \frac{ma}{r^2 + a^2} - \frac{kb}{r^2 + b^2}} \right). \quad (3.12) \]

We used the freedom \( \lambda \to \lambda + \text{const} \) in the choice of the separation constant \( \lambda \) in order to get the angular and radial equations in the most symmetric way. For this choice these equations are invariant under the transformation
\[ a \leftrightarrow b, \quad \theta \leftrightarrow \frac{\pi}{2} - \theta, \quad m \leftrightarrow k. \quad (3.13) \]

It should be emphasized that the separability of the field equation (3.3) is directly connected with the existence of the Killing tensor for the metric (2.10)–(2.11). The explicit form of this Killing tensor and discussion of its properties can be found in [7].

### 4 Hyperspheroidal functions

#### 4.1 Generic case

The angular equation can be rewritten for \( S(\theta) = \sqrt{\cos \theta} \Theta(\theta) \) as follows
\[ \frac{d^2 S}{d\theta^2} + \frac{\cos \theta}{\sin \theta} \frac{dS}{d\theta} + U_\lambda S = 0, \quad (4.1) \]
\[ U_\lambda = \tilde{\lambda} - \alpha \sin^2 \theta - \frac{m^2}{\sin^2 \theta} - \frac{k^2 - 1/4}{\cos^2 \theta} \quad (4.2) \]
where $\alpha = (a^2 - b^2)\omega^2$ and $\tilde{\lambda} = \lambda - \omega^2 b^2 + \frac{3}{4}$.

We discuss now properties of solutions of this equation. We are looking for solutions which are regular at singular points of the equation, $\theta = 0$ and $\theta = \pi/2$. This condition singles out special discrete values of $\lambda$ which we enumerate by an integer number $\ell$. Finding eigenvalues $\lambda_{\ell}(m, k|\alpha)$ and eigenfunctions $S_{\ell,m,k}^{\theta}(\theta|\alpha)$ is a well defined problem. Standard arguments show that the eigenfunctions with different $\lambda_{\ell}(m, k|\alpha)$ are orthogonal one to another with the proper chosen measure. Thus we write

$$
\int_0^{\pi/2} d\theta \sin \theta S_{\ell,m,k}^{\theta}(\theta|\alpha) S_{\ell',m,k}^{\theta}(\theta|\alpha) = \delta_{\ell,\ell'}.
$$

In what follows we shall use the following normalized set of functions

$$
Y_{\ell mk}(\theta, \phi, \psi|\alpha) = e^{im\phi + ik\psi} S_{\ell,m,k}^{\theta}(\theta|\alpha) \sqrt{\cos \theta}.
$$

We shall also use the compact notation for the index, $A = \{\ell, m, k\}$. This set of functions possess the following normalization conditions

$$
\int d\gamma Y_A \bar{Y}_{A'} = \delta_{AA'},
$$

where

$$
\int d\gamma(\ldots) = \int_0^{\pi/2} \sin \theta \cos \theta d\theta \int_0^{2\pi} d\phi \int_0^{2\pi} d\psi (\ldots), \quad \delta_{AA'} = \delta_{\ell\ell'} \delta_{mm'} \delta_{kk'}.
$$

With $x = \cos(\theta)$, the equation (4.1) can be rewritten as follows

$$
\frac{d}{dx} \left[(1 - x^2) \frac{dS}{dx}\right] + U_{\lambda} S = 0,
$$

$$
U_{\lambda} = \tilde{\lambda} + \alpha x^2 - \frac{m^2}{1 - x^2} - \frac{k^2 - 1/4}{x^2}.
$$

This equation besides $\infty$ has three singular points $x = 0, \pm 1$ at which solutions have the following asymptotic behavior

$$
S(x) \sim x^{\pm k}, \ \text{at} \ x = 0, \quad S(x) \sim (1 \mp x)^{\pm m/2}, \ \text{at} \ x = \pm 1.
$$

For a regular solution we have

$$
S(x) = x^{|k|} (1 - x^2)^{|m|/2} F(x),
$$

where $F$ is a solution of the equation

$$
x^2(1 - x^2) F'' + (-2 x^3 |m| - 2 x^3 |k| + 2 x |k| - 2 x^3) F' + \left(a^2 \omega^2 x^4 + [\lambda - (|m| + |k|)^2 - (|m| + |k|)] x^2 + \frac{1}{4} - |k|\right) F = 0.
$$

The regularity condition means that we are looking for a solutions $F(x)$ which are finite at $x = 0$ and at $x = 1$. This gives us the two-point boundary value problem.
4.2 Degenerate case

Consider now the degenerate case when \( a = b \). A solution \( S \) of (4.1) is of the form

\[
S^{[m],[k]}(\theta) = \sin^{[m]} \theta \sqrt{\cos \theta} \left[ C_1 \cos^{[k]} \theta S^{[m],[k]}(|k|, \theta) + C_2 \cos^{-[k]} \theta S^{[m],[k]}(-|k|, \theta) \right],
\]

(4.12)

\[
s^{[m],[k]}(|k|, \theta) = F(\alpha_+, \alpha_-; 1 + |k|; \cos^2 \theta).
\]

(4.13)

\[
\alpha_\pm = \frac{|m| + 1 + |k|}{2} \pm \frac{1}{2} \sqrt{1 + \lambda} \pm \frac{1}{2} \sqrt{1 + \lambda}.
\]

(4.14)

Here \( F(a, b; c; z) \) is a hypergeometric function. The coefficients of this function in our case possess the property \( a + b - c = |m| = \text{(positive) integer number} \). The regularity of \( S \) at \( \theta = \pi/2 \) requires \( C_2 = 0 \), while its regularity at \( \theta = 0 \) implies

\[
\frac{|m| + 1 + |k|}{2} - \frac{1}{2} \sqrt{1 + \lambda} = -\ell,
\]

(4.15)

where \( \ell \) is an integer number. Thus we have

\[
\lambda_\ell(|m|, |k|) = (2\ell + |m| + |k| + 1)^2 - 1.
\]

(4.16)

The corresponding eigenfunctions are the Jacobi polynomials \( P^{[m],[k]}(1 - 2 \cos^2 \theta) \). Thus

\[
\mathcal{Y}_mk(\theta, \phi, \psi|\alpha = 0) = e^{im\phi + ik\psi} \frac{1}{2\pi} (1 - z)^{|m|/2}(1 + z)^{|k|/2}B^{[m],[k]}|\ell^{[m],[k]}(z).
\]

(4.17)

where \( z = \cos(2\theta) = \cos \vartheta \) and

\[
B^{[m],[k]}|\ell^{[m],[k]} = 2^{-\frac{|m|+|k|+1}{2}} \sqrt{2\ell + |m| + |k| + 1} \frac{\Gamma(\ell + 1)\Gamma(\ell + |m| + |k| + 1)}{\Gamma(\ell + |m| + 1)\Gamma(\ell + |k| + 1)}.
\]

(4.18)

Note that for \( a = b \) the hyperspheroidal harmonics (4.4) are eigen functions of the operators \( J \Phi, J \Psi \), and \( J^2 \) determined by (2.26). Using this fact one can demonstrate that the set (4.4) of hyperspheroidal harmonics is complete (see e.g. \([8, 9]\)). For this set we have \( m = 0, \pm 1, \pm 2 \ldots, k = 0, \pm 1, \pm 2 \ldots, l = 0, 1, 2 \ldots \).

5 Radial equation

It is convenient to rewrite the radial equation (3.11) as follows. Let’s define

\[
R = \left[ \frac{r}{(r^2 + a^2)(r^2 + b^2)} \right]^{1/2} \mathcal{R}.
\]

(5.1)

Then, one has

\[
\frac{d^2 \mathcal{R}}{dr^2} + V \mathcal{R} = 0,
\]

(5.2)
where \( r_* \) is a tortoise coordinate with the property
\[
\frac{dr_*}{dr} = \frac{(r^2 + a^2)(r^2 + b^2)}{\Delta}.
\] (5.3)

The effective potential \( V \) is:
\[
V = \frac{r^2\Delta}{(r^2 + a^2)(r^2 + b^2)} \left[ -\lambda + \omega^2 (r^2 + a^2 + b^2) + \frac{m^2(a^2-b^2)}{r^2+a^2} + \frac{k^2(b^2-a^2)}{r^2+b^2} \right] + \frac{Z\Delta^2}{4r^2(r^2 + a^2)^2(r^2 + b^2)^2}
\]
\[
+ \frac{r_0^2r^2 \left( \omega - \frac{ma}{r^2+a^2} - \frac{kb}{r^2+b^2} \right)^2}{(r^2 + a^2)(r^2 + b^2)}
\] (5.4)

where
\[
Z = 21r^8 + 14r^6(a^2 + b^2) + 5r^4(a^2 - b^2)^2 - 10r^2a^2b^2(a^2 + b^2) - 3a^4b^4.
\]

The radial equation is evidently invariant under the transformation
\[
a \leftrightarrow b \quad m \leftrightarrow k.
\] (5.5)

At the horizon, i.e. \( r = r_+ \), the effective potential \( V \) takes the form
\[
V_{\text{hor}} = (\omega - m\Omega_a - k\Omega_b)^2,
\] (5.6)

with \( \Omega_a \) and \( \Omega_b \) defined by the eq. (2.15). The asymptotic value of the potential \( V \) at infinity is
\[
V_{\text{inf}} = \omega^2.
\] (5.7)

We define two sets of solutions \( R^\text{in}_A(r|\omega) \) and \( R^\text{up}_A(r|\omega) \) (with \( A = \{ \ell, m, k \} \)) by the boundary conditions
\[
R^\text{in}_A(r|\omega) \sim \begin{cases} 
  t^\text{in}_A(\omega) e^{-i\varpi r_*} & \text{as } r \to r_+,
  \\
  e^{-i\varpi r_*} + r^\text{in}_A(\omega) e^{i\varpi r_*} & \text{as } r \to \infty,
\end{cases}
\] (5.8)

and
\[
R^\text{up}_A(r|\omega) \sim \begin{cases} 
  t^\text{up}_A(\omega) e^{-i\varpi r_*} + e^{i\varpi r_*} & \text{as } r \to r_+,
  \\
  t^\text{up}_A(\omega) e^{i\varpi r_*} & \text{as } r \to \infty.
\end{cases}
\] (5.9)

Here
\[
\varpi = \omega - m\Omega_a - k\Omega_b.
\] (5.10)

Since the eigenvalues \( \lambda_\ell(mk|\alpha) \) are real the functions complex conjugated to \( R^\text{up}_J \) and \( R^\text{up}_J \) are also solutions. Using the constancy of the Wronskian for various combinations of solutions of the radial equation one gets
\[
1 - |r^\text{in}_A(\omega)|^2 = \frac{\varpi}{\omega} |t^\text{in}_A(\omega)|^2, \quad 1 - |r^\text{up}_A(\omega)|^2 = \frac{\omega}{\varpi} |t^\text{up}_A(\omega)|^2,
\] (5.11)
\[ \omega \tilde{r}_A^{\up}(\omega) r_j^{\in}(\omega) = -\omega \tilde{r}_A^{\up}(\omega) t_j^{\in}(\omega), \quad \omega t_A^{\up}(\omega) = \varpi t_A^{\in}(\omega). \]  

(5.12)

It should be emphasized that, as it was the case in 3 + 1 dimensions, for certain values of \( \omega \) it is possible to have the reflection coefficients greater than one. This implies the existence of the so-called superradiance effect. The condition for superradiance is

\[ 0 < \omega < m\Omega_a + k\Omega_b. \]  

(5.13)

In this case, it follows from (5.11) that the reflection coefficients \( r_A^{\in,\up}(\omega) \) become greater than one. This is the consequence of the fact that the scalar field modes obeying (5.13) are amplified by the rotating black hole.

6 Energy and angular momentum fluxes

Quantization of massless fields in the 4-dimensional space-time of a rotating black hole was discussed in [10, 11, 12, 13] (see also [14]). Main aspects of the quantization including the choice of the state remain practically the same in the 5-dimensional case. For this reason we shall not repeat here all the formal elements of the standard procedure but simply introduce the required notations and present the final results. We shall follow the paper [13] where necessary details can be found.

In order to quantize the field one uses the complete set of orthonormal complex solutions of the field equation (3.2). The scalar product for these solutions is defined as follows

\[ \langle \varphi_1, \varphi_2 \rangle = \frac{i}{2} \int_{\Sigma} \sqrt{-g} (\tilde{u}_2,\mu u_1 - \tilde{u}_1,\mu u_2) d\Sigma^\mu, \]  

(6.1)

where \( \Sigma \) is any complete Cauchy surface. Since the scalar product (6.1) does not depend on the choice of \( \Sigma \), it is convenient in our case to choose \( \Sigma = J^- \cup H^- \), where \( J^- \) is the past null infinity and \( H^- \) is the past horizon. (For details, see e.g. [14]).

Using solutions of the radial and angular equations we define the following normalized solutions of the field equation (3.2) (in coordinates \((t, r, \theta, \phi, \psi)\))

\[ u_A^{\in}(x) = \left[ \frac{r}{4\pi \omega (r^2 + a^2)(r^2 + b^2)} \right]^{1/2} e^{-i\omega t} R_{\ell m k}^{\in}(r|\omega) Y_{\ell m k}(\theta, \phi, \psi|\omega), \]  

(6.2)

\[ u_A^{\up}(x) = \left[ \frac{r}{4\pi \omega (r^2 + a^2)(r^2 + b^2)} \right]^{1/2} e^{-i\omega t} R_{\ell m k}^{\up}(r|\omega) Y_{\ell m k}(\theta, \phi, \psi|\omega). \]  

(6.3)

Here \( \Lambda = \{\omega \ell m k\} \). The solutions \( u_A^{\in} \) are defined for \( \omega > 0 \). The solutions \( u_A^{\up} \) are naturally defined for \( \varpi > 0 \). For superradiant modes, that is for \( 0 < \omega < m\Omega \), one uses solutions \( u_{-\omega \ell - m - k}^{\up} \).

The unrenormalized expectation value of the stress-energy tensor in the state of the Unruh vacuum is (see [13])

\[
\langle U|\hat{T}_{\mu\nu}|U \rangle = \sum_{j} \left[ \int_{0}^{\infty} d\omega \ coth \left( \frac{\pi \varpi}{\kappa} \right) T_{\mu\nu}[u_A^{\up}, \tilde{u}_A^{\up}] + \int_{0}^{\infty} d\omega \ T_{\mu\nu}[u_A^{\in}, \tilde{u}_A^{\in}] \right],
\]  

(6.4)
where \( \kappa \) is the surface gravity and

\[
T_{\mu\nu}[u,\bar{u}] = \left( \frac{1}{2} - \xi \right) (u_{\mu} \bar{u}_{\nu} + u_{\nu} \bar{u}_{\mu}) - \xi (u_{\mu\nu} \bar{u} + u \bar{u}_{\mu\nu}) + \left( -\frac{1}{2} + 2\xi \right) g_{\mu\nu} u^{\lambda} \bar{u}^{\lambda}.
\]

Here \( \xi \) is the parameter of non-minimal coupling. For the conformal field in 5-dimensional spacetime \( \xi = 3/16 \) and \( T_{\mu\nu}[u,\bar{u}] = 0 \).

Let us define the following expressions for the energy and angular momentum density fluxes at infinity,

\[
\varepsilon = -\langle U \mid \hat{T}_{\mu\nu} \rangle \xi^\mu \xi^\nu, \quad (6.6)
\]

\[
j = -\langle U \mid \hat{T}_{\mu\nu} \rangle \xi_\phi^\mu \xi_\phi^\nu. \quad (6.7)
\]

Here \( n^\mu \) is a unit vector in \( r \) direction at infinity and we denoted by \( \xi_t^\mu \) and \( \xi_\phi^\mu \) the Killing vectors which generate translation in time \( t \) and rotation in an \( \phi \) direction. Substituting the asymptotics of functions \( u^\text{in}_\Lambda \) and \( u^\text{up}_\Lambda \) into (6.4) one gets for the renormalized value of fluxes (see [13])

\[
\varepsilon(\theta) \sim \frac{1}{8\pi^3 r^3} \sum_{\ell,m,k} \int_0^\infty \frac{\omega^2 \, d\omega}{\omega (e^{2\pi \omega / \kappa} - 1)} \left| t^\text{up}_{\ell mk}(\omega) \right|^2 \frac{|S^m_{\ell k}(\theta | \alpha)|^2}{\cos \theta}, \quad (6.8)
\]

\[
j(\theta) \sim \frac{1}{8\pi^3 r^3} \sum_{\ell,m,k} \int_0^\infty \frac{m \omega \, d\omega}{\omega (e^{2\pi \omega / \kappa} - 1)} \left| t^\text{up}_{\ell mk}(\omega) \right|^2 \frac{|S^m_{\ell k}(\theta | \alpha)|^2}{\cos \theta}. \quad (6.9)
\]

As we already mentioned, in the case of \( a = b \neq 0 \) the angular harmonics \( S^m_{\ell k} \) are the same as the angular harmonics in the absence of rotation. However, the radial equations (and therefore the gray-body factors) are different for these two cases. Because of that, the energy and angular momentum fluxes differ from those derived in the non-rotating case.

In the degenerate case \( a = b \neq 0 \), we have:

\[
\varepsilon(\theta) \sim \frac{1}{8\pi^3 r^3} \sum_{\ell,m,k} \int_0^\infty \frac{\omega^2 \, d\omega}{\omega (e^{2\pi \omega / \kappa} - 1)} \left| t^\text{up}_{\ell mk}(\omega) \right|^2 (1-z)^m (1+z)^k \left( B^{|m|,|k|}_\ell(z) \right)^2 \left( P^{|m|,|k|}_\ell(z) \right)^2, \quad (6.10)
\]

\[
j(\theta) \sim \frac{1}{8\pi^3 r^3} \sum_{\ell,m,k} \int_0^\infty \frac{m \omega \, d\omega}{\omega (e^{2\pi \omega / \kappa} - 1)} \left| t^\text{up}_{\ell mk}(\omega) \right|^2 (1-z)^m (1+z)^k \left( B^{|m|,|k|}_\ell(z) \right)^2 \left( P^{|m|,|k|}_\ell(z) \right)^2. \quad (6.11)
\]

where \( B^{|m|,|k|}_\ell \) is defined in (4.18) and \( z = \cos(2\theta) \).

By integrating over the angle variables (over 3-sphere boundary at infinity) we obtain the expressions for the total energy and angular moment emission

\[
\dot{E} = \frac{1}{2\pi} \sum_{\ell,m,k} \int_0^\infty \frac{\omega^2 \, d\omega}{\omega (e^{2\pi \omega / \kappa} - 1)} \left| t^\text{up}_{\ell mk}(\omega) \right|^2, \quad (6.12)
\]

\[
\dot{J} = \frac{1}{2\pi} \sum_{\ell,m,k} \int_0^\infty \frac{m \omega \, d\omega}{\omega (e^{2\pi \omega / \kappa} - 1)} \left| t^\text{up}_{\ell mk}(\omega) \right|^2. \quad (6.13)
\]
7 Discussion

The results obtained in this paper are important from several points of view. First, they allow one to better understand the dynamics of massless scalar fields propagating near a rotating higher dimensional black holes. The separation of variables which occurs in 5-dimensional scalar field wave equation indicates that separation which occurred in 4-dimensional case was not merely an accident, but it is rather a property which follows from the symmetries of a rotating black hole.

The results are readily applicable to the brane world models where phenomenologically valid rotating higher dimensional black holes can exist. Non-trivial structure of rotational group in four spatial dimensions (like the existence of two parameters of rotation, the notion of invariant planes of rotations rather than axis of rotation etc.) gives rise to rich phenomenology concerning radiation from such black holes. For example, one of the parameters of rotation could be zero, in which case the black hole would be spinning only in one plane. This case is of particular interest in brane world models where in the first approximation the black holes produced in collisions of standard model particles can spin only in the planes defined by the brane where all the standard model fields are confined. However, if we take a backreaction into account, after such a black hole emits higher dimensional graviton into the bulk, it gains the general angular momentum which can not be described with a single parameter of rotation. This makes the general form of rotation inevitable to study. It is interesting to mention that if both parameters of rotation are non-vanishing but equal, the angular equation coincides with that of a non-rotating case. For each of these particular cases, using expressions given in eqs. (6.10) and (6.11), we can calculate the angular distributions as well as the total amount of energy and angular momentum emitted by a black hole.

We demonstrated that similarly to the 4-dimensional case, 5-dimensional rotating black hole allows the superradiance effect. If \( m \) and \( k \) are azimuthal quantum numbers with respect to 2 rotation axes, then the condition of superradiance is \( \omega < m\Omega_a + k\Omega_b \), where \( \Omega_a \) and \( \Omega_b \) are angular velocities. One can expect that another feature of quantum radiation from 4-dimensional rotating black holes, namely its strong spin dependence \([15]\), is also present in the 5-dimensional case. If it occurs then the bulk radiation of gravitons might be the leading channel of the black hole decay. In order to check this conjecture it is necessary to solve higher spin massless field equations in the higher dimensional space-time of a rotating black hole. This is an interesting challenge.
