Abstract

Radiative corrections to neutrino mixing and CP violation are analyzed in the minimal seesaw model with two heavy right-handed neutrinos. We find that textures of the effective Majorana neutrino mass matrix are essentially stable against renormalization effects. Taking account of the Frampton-Glashow-Yanagida ansatz for the Dirac neutrino Yukawa coupling matrix, we calculate the running effects of light neutrino masses, lepton flavor mixing angles and CP-violating phases for both $m_1 = 0$ (normal mass hierarchy) and $m_3 = 0$ (inverted mass hierarchy) cases in the standard model and in its minimal supersymmetric extension. Very instructive predictions for the cosmological baryon number asymmetry via thermal leptogenesis are also given with the help of low-energy neutrino mixing quantities.

I. INTRODUCTION

In the standard model (SM), lepton number conservation is assumed and neutrinos are exactly massless Weyl particles. However, the recent Super-Kamiokande [1], SNO [2], KamLAND [3] and K2K [4] experiments have provided us with very compelling evidence that neutrinos are actually massive and lepton flavors are mixed. The most economical modification of the SM, which can both accommodate neutrino masses and allow lepton number violation to explain the cosmological baryon asymmetry via leptogenesis [5], is to introduce two heavy right-handed neutrinos \(N_{1,2}\) and keep the Lagrangian of electroweak interactions invariant under \(SU(2)_L \times U(1)_Y\) gauge transformation [6–9]. In this case, the Yukawa interactions of leptons are described by

\[
-L_{Y(SM)} = \bar{l}_L Y_l e_R H + \bar{l}_L Y_\nu \nu_R H^c + \frac{1}{2} \bar{\nu}_R M_{\nu R} \nu_R + \text{h.c.},
\]

where \(l_L\) denotes the left-handed lepton doublet; \(e_R\) and \(\nu_R\) stand respectively for the right-handed charged lepton and Majorana neutrino singlets; and \(H\) is the Higgs-boson weak isodoublet (with \(H^c \equiv i \sigma_2 H^*\)). If the minimal supersymmetric standard model (MSSM) is taken into account, one may similarly write out the Yukawa interactions of leptons:

\[
-L_{Y(MSSM)} = \bar{l}_L Y_l e_R H_1 + \bar{l}_L Y_\nu \nu_R H_2 + \frac{1}{2} \bar{\nu}_R M_{\nu R} \nu_R + \text{h.c.},
\]

where \(H_{1,2}\) (with hypercharges \(\pm 1/2\)) are the MSSM Higgs doublets.

Without loss of generality, both the heavy Majorana neutrino mass matrix \(M_{\nu R}\) and the charged-lepton Yukawa coupling matrix \(Y_l\) can be taken to be diagonal, real and positive. In this specific flavor basis, the Dirac neutrino Yukawa coupling matrix \(Y_\nu\) is a complex \(3 \times 2\) rectangular matrix:

\[
Y_\nu = \begin{pmatrix}
a_1 & a_2 \\
b_1 & b_2 \\
c_1 & c_2
\end{pmatrix}.
\]

Below the mass scale of the lightest right-handed neutrino \(N_1\) (denoted as \(M_1\)), \(M_{\nu R}\) can be integrated out of the theory. Such a treatment corresponds to a replacement of the last two terms in \(L_Y\) by a dimension-5 operator, whose coupling matrix takes the seesaw [10] form

\[
\kappa (M_1) = Y_\nu M_{\nu R}^{-1} Y_\nu^T = \begin{pmatrix}
a_1^2 & a_1 b_1 & a_1 c_1 \\
a_1 b_1 & b_1^2 & b_1 c_1 \\
a_1 c_1 & b_1 c_1 & c_1^2
\end{pmatrix} + \begin{pmatrix}
a_2^2 & a_2 b_2 & a_2 c_2 \\
a_2 b_2 & b_2^2 & b_2 c_2 \\
a_2 c_2 & b_2 c_2 & c_2^2
\end{pmatrix}. \]

It has been shown that \(\text{Det}[\kappa (M_1)] = 0\) holds for arbitrary \(a_i, b_i\) and \(c_i\) [11]. This is a very special feature of the minimal seesaw model.

After spontaneous gauge symmetry breaking, the neutral component of \(H\) acquires the vacuum expectation value \(v \approx 174\) GeV. Then one obtains the charged lepton mass matrix
$M_l = v Y_l(M_Z)$ and the light (left-handed) Majorana neutrino mass matrix $M_\nu = v^2 \kappa(M_Z)$ at the electroweak scale $\mu = M_Z$ in the SM. The neutral components of $H_1$ and $H_2$ may similarly acquire the vacuum expectation values $v \cos \beta$ and $v \sin \beta$ at the electroweak symmetry breaking scale. It turns out that $M_l = v \cos \beta Y_l(M_Z)$ and $M_\nu = v^2 \sin^2 \beta \kappa(M_Z)$ in the MSSM. Note that $\kappa(M_Z)$ and $\kappa(M_1)$ can be related to each other via the following one-loop renormalization-group equation (RGE) [12]:

$$16\pi^2 \frac{d \kappa}{dt} = \alpha \kappa + C \left[ (Y_l Y_l^\dagger) \kappa + \kappa (Y_l Y_l^\dagger)^T \right],$$

(5)

where $t = \ln(\mu/M_1)$ with $\mu$ being the renormalization scale. In the SM [13] or in its minimal supersymmetric extension [14],

$$C_{SM} = -\frac{3}{2},$$

$$\alpha_{SM} = -3 g_2^2 + 6 f_t^2 + \lambda$$

(6)

or

$$C_{MSSM} = 1,$$

$$\alpha_{MSSM} = -\frac{6}{5} g_1^2 - 6 g_2^2 + 6 f_t^2,$$

(7)

where $g_{1,2}$ denote the gauge couplings, $f_t$ denotes the top-quark Yukawa coupling, and $\lambda$ denotes the Higgs self-coupling in the SM \(^1\). If $M_1 \gg M_Z$ holds, some deviation of $\kappa(M_Z)$ from $\kappa(M_1)$ must take place.

Apparently, it is $\kappa(M_Z)$ or $M_\nu$ that governs the low-energy phenomenology of neutrino masses and lepton flavor mixing, because $Y_l$ keeps diagonal in the RGE running from $M_1$ to $M_Z$. In all recent analyses of the minimal seesaw model [6–9], however, the quantum corrections to $\kappa$ at the electroweak scale have been neglected for the sake of simplicity and illustration. The importance of RGE effects on the evaluation of baryogenesis via leptogenesis in the bottom-up approach (i.e., from low energies to the mass scale of heavy right-handed neutrinos) has been pointed out by some authors [15], but a careful analysis of such effects in the minimal seesaw model has not been done.

The purpose of this paper is to examine the stability of $\kappa$ against radiative corrections in the minimal seesaw model. We find that the texture of $\kappa$ is essentially stable in the RGE evolution from $M_1$ to $M_Z$. To be specific, we calculate the running effects of neutrino masses, lepton flavor mixing angles and CP-violating phases by taking account of the Frampton-Glashow-Yanagida (FGY) ansatz for $Y_\nu$ [6]. The cosmological baryon number asymmetry via leptogenesis is also calculated at the scale $\mu = M_1$ with the help of low-energy neutrino mixing quantities.

\(^1\)In the expression of $\alpha_{SM}$, we have neglected very small contributions from the lighter quarks and charged leptons. Similarly, the up- and charm-quark Yukawa couplings have been neglected in the expression of $\alpha_{MSSM}$. 

3
II. RGE RUNNING EFFECTS FROM $M_1$ TO $M_Z$

In the flavor basis chosen above, one may simplify the RGE in Eq. (5) and get the radiative corrections to $\kappa$ at $M_Z$. Let us define the evolution functions

$$I_\alpha = \exp \left[ -\frac{1}{16\pi^2} \int_0^{\ln(M_1/M_Z)} \alpha(t) \, dt \right],$$

$$I_l = \exp \left[ -\frac{C}{16\pi^2} \int_0^{\ln(M_1/M_Z)} f^2_l(t) \, dt \right],$$

(8)

where $f_l$ (for $l = e, \mu, \tau$) denote the Yukawa coupling eigenvalues of charged leptons. Then we solve Eq. (5) and arrive at

$$\kappa(M_Z) = I_\alpha \begin{pmatrix} I_e & 0 & 0 \\ 0 & I_\mu & 0 \\ 0 & 0 & I_\tau \end{pmatrix} \kappa(M_1) \begin{pmatrix} I_e & 0 & 0 \\ 0 & I_\mu & 0 \\ 0 & 0 & I_\tau \end{pmatrix}. \quad (9)$$

The overall factor $I_\alpha$ only affects the magnitudes of light neutrino masses, while $I_l$ (for $l = e, \mu, \tau$) can modify both neutrino masses and lepton flavor mixing parameters [16]. The strong mass hierarchy of three charged leptons (i.e., $f_e < f_\mu < f_\tau$) implies that $I_e < I_\mu < I_\tau$ (SM) or $I_e > I_\mu > I_\tau$ (MSSM) holds below the scale $M_1$.

Two comments on the consequences of Eq. (9) are in order.

1) The determinant of $\kappa$, which vanishes at the scale $M_1$, keeps vanishing at the scale $M_Z$. This point can clearly be seen from the relation

$$\text{Det}[\kappa(M_Z)] = I_\alpha^3 I_e^2 I_\mu^2 I_\tau^2 \text{Det}[\kappa(M_1)]. \quad (10)$$

Because of $|\text{Det}[\kappa(M_Z)]| = m_1 m_2 m_3$, where $m_i$ (for $i = 1, 2, 3$) denote the masses of three light neutrinos, one may conclude that one of the three neutrino masses must vanish. Considering that $m_2 > m_1$ is required by current solar neutrino oscillation data [2], we are left with either $m_1 = 0$ (normal mass hierarchy) or $m_3 = 0$ (inverted mass hierarchy).

2) Comparing between Eqs. (4) and (9), we find that the radiative correction to $\kappa$ can effectively be expressed as the RGE running effects in $a_i, b_i$ and $c_i$ of $Y_\nu$ (in the assumption that $M_1$ keeps unchanged):

$$a_i(M_Z) = I_e \sqrt{I_\alpha} a_i(M_1),$$

$$b_i(M_Z) = I_\mu \sqrt{I_\alpha} b_i(M_1),$$

$$c_i(M_Z) = I_\tau \sqrt{I_\alpha} c_i(M_1),$$

(11)

where $i = 1$ or 2. These simple relations imply that possible texture zeros of $\kappa$ at $M_1$ remain the same at $M_Z$, at least at the one-loop level of RGE evolution. Hence the texture of $\kappa$ is essentially stable against quantum corrections from $M_1$ to $M_Z$.

For illustration, we typically take $m_t(M_Z) \approx 181$ GeV [17] to calculate the evolution functions $I_\alpha$ and $I_l$ (for $l = e, \mu, \tau$). It is found that $I_e \approx I_\mu \approx 1$ is an excellent approximation both in the SM and in the MSSM. Thus the RGE running of $\kappa$ is mainly governed by $I_\alpha$. 

4
and $I_\tau$. The behaviors of $I_\alpha$ and $I_\tau$ changing with $M_1$ are shown in Fig. 1. One can see that $I_\tau \approx 1$ is also a good approximation, in particular in the SM. Hence the evolution of light neutrino masses must be dominated by $I_\alpha$, which may significantly deviate from unity in the SM with reasonable values of the Higgs mass $m_H$ and in the MSSM with large values of $\tan \beta$.

The effect of $I_\tau$ in the running of $\kappa$ will certainly lead to the evolution of the lepton flavor mixing matrix $V$. At the electroweak scale, $V$ is defined to diagonalize the neutrino mass matrix $M_\nu$ in the chosen flavor basis; i.e., $V^\dagger M_\nu V^* = \text{Diag}\{m_1, m_2, m_3\}$. A commonly-used parametrization of $V$ is

\[
V = \begin{pmatrix}
c_x c_z & s_x c_z & s_z \\
-c_x s_y s_z - s_x c_y e^{-i\delta} & -s_x s_y s_z + c_x c_y e^{-i\delta} & s_y c_z \\
-c_x c_y s_z + s_x s_y e^{-i\delta} & -s_x c_y s_z - c_x s_y e^{-i\delta} & c_y c_z
\end{pmatrix} \begin{pmatrix}
e^{i\rho} & 0 & 0 \\
0 & e^{i\sigma} & 0 \\
0 & 0 & 1
\end{pmatrix},
\]

where $s_x \equiv \sin \theta_x$, $c_x \equiv \cos \theta_x$, and so on. The Dirac phase $\delta$ measures CP violation in normal neutrino oscillations, while the Majorana phases $\rho$ and $\sigma$ are relevant to the neutrinoless double beta decay [18]. Current data on solar, atmospheric and reactor neutrino oscillations yield $\theta_x \approx 32^\circ$ and $\theta_y \approx 45^\circ$ (best-fit values [19]) as well as $\theta_z < 12^\circ$ [20]. The typical mass-squared differences of solar and atmospheric neutrino oscillations read as $\Delta m^2_{\text{sun}} \equiv m_2^2 - m_1^2 \approx 7.13 \times 10^{-5}$ eV$^2$ and $\Delta m^2_{\text{atm}} \equiv |m_3^2 - m_2^2| \approx 2.6 \times 10^{-3}$ eV$^2$ (best-fit values [19]), respectively. Following Ref. [21] and Ref. [22], one may derive the RGEs of $(m_1, m_2, m_3)$, $(\theta_x, \theta_y, \theta_z)$ and $(\delta, \rho, \sigma)$ with the help of Eq. (5). The relevant analytical results can considerably be simplified, if the smallness of $s_x$ and $\Delta m^2_{\text{sun}}/\Delta m^2_{\text{atm}}$ is taken into account. It should be noted that the parametrization of $V$ used here is somehow different from that taken in Ref. [22]. To be complete and explicit, we present our approximate analytical expressions of $(\hat{m}_1, \hat{m}_2, \hat{m}_3)$, $(\hat{\theta}_x, \hat{\theta}_y, \hat{\theta}_z)$ and $(\hat{\delta}, \hat{\rho}, \hat{\sigma})$ in Appendix A. Because $m_1 = 0$ or $m_3 = 0$ must hold in the minimal seesaw model under consideration, it is actually possible to obtain much simpler results from Eqs. (A1)–(A4).

### III. FGY Ansatz and Radiative Corrections

The minimal seesaw model itself has no restriction on the structure of $Y_\nu$. In Ref. [6], Frampton, Glashow and Yanagida (FGY) have conjectured that $Y_\nu$ may have two texture zeros: $a_2 = c_1 = 0$ or $a_2 = b_1 = 0$, which could stem from an underlying horizontal flavor symmetry. The texture of $\kappa(M_1)$ in Eq. (4) can then be simplified:

\[
\kappa(M_1) = \begin{pmatrix}
\frac{a_1^2}{M_1} & \frac{a_1 b_1}{M_1} & 0 \\
\frac{a_1 b_1}{M_1} & \frac{b_1^2}{M_1} + \frac{b_2^2}{M_2} & \frac{b_2 c_2}{M_2} \\
0 & \frac{b_2 c_2}{M_2} & \frac{c_2^2}{M_2}
\end{pmatrix}
\]

in the $a_2 = c_1 = 0$ case; or
\[
\kappa(M_1) = \begin{pmatrix}
\frac{a_1^2}{M_1} & 0 & \frac{a_1 c_1}{M_1} \\
0 & \frac{b_2^2}{M_2} & \frac{b_2 c_2}{M_2} \\
\frac{a_1 c_1}{M_1} & \frac{b_2 c_2}{M_2} & \frac{c_1^2}{M_1} + \frac{c_2^2}{M_2}
\end{pmatrix}
\] (14)

in the \(a_2 = b_1 = 0\) case. Note that the \(a_1 = c_2 = 0\) and \(a_1 = b_2 = 0\) cases are respectively equivalent to the \(a_2 = c_1 = 0\) and \(a_2 = b_1 = 0\) cases in phenomenology. Note also that the \(b_2 = c_1 = 0\) (or \(b_1 = c_2 = 0\)) case, in which the (2,3) and (3,2) matrix elements of \(\kappa(M_1)\) vanish, is not favored by current neutrino oscillation data [11] and will not be taken into account in the subsequent discussions. In addition, the two instructive patterns of \(\kappa(M_1)\) in Eqs. (13) and (14) are expected to have very similar consequences on neutrino masses, lepton flavor mixing angles and CP-violating phases at low-energy scales (See Ref. [8] for some detailed discussions). We shall therefore concentrate only on the FGY ansatz given in Eq. (13) later on.

It is worth remarking that \(a_1, b_1, 2\) and \(c_2\) in Eq. (13) are all complex parameters. Given the specific parametrization of \(V\) in Eq. (12), it is straightforward to obtain

\[
\kappa(M_Z) = \frac{M_\nu}{\Omega} = V \begin{pmatrix}
\frac{m_1}{\Omega} & 0 & 0 \\
0 & \frac{m_2}{\Omega} & 0 \\
0 & 0 & \frac{m_3}{\Omega}
\end{pmatrix} V^T,
\] (15)

where \(\Omega \equiv v^2\) in the SM and \(\Omega \equiv v^2 \sin^2 \beta\) in the MSSM. Then the phases of \(a_1, b_1, 2\) and \(c_2\) can be determined in terms of \(\delta, \rho\) and \(\sigma\). In Refs. [6,8], the phase convention \(\arg(a_1) = \arg(b_2) = \arg(c_2) = 0\) has been taken. We do not adopt this phase convention in the present work. The physical results predicted by the FGY ansatz are certainly independent of any specific phase convention.

Note that \(\kappa(M_Z)\) takes the same texture as \(\kappa(M_1)\), and their corresponding matrix elements are related to each other via Eq. (11). This observation implies that the bottom-up approach should be more convenient for the numerical evaluation of radiative corrections — namely, we determine the parameters of the FGY ansatz at low energies by using current neutrino oscillation data, and then run them to the mass scale \(M_1\) to examine how large the renormalization effects are.

**A. Normal neutrino mass hierarchy \((m_1 = 0)\)**

It is rather obvious that \(m_1 = 0\) leads to \(m_2 = \sqrt{\Delta m^2_{\text{sun}}} \approx 8.4 \times 10^{-3} \text{ eV}\) and \(m_3 = \sqrt{\Delta m^2_{\text{sun}} + \Delta m^2_{\text{atm}}} \approx 5.2 \times 10^{-2} \text{ eV}\). Furthermore, \(m_1 = 0\) implies that only the Majorana phase \(\sigma\) is physically meaningful. Taking account of the texture zero \((M_\nu)_{13} = 0\), one can determine both \(\delta\) and \(\sigma\) in terms of the flavor mixing angles \((\theta_x, \theta_y, \theta_z)\) and the mass ratio \(\xi \equiv m_2/m_3 \approx 0.16\) [8]:

\[ \delta = \arccos \left[ \frac{c_y s_x^2 - \xi c_y^2 + s_x c_y^2 s_z^2}{2 c_x s_x c_y s_z} \right], \]
\[ \sigma = \frac{1}{2} \arctan \left[ \frac{c_y s_x \sin \delta}{s_x c_y s_z + c_x s_y \cos \delta} \right]. \]

(16)

Because \(|\cos \delta| \leq 1\) must hold, we find that \(\theta_z\) is restricted to a very narrow range: \(4.0^\circ \lesssim \theta_z \lesssim 4.4^\circ\) (i.e., \(0.070 \lesssim s_z \lesssim 0.077\)). The implication of this result is that the FGY ansatz with \(m_1 = 0\) will simply be excluded, if the experimental value of \(\theta_z\) does not really lie in the predicted region.

As a direct consequence of \(m_1 = 0\), the RGEs of \(m_1, m_2\) and \(m_3\) in Eq. (A1) may be simplified to

\[ \dot{m}_1 = 0, \]
\[ \dot{m}_2 \approx \frac{1}{16\pi^2} \left( \alpha + 2CF_x^2 c_y^2 s_x^2 \right) m_2, \]
\[ \dot{m}_3 \approx \frac{1}{16\pi^2} \left( \alpha + 2CF_x^2 c_y^2 \right) m_3. \]

(17)

One can see that \(m_1 = 0\) holds at any energy scale between \(M_Z\) and \(M_1\), and the running behaviors of \(m_2\) and \(m_3\) are essentially identical (dominated by the term proportional to \(\alpha\)).

To illustrate, we show the ratio \(R \equiv m_2(M_Z)/m_2(M_1)\) changing with \(m_H\) in the SM or with \(\tan \beta\) in the MSSM in Fig. 2, where \(M_1 = 10^{14}\) GeV is typically taken. It becomes clear that \(R_{m_1=0} \approx 1\) is an excellent approximation in the SM, and it is also a good approximation in the MSSM.

We remark that \(m_2/m_3\) is approximately unchanged in the RGE evolution from \(M_Z\) to \(M_1\) — in other words, \(\xi \approx 0.16\) is nearly a constant. It is then possible to simplify the RGEs of \((\theta_x, \theta_y, \theta_z)\) and \((\delta, \sigma)\) in Eqs. (A2) and (A3) up to \(\mathcal{O}(\xi)\) or \(\mathcal{O}(s_z)\):

\[ \dot{\theta}_x \approx -\frac{C F_x^2}{16\pi^2} s_x c_y s_x^2, \]
\[ \dot{\theta}_y \approx -\frac{C F_x^2}{16\pi^2} s_y c_y \left( 1 + 2 \xi c_x^2 \cos \delta \right), \]
\[ \dot{\theta}_z \approx -\frac{CF_x^2}{8\pi^2} \xi s_x c_x c_y s_y; \]

(18)

and

\[ \dot{\sigma} \approx \frac{CF_x^2}{8\pi^2} \left( s_x c_x c_y c_y \frac{\xi}{s_z} \right) \xi \sin \delta, \]
\[ \dot{\delta} \approx \frac{CF_x^2}{8\pi^2} \left[ s_x c_x c_y c_y \frac{\xi}{s_z} + c_x^2 \left( c_y^2 - s_y^2 \right) \right] \xi \sin \delta. \]

(19)

In obtaining Eqs. (18) and (19), we have considered the fact that \(\xi \sim 2s_z\) holds at \(M_Z\). One can see that the running effects of three mixing angles and two CP-violating phases are all governed by \(f_\tau^2\). Because of \(f_\tau^2 \approx 10^{-4}\) in the SM, the evolution of \((\theta_x, \theta_y, \theta_z)\) and \((\sigma, \delta)\) is negligibly small. When \(\tan \beta\) is sufficiently large (e.g., \(\tan \beta \sim 50\)) in the MSSM,
however, $f_\tau^2 \approx 10^{-4}/\cos^2 \beta$ can be of $O(0.1)$ and even close to unity — in this case, some small variation of $(\theta_x, \theta_y, \theta_z)$ and $(\sigma, \delta)$ due to the RGE running from $M_Z$ to $M_1$ will appear. Let us define $\Delta \theta_i \equiv \theta_i(M_1) - \theta_i(M_Z)$ (for $i = x, y, z$), $\Delta \delta \equiv \delta(M_1) - \delta(M_Z)$ and $\Delta \sigma \equiv \sigma(M_1) - \sigma(M_Z)$. The numerical results of $\Delta \theta_i/\theta_i(M_Z)$, $\Delta \delta/\delta(M_Z)$ and $\Delta \sigma/\sigma(M_Z)$ are shown in Fig. 3 for the MSSM with different values of $M_1$ and tan $\beta$. We see that the ratio $\Delta \theta_z/\theta_z(M_Z)$ is most sensitive to the RGE running, but its magnitude is less than 10% even if $M_1 = 10^{14}$ GeV and tan $\beta = 50$ are taken. Thus we conclude that the RGE effects on three flavor mixing angles and two CP-violating phases are practically negligible in the FGY ansatz with $m_1 = 0$.

B. Inverted neutrino mass hierarchy ($m_3 = 0$)

If $m_3 = 0$ holds, we will arrive at $m_1 = \sqrt{\Delta m^2_{\text{atm}} - \Delta m^2_{\text{sun}}} \approx 5.0 \times 10^{-2}$ eV and $m_2 = \sqrt{\Delta m^2_{\text{atm}}} \approx 5.1 \times 10^{-2}$ eV. In this case, only the difference of two Majorana CP-violating phases $\sigma - \rho \equiv \sigma'$ is physically meaningful. Again, the texture zero $(M_\nu)_{13} = 0$ allows us to determine $\delta$ and $\sigma'$ in terms of the flavor mixing angles $(\theta_x, \theta_y, \theta_z)$ and the mass ratio $\zeta \equiv m_1/m_2 \approx 0.98$ [8]:

$$\delta = \arccos \left[ \frac{(\zeta^2 c_x^4 - s_x^4) c_y^2 s_y^2 + (\zeta^2 - 1) s_x^2 c_x^2 s_y^2}{2 s_x c_x (s_x^2 + \zeta^2 c_x^2) s_y c_y s_z} \right],$$

$$\sigma' = -\frac{1}{2} \text{arctan} \left[ \frac{s_y c_y s_z \sin \delta}{s_x c_x (s_y^2 - c_y^2 s_z^2) + (s_x^2 - c_x^2) s_y c_y s_z \cos \delta} \right].$$

Different from the $m_1 = 0$ case, $|\cos \delta| \leq 1$ does not impose significant constraints on the magnitude of $\theta_z$ via Eq. (20), except that it requires $\theta_z > 0.36^\circ$ [8]. Hence the FGY ansatz with $m_3 = 0$ is not very sensitive to the measurement of $\theta_z$.

As a straightforward consequence of $m_3 = 0$, the RGEs of $m_1$, $m_2$ and $m_3$ in Eq. (A1) can be simplified to

$$\dot{m}_1 \approx \frac{1}{16\pi^2} \left( \alpha + 2C f_\tau^2 s_x^2 s_y^2 \right) m_1,$$

$$\dot{m}_2 \approx \frac{1}{16\pi^2} \left( \alpha + 2C f_\tau^2 c_x^2 s_y^2 \right) m_2,$$

$$\dot{m}_3 = 0.$$  

Again, $m_3 = 0$ holds at any energy scale between $M_Z$ and $M_1$; and the running behaviors of $m_1$ and $m_2$ are essentially the same. Fig. 2 illustrates the ratio $R \equiv m_2(M_Z)/m_2(M_1)$ as a function of $m_H$ in the SM or of tan $\beta$ in the MSSM. We see that $R_{m_3=0} \approx R_{m_1=0} \approx I_\alpha$ holds to an excellent degree of accuracy in the SM and to a good degree of accuracy in the MSSM. These numerical results confirm that the evolution of three neutrino masses is dominated by $I_\alpha$, as observed in section II.

While $\zeta$ is approximately a constant in the RGE running from $M_Z$ to $M_1$, it is not small. In this case, we simplify Eqs. (A2) and (A3) up to $O(s_\beta)$ so as to get the leading-order RGEs of $(\theta_x, \theta_y, \theta_z)$ and $(\delta, \sigma')$ as follows:
\[
\dot{\theta}_x \approx - \frac{C f^2}{16 \pi^2} \left( \frac{1 + \zeta^2 + 2 \zeta \cos 2\sigma'}{1 - \zeta^2} \right) s_x c_x s^2_y , \\
\dot{\theta}_y \approx \frac{C f^2}{16 \pi^2} s_y c_y , \\
\dot{\theta}_z \approx \frac{C f^2}{16 \pi^2} c_y s_z ; \\
(22)
\]

and

\[
\dot{\sigma}' \approx \frac{C f^2}{8 \pi^2} \left( \frac{c^2_x - s^2_y}{1 - \zeta^2} \right) \zeta s^2_y \sin 2\sigma' , \\
\dot{\delta} \approx \frac{C f^2}{8 \pi^2} \left( \frac{1}{1 - \zeta^2} \right) \zeta s^2_y \sin 2\sigma'. \\
(23)
\]

Unlike the \( m_1 = 0 \) case, the RGE running effects of \( \theta_x, \delta \) and \( \sigma' \) are enhanced by a factor \( 1/(1 - \zeta^2) \approx 25 \) in the \( m_3 = 0 \) case. One might naively expect that the magnitudes of \( \Delta \theta_x \equiv \theta_x(M_1) - \theta_x(M_Z) \), \( \Delta \delta \equiv \delta(M_1) - \delta(M_Z) \) and \( \Delta \sigma' \equiv \sigma'(M_1) - \sigma'(M_Z) \) are appreciable. Because of \( \sin \sigma' \sim \mathcal{O}(s_x) \), however, \( \delta \) and \( \sigma' \) in Eq. (23) are actually suppressed. Therefore, only \( \theta_x \) is likely to be sensitive to the RGE evolution from \( M_Z \) to \( M_1 \). We plot the numerical results of \( \Delta \theta_x/\theta_x(M_Z) \) (for \( i = x, y, z \)), \( \Delta \delta/\delta(M_Z) \) and \( \Delta \sigma'/\sigma'(M_Z) \) in Fig. 4 for the SM and in Fig. 5 for the MSSM. One can see that the RGE effects on three flavor mixing angles and two CP-violating phases are negligibly small in the SM, but they may become significant in the MSSM if both \( M_1 \) and \( \tan \beta \) are sufficiently large. In the latter case, \( \theta_x(M_1) \) is even possible to approach zero — this point has indeed been observed by some authors beyond the minimal seesaw model [23]. We conclude that the near degeneracy between \( m_1 \) and \( m_2 \) in the \( m_3 = 0 \) case may give rise to significant RGE running effects on the mixing angle \( \theta_x \) in the MSSM, and the evolution of CP-violating phases \( \delta \) and \( \sigma' \) can also be appreciable if both \( M_1 \) and \( \tan \beta \) take properly large values.

**IV. COSMOLOGICAL BARYON NUMBER ASYMMETRY**

Lepton number violation induced by the third term of \( \mathcal{L}_Y \) in Eq. (1) or Eq. (2) allows decays of the heavy Majorana neutrinos \( N_i \) (for \( i = 1 \) and \( 2 \)) to happen: \( N_i \rightarrow l + h \) and \( N_i \rightarrow \bar{l} + h^c \), where \( h = H \) in the SM or \( h = H_2^s \) in the MSSM. Because each decay mode occurs at both tree and one-loop levels (via the self-energy and vertex corrections), the interference between these two decay amplitudes may result in a CP-violating asymmetry \( \varepsilon_i \) between \( N_i \rightarrow l + h \) and its \( CP \)-conjugated process [5]. If the masses of \( N_1 \) and \( N_2 \) are hierarchical (i.e., \( M_1 \ll M_2 \)), the interactions of \( N_1 \) can be in thermal equilibrium when \( N_2 \) decays. The asymmetry \( \varepsilon_2 \) is therefore erased before \( N_1 \) decays, and only the asymmetry \( \varepsilon_1 \) produced by the out-of-equilibrium decay of \( N_1 \) survives. In the flavor basis chosen above, we have

\[
\varepsilon_1 \equiv \frac{\Gamma(N_1 \rightarrow l + h) - \Gamma(N_1 \rightarrow \bar{l} + h^c)}{\Gamma(N_1 \rightarrow l + h) + \Gamma(N_1 \rightarrow \bar{l} + h^c)} \\
\approx \frac{C'}{8\pi} \cdot \frac{M_1}{M_2} \cdot \frac{\text{Im} \left[ (Y^i_1 Y^e_\nu)_{12} \right]^2}{(Y^i_3 Y^e_\nu)_{11}} , \\
(24)
\]
where $C'_{\text{SM}} = -3/2$ and $C'_{\text{MSSM}} = -3$ [24]. Taking account of Eq. (3) with $a_2 = c_1 = 0$, we immediately arrive at

$$
(Y_\nu^T Y_\nu)_{11} = |a_1(M_1)|^2 + |b_1(M_1)|^2
\approx \frac{1}{I_\alpha} \left[ |a_1(M_Z)|^2 + |b_1(M_Z)|^2 \right],
$$

$$
(Y_\nu^T Y_\nu)_{12} = b_1^*(M_1) \cdot b_2(M_1)
\approx \frac{1}{I_\alpha} [b_1^*(M_Z) \cdot b_2(M_Z)],
$$

(25)

where $I_\epsilon \approx I_\mu \approx 1$ has been used as an excellent approximation.

In the literature, $\varepsilon_1$ was calculated by neglecting the RGE running effects of neutrino masses, lepton flavor mixing angles and CP-violating phases from $M_Z$ to $M_1$ (i.e., $I_\alpha \approx 1$ was naively taken). Such an oversimplification leads to the CP-violating asymmetry

$$
\hat{\varepsilon}_1 \approx \frac{C'}{8\pi \Omega} \cdot \frac{M_1 |(\nu_\nu)_{12}|^2 |(\nu_\nu)_{23}|^2}{|((\nu_\nu)_{11})^2 + |(\nu_\nu)_{12}|^2| |(\nu_\nu)_{33}|} \sin \Phi,
$$

(26)

where $\Omega = v^2$ (SM) or $\Omega = v^2 \sin^2 \beta$ (MSSM), and [8]

$$
\Phi \approx \begin{cases} 
\arctan \left( \frac{\xi s_2^2 c_2^2 \sin 2\sigma}{s_2^2 \xi s_2^2 c_2^2 \cos 2\sigma} \right), & (m_1 = 0), \\
-2\delta, & (m_3 = 0).
\end{cases}
$$

(27)

One can see that $\hat{\varepsilon}_1$ is actually independent of $M_2$, as long as $M_2 \gg M_1$ is satisfied. Then it is straightforward to obtain $\varepsilon_1 \approx \hat{\varepsilon}_1/I_\alpha$ at the mass scale $M_1$. Although $I_\alpha$ is always smaller than unity for $M_1 > M_Z$ (as already shown in Fig. 1), it remains of $\mathcal{O}(1)$ only if reasonable values of $M_1$ and $m_H$ (SM) or $\tan \beta$ (MSSM) are taken. Hence the previously oversimplified approximation $\varepsilon_1 \approx \hat{\varepsilon}_1$ is unable to cause any quantitative disaster.

A nonvanishing CP-violating asymmetry $\varepsilon_1$ may result in a net lepton number asymmetry

$$
Y_L \equiv n_L/s = \varepsilon_1 d/g_*,
$$

where $g_* = 106.75$ (SM) or 228.75 (MSSM) is an effective number characterizing the relativistic degrees of freedom which contribute to the entropy $s$ of the early universe, and $d$ accounts for the dilution effects induced by the lepton-number-violating wash-out processes [24]. If the effective neutrino mass parameter $\bar{m}_1 \equiv (Y_\nu^T Y_\nu)_{11} \Omega/M_1$ [25] lies in the range $10^{-2}$ eV $\lesssim \bar{m}_1 \lesssim 10^3$ eV, one may estimate the value of $d$ by using the following approximate formula [26] $^2$

$$
d \approx 0.3 \left( \frac{10^{-3} \text{eV}}{\bar{m}_1} \right) \left[ \ln \left( \frac{\bar{m}_1}{10^{-3} \text{eV}} \right) \right]^{-0.6}.
$$

(28)

$^2$In view of Eq. (25), we can easily obtain $\tilde{m}_1(M_1) \approx \bar{m}_1(M_Z)/I_\alpha$. It is proper to use $\tilde{m}_1(M_1)$ instead of $\bar{m}_1(M_Z)$ to evaluate the dilution factor $d$ via Eq. (28), but the numerical discrepancy between $\tilde{m}_1(M_1)$ and $\bar{m}_1(M_Z)$ is actually insignificant.
Therefore the size of \( Y_M \) ansatz for the Dirac neutrino Yukawa coupling matrix, we have calculated the RGE running stable against renormalization effects. Taking account of the Frampton-Glashow-Yanagida and vanishing eigenvalues of the effective Majorana neutrino mass matrix are essentially minimal seesaw model with two heavy right-handed neutrinos. It is shown that textures of lepton-flavor-violating processes \( \mu \rightarrow e\gamma, \tau \rightarrow \mu\gamma \), and so on \([29]\).

(1) In the \( m_1 = 0 \) case, current observational data of \( Y_B \) require \( M_1 > 3.1 \times 10^{10} \) GeV (SM) or \( M_1 > 3.4 \times 10^{10} \) GeV (MSSM) for the allowed range of \( \theta_z(M_Z) \). Once this mixing angle is precisely measured at low energies, it is possible to fix the ball-park magnitude of \( M_1 \) in most cases. However, to distinguish between the minimal seesaw SM and its supersymmetric version needs other experimental information (e.g., the MSSM-motivated leptogenesis and avoiding overproduction of gravitinos in the minimal seesaw model with supersymmetry \([29]\)).

(2) In the \( m_3 = 0 \) case, \( M_1 > 2.25 \times 10^{13} \) GeV (SM) or \( M_1 > 2.5 \times 10^{13} \) GeV (MSSM) is required by current observational data of \( Y_B \). The magnitude of \( Y_B \) increases monotonically with \( \theta_z(M_Z) \) for any given value of \( M_1 \). Once \( \theta_z \) is measured at low energies, it is possible to determine the rough value of \( M_1 \). Again, other experimental information is needed in order to distinguish between the minimal seesaw SM and its supersymmetric version.

(3) We remark that there is a potential conflict between achieving successful thermal leptogenesis and avoiding overproduction of gravitinos in the minimal seesaw model with supersymmetry \([29]\). If the mass scale of gravitinos is of \( \mathcal{O}(1) \) TeV, one must have \( M_1 \lesssim 10^8 \) GeV. This limit is completely disfavored in the FGY ansatz with \( M_1 \ll M_2 \), because it would lead to \( Y_B \ll 10^{-10} \). If \( M_1 \) and \( M_2 \) were almost degenerate, a special case which has been discussed in Ref. \([24]\), it would be possible to simultaneously accommodate \( m_{\tilde{G}} \sim \mathcal{O}(1) \) TeV and \( M_1 \lesssim 10^8 \) GeV in the generic supergravity models with minimal seesaw and thermal leptogenesis.

V. SUMMARY

We have analyzed the radiative corrections to neutrino mixing and CP violation in the minimal seesaw model with two heavy right-handed neutrinos. It is shown that textures and vanishing eigenvalues of the effective Majorana neutrino mass matrix are essentially stable against renormalization effects. Taking account of the Frampton-Glashow-Yanagida ansatz for the Dirac neutrino Yukawa coupling matrix, we have calculated the RGE running effects of light neutrino masses, lepton flavor mixing angles and CP-violating phases from \( M_Z \) to \( M_1 \) for both \( m_1 = 0 \) and \( m_3 = 0 \) cases in the SM and its minimal supersymmetric extension. We find that such quantum corrections are not always negligible, and they should be taken into consideration in order to quantitatively test the FGY ansatz. We have also discussed thermal leptogenesis in the minimal seesaw model with \( M_1 \ll M_2 \). Very instructive predictions for the cosmological baryon number asymmetry are obtained with the help of low-energy neutrino mixing quantities. We conclude that a precise measurement of the
mixing angle $\theta_z$ in reactor- and accelerator-based neutrino oscillation experiments will be extremely helpful to examine the FGY scenario and other presently viable ansätze of lepton mass matrices.

APPENDIX A: ANALYTICAL APPROXIMATIONS OF THE RGES FOR NEUTRINO MASSES AND LEPTON FLAVOR MIXING PARAMETERS

Following Ref. [21] and taking account of $M_L = V \text{Diag} \{m_1, m_2, m_3 \} V^T$ with the parametrization of $V$ given in Eq. (12), we have derived the one-loop RGEs of $(m_1, m_2, m_3)$, $(\theta_x, \theta_y, \theta_z)$ and $(\delta, \rho, \sigma)$ with the help of Eq. (5). Our analytical results are consistent with those obtained in Ref. [22], where a somehow different parametrization of $V$ has been used. For simplicity, only the approximate expressions of ($\dot{m}_1, \dot{m}_2, \dot{m}_3$), ($\dot{\theta}_x, \dot{\theta}_y, \dot{\theta}_z$) and ($\dot{\delta}, \dot{\rho}, \dot{\sigma}$) up to $O(s_z)$ are presented below.

(1) The running of three neutrino masses:

\[
\dot{m}_1 = \frac{1}{16\pi^2} \left[ \alpha + 2Cf_R^2 \left( s_x^2 s_y^2 + O(s_z) \right) \right] m_1 ,
\]

\[
\dot{m}_2 = \frac{1}{16\pi^2} \left[ \alpha + 2Cf_R^2 \left( c_x^2 s_y^2 + O(s_z) \right) \right] m_2 ,
\]

\[
\dot{m}_3 = \frac{1}{16\pi^2} \left[ \alpha + 2Cf_R^2 c_x^2 c_y^2 \right] m_3 .
\] (A1)

(2) The running of three lepton flavor mixing angles:

\[
\dot{\theta}_x = -\frac{Cf_R^2}{16\pi^2} \left[ m_1^2 + m_2^2 + 2m_1 m_2 \cos 2(\rho - \sigma) \right] \frac{s_x c_x s_y^2 + O(s_z)}{m_2^2 - m_1^2} ,
\]

\[
\dot{\theta}_y = -\frac{Cf_R^2}{16\pi^2} \left[ m_2^2 + m_3^2 + 2m_2 m_3 \cos 2(\delta - \sigma) \right] \frac{c_x s_y c_y}{m_3^2 - m_2^2} ,
\]

\[
\dot{\theta}_z = -\frac{Cf_R^2}{16\pi^2} \left[ \left( \frac{2m_2 m_3 \cos (\delta - 2\sigma)}{m_3^2 - m_2^2} - \frac{2m_1 m_3 \cos (\delta - 2\rho)}{m_3^2 - m_1^2} \right) \frac{s_x c_x s_y c_y + O(s_z)}{m_3^2 - m_1^2} \right] .
\] (A2)

(3) The running of three CP-violating phases:

\[
\dot{\rho} = -\frac{Cf_R^2}{16\pi^2} \left[ \frac{A}{s_z} - \frac{2m_2 m_3 \sin \sigma}{m_3^2 - m_2^2} s_x^2 c_y^2 - \frac{2m_1 m_3 \sin 2\rho}{m_3^2 - m_1^2} c_x^2 c_y^2 \right] ,
\]

\[
\dot{\sigma} = -\frac{Cf_R^2}{16\pi^2} \left[ \frac{A}{s_z} - \frac{2m_2 m_3 \sin \sigma}{m_3^2 - m_2^2} s_x^2 c_y^2 - \frac{2m_1 m_3 \sin 2\rho}{m_3^2 - m_1^2} c_x^2 c_y^2 \right] ,
\]

\[
\dot{\delta} = -\frac{Cf_R^2}{16\pi^2} \left[ \frac{A}{s_z} + B + O(s_z) \right] ,
\] (A3)

where
\[A = s_x c_x s_y c_y \left[ \frac{2m_2 m_3 \sin(\delta - 2\sigma)}{m_3^2 - m_2^2} - \frac{2m_1 m_3 \sin(\delta - 2\rho)}{m_3^2 - m_1^2} \right] - \frac{m_2^2 - m_1^2}{m_3^2 - m_2^2} \cdot \frac{2m_2^2 \sin \delta}{m_3^2 - m_2^2} \cdot \frac{2m_3^2 \sin \delta}{m_3^2 - m_1^2},\]

\[B =\frac{2m_1 m_2 s_y^2 \sin 2(\rho - \sigma)}{m_3^2 - m_1^2}\]

\[-\frac{2m_2 m_3}{m_3^2 - m_2^2} \left[ s_x c_y^2 \sin 2\sigma + c_x^2 (c_y^2 - s_y^2) \sin 2(\delta - \sigma) \right]

\[-\frac{2m_1 m_3}{m_3^2 - m_1^2} \left[ c_x^2 c_y^2 \sin 2\rho + s_x^2 (c_y^2 - s_y^2) \sin 2(\delta - \rho) \right].\]
