Abstract

Motivated by recent disagreements in the context of AdS/CFT, we study the non-planar sector of the BMN correspondence. In particular, we reconsider the energy shift of states with two stringy excitations in light-cone string field theory and explicitly determine its complete perturbative contribution from the impurity-conserving channel. Surprisingly, our result neither agrees with earlier leading order computations, nor reproduces the gauge theory prediction. More than that, it features half-integer powers of the effective gauge coupling $\lambda'$ representing a qualitative difference to gauge theory. Based on supersymmetry we argue that the above truncation is not suited for conclusive tests of the BMN duality.

1 Introduction

In the last two years a lot of progress has been made in understanding the ideas of the AdS/CFT correspondence. The starting point of a long chain of developments marks the BMN duality [1], which connects $\mathcal{N} = 4$ $U(N)$ super Yang-Mills (SYM) in the sector of operators with large $U(1)_R$ charge $J \propto \sqrt{N} \to \infty$ and type IIB string theory on the maximally supersymmetric plane-wave background [2]. In contrast to $AdS_5 \times S^5$, here the worldsheet $\sigma$-model reduces to a free theory in the light-cone gauge and thus, can easily be quantized [3]. Moreover, string interactions can be treated in the context of light-cone string field theory [4, 5, 6].

The parameters of the two sides of the duality are linked via [1, 7]

\[
\frac{1}{(\mu \alpha' p^+)^2} = g_{YM}^2 \frac{N}{J^2} \equiv \lambda' \quad \text{and} \quad 4 \pi g_s (\mu \alpha' p^+)^2 = \frac{J^2}{N} \equiv g_2 ,
\]

and therefore free string theory corresponds to the planar ($g_2 = 0$) sector, while string interactions are identified with non-planar, interacting gauge theory. This statement has been subject to a wide range of tests based on the key relation

\[
\frac{1}{\mu} E_{l.c.} = \Delta - J ,
\]

where $E_{l.c.}$ is the light-cone energy of string states and $\Delta$ denotes the conformal dimension of the dual SYM-operators. In particular for the planar case, $E_{l.c.}$ could explicitly be verified for so-called two-impurity operators (i.e. two stringy excitations) up to two loops [1, 8, 9]; for all-loop arguments see [10, 11]. The extension to the interacting part proved to be much more involved. On the field theory side, the anomalous dimension of two-impurity operators is known up to $O(g_2^2 \lambda'^2)$ [12, 13, 9]

\[
\Delta - J = 2 + \frac{g_2^2}{4 \pi^2} \left[ \left( \frac{1}{12} + \frac{35}{32 \pi^2} \right) \lambda' + \frac{1}{4} \left( \frac{1}{12} + \frac{35}{32 \pi^2} \right)^2 \lambda'^2 + \cdots \right] ,
\]

whereas in light-cone SFT only the leading order energy shift has been computed [14]. Over and above, matrix elements of $H_{l.c.}$ and the dilatation operator $D$ as well as decay widths of one-string states and single-trace operators have been successfully compared to leading order, see e.g. [15]. For more details we refer to the reviews [16] and references therein.

It was subsequently realized, that the BMN correspondence can be generalized in essentially two directions: Curvature corrections to the plane-wave background can be taken into account [17] having their counterpart in $1/J$ corrections of planar BMN gauge theory [18, 19]. On the other hand, a completely new field was established by considering semiclassical string states in $AdS_5 \times S^5$ [20] and the insight that the planar spectrum of SYM operators is governed by an integrable Hamiltonian (long-range) spin chain [21], leading to a vast class of tests, see the review [22] and references therein. Both cases show perfect agreement up to two loops [23], see also [24], but – despite of this tremendous progress – several open questions and puzzles gradually emerged at three loops: In the latter approach, string

\[\text{Here } \mu \text{ denotes the curvature scale of the plane-wave geometry and } p^+ \text{ is the light-cone momentum.}\]
and gauge theory continue to exhibit qualitatively similar structures but start to differ in detail \[25\]. Somewhat more disturbing results have been found in \[17\]: degeneracies present in the gauge theory and crucial for integrability \[9, 19, 26\] are lifted in the near plane-wave background.

These recent developments raise the question whether disagreements do already occur in the BMN duality itself, namely in the non-planar, interacting sector. As was pointed out in \[27\], certain matrix elements of $H_{1c}$ and $D$ seem to mismatch starting at $g_2 \lambda'^2$. This however need not necessarily imply that physical quantities show disagreement as well and deserves a more careful investigation, which we initiate in the present paper. Eventually one would like to compute independently the energy of states with two (stringy) excitations on the string theory side and hopefully reproduce \[13\]. Therefore, in section 2, we briefly introduce some well-known facts about the free theory and explicitly construct the supermultiplet for states with two stringy excitations. Especially we find that states consisting of two fermionic/bosonic oscillators in general mix with each other.

The evaluation of the energy shift $\sim \mathcal{O}(g_2^2)$ demands the knowledge of cubic and quartic terms in the Hamiltonian. We review (section 3) the formulation of the three-string vertex restricted by the superalgebra at order $g_2$ and comment on further constraints on the quartic interaction. In particular, we notice that a term induced by the second order dynamical supercharges cannot a priori be excluded. It is a known fact, that all members of a supermultiplet receive the same energy corrections. Furthermore (section 4), one can show by using the states in the supermultiplet, degenerate perturbation theory becomes redundant. Note, that both statements are only valid when including impurity-conserving and -non-conserving intermediate states. Here, we calculate as a first step the complete perturbative (in $\mu^{-1}$) impurity-conserving contribution for one particular representation. Quite surprisingly our result disagrees with that given in the literature \[14\] and also fails to reproduce the gauge theory prediction \[13\] at two loops. Above all as a qualitative difference to gauge theory the series features not only integer, but also half-integer powers of $\lambda'$. It seems to be apparent that this truncated analysis does not reveal the whole story. We conclude with a discussion.

## 2 The free theory

In this section, we introduce the free theory and its symmetries and analyze the underlying supermultiplet structure. Type IIB string theory on the plane-wave space-time can be quantized in light-cone gauge \[3\] resulting in the Hamiltonian

$$H_2 = \frac{1}{\alpha} \sum_{n \in \mathbb{Z}} \omega_n N_n , \quad (2.1)$$

where $\alpha \equiv \alpha' p^+$ is the light-cone momentum, the frequencies are given by $\omega_n = \sqrt{n^2 + (\mu \alpha)^2}$ and $N_n$ indicates the number operator

$$N_n = a_{n}^{+ i} a_{n}^{i} + a_{n}^{+ i'} a_{n}^{i'} + (\beta_{n}^{+ i} \alpha_{1 \alpha_2}^{i} \beta_{n}^{\dagger} \alpha_{1 \alpha_2}) + (\beta_{n}^{+ i} \alpha_{1 \alpha_2}^{i} \beta_{n}^{\dagger} \alpha_{1 \alpha_2}) . \quad (2.2)$$
Compared to \cite{4} we performed a redefinition of the oscillator basis to have the standard level-matching condition (cf. Appendix A), i.e. the operator $\sum_{n \neq 0} n N_n$ has to vanish on the space of physical states. Here the bosonic oscillators $\alpha_n$ transform as $[4, 1] = [(2, 2), (1, 1)]$ and $[1, 4] = [(1, 1), (2, 2)]$ under the transverse $SO(4) \times SO(4) \simeq SU(2)^2 \times SU(2)^2$ isometry of the plane-wave background, whereas the fermionic oscillators $\beta_n$ give the representations $[(2, 1), (2, 1)]$ and $[(1, 2), (1, 2)]$. Both obey the standard (anti)-commutation relations.

Due to the effective harmonic oscillator potential of the background geometry, the theory possesses an essentially unique $SO(4) \times SO(4)$ singlet ground state $|\alpha\rangle$ (labeled by its light-cone momentum since $P^+$ is a central element of the plane-wave superalgebra) defined by

$$\alpha_n |\alpha\rangle = 0, \quad \beta_n |\alpha\rangle = 0, \quad n \in \mathbb{Z}.$$ (2.3)

Excited states are obtained by acting with the creation oscillators on $|\alpha\rangle$ subject to the level-matching condition and can be organized into multiplets of the plane-wave superalgebra. Its bosonic generators are $H, P^+, P^I, J^{I+}$ ($I = 1, \ldots, 8$) and the angular momentum generators of the transverse $SO(4) \times SO(4) J^{ij}$ and $J^{i', j'}$, while the 32 supersymmetries are generated by $Q^+, \bar{Q}^+$ (both transforming as $[(2, 1), (2, 1)]$ and $[(1, 2), (1, 2)]$ and $Q^-, \bar{Q}^-$ (transforming as $[(2, 1), (1, 2)]$ and $[(1, 2), (2, 1)]$).

On a general eigenstate of $H_2$ in a given irreducible representation of $SO(4) \times SO(4)$ the nontrivial action of generators is as follows: Certain combinations of $P^I$ and $J^{I+}$ add or remove a bosonic zero-mode excitation; this raises or lowers the energy of the state by $\mu$ and is the discretized analog of giving a state transverse momentum. Note, that $P^I$ is not a quantum number in the plane-wave space-time since it does not commute with $H$. Similarly $Q^+$ and $\bar{Q}^+$ add or remove a fermionic zero-mode excitation. This is why not the energy but $C \equiv \sum_{n \neq 0} \omega_n N_n$, which only counts the non-zero-mode (‘stringy’) excitations, is a Casimir of the superalgebra. Finally, the most interesting generators are $Q^-$ and $\bar{Q}^-$; these do not change the number of excitations, commute with $H$ and, therefore transform states of the same energy but different $SO(4) \times SO(4)$ representations into each other. This action of the generators is schematically depicted in Fig. 1. In the following we will call a multiplet containing states with $n$ stringy excitations a ‘$n$–impurity’ multiplet. The simplest example is the ‘zero-impurity’, i.e. supergravity multiplet \cite{28}. In this case the highest weight state is the ground state $|\alpha\rangle$ annihilated by all $Q^-, \bar{Q}^-$ and, therefore, this multiplet is short and protected against quantum corrections through string interactions.

### 2.1 The two-impurity supermultiplet

In contrast to the supergravity multiplet, where the state of lowest energy is unique, for the two-impurity multiplet the states of lowest energy $2^{256}$ are those with two stringy oscillators, schematically

- **bosons**: $\alpha_n^\dagger \alpha_{-n}^\dagger |\alpha\rangle$, $\beta_n^\dagger \beta_{-n}^\dagger |\alpha\rangle$
- **fermions**: $\alpha_n^\dagger \beta_{-n}^\dagger |\alpha\rangle$, $\alpha_{-n}^\dagger \beta_n^\dagger |\alpha\rangle$.

All of these 256 states are linked to each other by acting with half of the dynamical supercharges on a highest weight state which we will explicitly determine below, see also \cite{17} for the discussion in
the case of the near plane-wave background. States with two bosonic oscillators are decomposed into irreducible representations of $SO(4) \times SO(4)$, namely

\[ |[1, 1]| = \frac{1}{2} \alpha_n^{\dagger k} \alpha_{-n}^{\dagger k} |\alpha\rangle , \quad (2.4) \]

\[ |[3^\pm, 1]|^{ij} = \frac{1}{2} \left( \alpha_n^{\dagger i} \alpha_n^{\dagger j} - \alpha_n^{\dagger j} \alpha_n^{\dagger i} \pm \varepsilon^{ijkl} \alpha_n^{\dagger k} \alpha_{-n}^{\dagger l} \right) |\alpha\rangle , \quad (2.5) \]

\[ |[4, 4]|^{ij}_{\pm} = \frac{1 \pm \Omega}{\sqrt{2}} \alpha_n^{\dagger i} \alpha_n^{\dagger j} |\alpha\rangle , \quad (2.6) \]

\[ |[9, 1]|^{ij} = \frac{1}{\sqrt{2}} \left( \alpha_n^{\dagger i} \alpha_n^{\dagger j} + \alpha_n^{\dagger j} \alpha_n^{\dagger i} - \frac{1}{2} \delta^{ij} \alpha_n^{\dagger k} \alpha_{-n}^{\dagger k} \right) |\alpha\rangle , \quad (2.7) \]

and analogously for $(i, j) \to (i', j')$. Here $3^\pm$ indicate the (anti)-selfdual representations. Under worldsheet-parity $\Omega$ (i.e. $n \to -n$) the singlets and the symmetric-traceless representations are even, whereas the (anti)-selfdual are odd. The ($\delta$-function)-normalization\(^2\) of $|[9, 1]|$ is $1 + \frac{1}{2} \delta^{ij}$, all other states are normalized to one.

Two fermionic oscillators lead to the states (cf. Appendix A for our conventions for the $\sigma$-matrices)

\[ |[1, 1]| = \frac{1}{2} (\beta_n^{\dagger})_{\alpha_1 \alpha_2} (\beta_n^{\dagger})_{\alpha_1 \alpha_2} |\alpha\rangle , \quad (2.8) \]

\[ |[3^+, 1]|^{ij} = \frac{1}{2} (\sigma^{ij})^{\dagger \alpha_1 \alpha_2} (\beta_n^{\dagger})_{\alpha_1 \alpha_2} (\beta_n^{\dagger})_{\alpha_1 \alpha_2} |\alpha\rangle , \quad (2.9) \]

\[ |[3^-, 1]|^{ij} = \frac{1}{2} (\sigma^{ij})^{\alpha_1 \alpha_2} (\beta_n^{\dagger})_{\alpha_1 \alpha_2} (\beta_n^{\dagger})_{\alpha_1 \alpha_2} |\alpha\rangle , \quad (2.10) \]

\[ |[4, 4]|_{\pm}^{ij} = \frac{1 \pm \Omega}{2\sqrt{2}} (\sigma^{ij})^{\dagger \alpha_1 \alpha_2} (\sigma^{\alpha_1 \alpha_2})_{\alpha_1 \alpha_2} \alpha_1 \alpha_2 |\alpha\rangle , \quad (2.11) \]

\[ |[3^-, 3^-]|^{ij |i'j'|} = \frac{1}{2} (\sigma^{ij})^{\alpha_1 \alpha_2} (\sigma^{i'j'})^{\alpha_2 \alpha_2} (\beta_n^{\dagger})_{\alpha_1 \alpha_2} (\beta_n^{\dagger})_{\alpha_1 \alpha_2} |\alpha\rangle , \quad (2.12) \]

\(^2\)We will always suppress the $\delta$-function normalization factor $|\alpha_3|\delta(\alpha_3 + \alpha_4)$, where $\alpha_3$ and $\alpha_4$ denote the light-cone momenta of the in-/out-states, respectively.
and similarly for the remaining representations. Here, the singlets and $[|3^±, 3^±|]$ have odd, whereas the (anti)-selfdual representations have even worldsheet-parity. Again we have normalized the states to one. Notice that only $|[9, 1]|^{(ij)}$, $|[1, 9]|^{(i'j')}$ and $|[3^±, 3^±]|^{[ij][i'j']}$ are uniquely constructed of bosonic or fermionic oscillators, respectively.

The remaining representations are realized both with bosonic and fermionic oscillators and, therefore potentially mix with each other. For completeness we mention that fermionic two-impurity states transform as $[(2, 1), (1, 2)]$, $[(3, 2), (2, 1)]$, $[(2, 3), (1, 2)]$ and the same representations with the two $SO(4)'s$ exchanged. These are e.g.

$$=[[2, 1], (1, 2)]_{±1} = \frac{1 ± \Omega}{2} (\alpha_{±n})_{α_1α_2} (\beta_{ν}^{±})_{α_1α_2} |α⟩,$$  \hfill (2.13)

$$=[[2, 3], (1, 2)]_{±1} = \frac{1 ± \Omega}{2} (\sigma^{ij})^{α_1β_1} (\alpha_{±n})_{α_1α_2} (\beta_{ν}^{±})_{β_1α_2} |α⟩,$$  \hfill (2.14)

$$=[[3, 2], (2, 1)]_{±1} = \frac{1 ± \Omega}{2} (\sigma^{ij})^{α_1β_1} (\alpha_{±n})_{α_1α_2} (\beta_{ν}^{±})_{β_1α_2} |α⟩.$$  \hfill (2.15)

To construct the two-impurity multiplet explicitly we determine the highest weight state that is annihilated by $P^{I}$, $J^{I+}$, $Q^{+}$ and $\tilde{Q}^{+}$ (no zero-mode excitations), $J^{ij}$ and $J^{i'j'}$ (a singlet) and by half of the dynamical supercharges which we choose to be $\tilde{Q}_{α_1α_2}$ and $Q_{α_1α_2}$ (cf. Appendix A for their explicit oscillator expressions). The latter requirements impose three conditions on the most general ansatz (with $|A|^2 + |B|^2 + |C|^2 + |D|^2 = 1/4$ to normalize it to one)

$$|[1, 1]|_{(1)} = \left( A α_{±n}^{+i} α_{±n}^{+i} + B α_{±n}^{+i} α_{±n}^{+i} + C (β_{ν}^{±})_{α_1α_2} (β_{ν}^{±})_{α_1α_2} + D (β_{ν}^{±})_{α_1α_2} (β_{ν}^{±})_{α_1α_2} \right) |α⟩,$$  \hfill (2.16)

with the (up to a phase in $A$) unique solution

$$A = \frac{ω_ν - μα}{4ω_ν}, \quad B = \left( \frac{ω_ν + μα}{n} \right)^2 A, \quad C = -D = -ie(ω_ν + μα)nA.$$  \hfill (2.17)

As $|[1, 1]|_{(1)}$ contains states of opposite worldsheet parity, $Ω$ is not a quantum number to label states in the supermultiplet; in particular for large $μ$ and $α < 0$ we have

$$A ∼ \frac{1}{2}, \quad B ∼ -\frac{n^2}{8}λ', \quad C = -D ∼ \frac{in}{4}√nλ',$$  \hfill (2.18)

reflecting that in the BMN gauge theory the singlet operator built out of scalar impurities starts to mix with covariant derivatives and fermions at higher (than one) loops. By applying $Q_{α_1α_2}$ and $\tilde{Q}_{α_1α_2}$ successively to $|[1, 1]|_{(1)}$ we generate all $2^8 = 256$ states with two stringy excitations. For example, $[|3^±, 1]|_{i} = \frac{1}{2} (\sigma^{ij})^{α_1β_1} (α_{±n}^{i})_{α_1α_2} (β_{ν}^{±})_{β_1α_2} |α⟩$. 

\textsuperscript{3}In this case it is sometimes convenient to introduce $(α_{n}^{i})_{α_1α_2} ≡ \frac{1}{\sqrt{2}}(σ^{i})_{α_1α_2} α_{±n}^{i}$ and $(α_{±n}^{i})_{α_2α_2} ≡ \frac{1}{√2}(σ^{i})_{α_2α_2} α_{±n}^{i}$. Then e.g. $[|3^±, 1]|_{i} = \frac{1}{2} (σ^{ij})^{α_1β_1} (α_{±n}^{i})_{α_1α_2} (β_{ν}^{±})_{β_1α_2} |α⟩$. 

5
acting twice with $\sqrt{\mu} \delta \equiv e^{\alpha_1 \bar{\alpha}_2} Q_{\alpha_1 \alpha_2}^- + \bar{e}^{\bar{\alpha}_1 \alpha_2} Q_{\bar{\alpha}_1 \alpha_2}^-$ we find 4

$$
\delta^2 |[1,1]_{(1)}^\dagger = \frac{ie(n)}{\mu \alpha} \sqrt{\omega_n} (\omega_n + \mu \alpha) \left( e^{ij} |[3^-,1]_{(1)}^\dagger - \bar{e}^{ij} |[3^+,1]_{(1)}^\dagger \right) - \frac{\omega_n e^{ij} |[4,4]_{(1)}^\dagger}{\mu \alpha}.
$$

(2.19)

Here

$$
|[3^+,1]_{(1)}^\dagger = (\sigma^{ij})^{\alpha_1 \bar{\alpha}_1} \left( A_{(1/2)}(\alpha^+_n)_{\alpha_1 \bar{\alpha}_1} (\alpha^-_{-n})^{\alpha_1 \bar{\alpha}_1} + B_{(1/2)}(\beta^+_n)_{\bar{\alpha}_1 \alpha_1} (\beta^-_{-n})^{\bar{\alpha}_1 \alpha_1} \right) |\alpha\rangle,
$$

(2.20)

$$
|[3^-,1]_{(1)}^\dagger = (\sigma^{ij})^{\alpha_1 \bar{\alpha}_1} \left( A_{(1/2)}(\alpha^+_n)_{\alpha_1 \bar{\alpha}_1} (\alpha^-_{-n})^{\alpha_1 \bar{\alpha}_1} - B_{(1/2)}(\beta^+_n)_{\bar{\alpha}_1 \alpha_1} (\beta^-_{-n})^{\bar{\alpha}_1 \alpha_1} \right) |\alpha\rangle,
$$

(2.21)

$$
|[4,4]_{(1)}^\dagger = \frac{1 + \Omega}{4} (\sigma^{ij})^{\alpha_1 \bar{\alpha}_1} (\sigma^{ij})^{\bar{\alpha}_2 \alpha_2} \left( (\alpha^+_n)_{\alpha_1 \bar{\alpha}_1} (\alpha^-_{-n})^{\alpha_1 \bar{\alpha}_1} + e(\alpha)(\beta^+_n)_{\bar{\alpha}_1 \alpha_1} (\beta^-_{-n})^{\bar{\alpha}_1 \alpha_1} \right) |\alpha\rangle,
$$

(2.22)

and analogously for $(i,j) \rightarrow (i',j')$, while the mixing-coefficients are

$$
A_{(1/2)} = \sqrt{\frac{\omega_n + \mu \alpha}{8 \omega_n}}, \quad B_{(1/2)} = \pm i e(\alpha n) \sqrt{\frac{\omega_n + \mu \alpha}{8 \omega_n}}.
$$

(2.23)

In the large $\mu$ limit and $\alpha < 0$ this yields e.g. $A_1 \sim \frac{1}{2}, B_1 \sim \frac{i \mu}{2} \sqrt{\nu}$ so the mixing of states is again a $\sqrt{\nu}$ effect. For $|[4,4]_{(1)}^\dagger$ the mixing is maximal in agreement with the gauge theory result. Up to irrelevant phases and an overall factor of $\sqrt{2}$ (which can be absorbed in the definition of $e^{\alpha_1 \bar{\alpha}_2}, \bar{e}^{\bar{\alpha}_1 \alpha_2}$) the leading order SUSY variation (2.19) precisely agrees with [13].

### 3 Turning on Interactions

String interactions in the background have been treated within the framework of light-cone string field theory [4, 5, 6]. Its guiding principles are worldsheet continuity and the realization of the superalgebra in the full interacting theory: the superalgebra gives rise to two types of constraints – kinematical and dynamical – depending on whether the participating generators receive $g_2$ corrections ($H$, $Q^-$ and $\bar{Q}^-$) or not. Kinematical constraints lead to the continuity conditions in superspace, whereas dynamical constraints require the insertion of interaction point operators [29]. In practice these constraints will be solved perturbatively, for example $H$, the full Hamiltonian of the interacting theory, has an expansion in $g_2$

$$
H = H_2 + g_2 H_3 + g_2^2 H_4 + \cdots.
$$

(3.1)

Here the operator $H_3$ represents a three-string interaction, but it is more convenient to express it as a state $|H_3\rangle$ in the multi-string Hilbert space and work in the number basis [30]. Then the dynamical

---

4We define $e^{ij} = e_{\alpha_1 \bar{\alpha}_2} (\sigma^{ij})^{\alpha_1 \bar{\alpha}_1} e_{\alpha_1 \bar{\alpha}_1} = e_{\bar{\alpha}_2 \alpha_1} (\sigma^{ij})^{\bar{\alpha}_1 \alpha_1} e_{\bar{\alpha}_1 \alpha_1}$. Similarly, $e^{ij} = e_{\bar{\alpha}_1 \alpha_2} (\sigma^{ij})^{\bar{\alpha}_1 \bar{\alpha}_1} e_{\bar{\alpha}_1 \bar{\alpha}_1}$ and analogously for $e^{i'j'}$ etc.
generators are of the form $P|V\rangle$, where $P$ are the prefactors determined by the dynamical constraints (i.e. the oscillator expressions of the interaction point operators mentioned above) and the kinematical part of the vertex $|V\rangle$ common to all the dynamical generators implements the continuity conditions. These follow for example from $[H_3, P^{I}] = 0$, so the interaction vertex is translationally invariant and conserves transverse momentum. In the number basis the bosonic part of $O$ follows for example from $\left\{ H, Q \right\}$ and similar relations for $\tilde{Q}$.

In short, the three-string vertex and dynamical supercharges are known as Neumann matrices, see [31] for explicit expressions as functions of $\mu, \alpha_s$. To fulfil the dynamical constraints we define the linear combinations of the free supercharges $\sqrt{\alpha} \bar{Q} \equiv Q^- + i \bar{Q}^-$ and $\sqrt{\alpha} \bar{Q} \equiv Q^- - i \bar{Q}^-$ ($\eta = e^{i\pi/4}$) which satisfy on the space of physical states e.g.

$\{ Q_{\alpha_1 \dot{\alpha}_2}, \tilde{Q}_{\beta_1 \dot{\beta}_2} \} = \{ \bar{Q}_{\alpha_1 \dot{\alpha}_2}, \bar{Q}_{\beta_1 \dot{\beta}_2} \} = -2 \varepsilon_{\alpha_1 \dot{\alpha}_1} \varepsilon_{\dot{\alpha}_2 \dot{\beta}_2} H$,

$\{ Q_{\alpha_1 \dot{\alpha}_2}, \tilde{Q}_{\beta_1 \dot{\beta}_2} \} = -\mu \varepsilon_{\dot{\alpha}_2 \dot{\beta}_2}(\sigma^{ij})_{\alpha_1 \dot{\alpha}_1} J^{ij} + \mu \varepsilon_{\alpha_1 \dot{\alpha}_2}(\sigma^{ij})_{\dot{\alpha}_2 \dot{\beta}_2} J^{ij}$,

and similar expressions for $Q_{\dot{\alpha}_1 \alpha_2}$ and $\tilde{Q}_{\dot{\beta}_1 \beta_2}$. Since $J^{ij}$ and $J^{ij}$ are not corrected by the interaction, it follows that at order $O(g_2)$ the dynamical generators have to obey

$\{ Q_{\alpha_1 \dot{\alpha}_2}, Q_{\beta_1 \dot{\beta}_2} \} + \{ Q_{3 \alpha_1 \dot{\alpha}_2}, Q_{2 \beta_1 \dot{\beta}_2} \} = -2 \varepsilon_{\alpha_1 \dot{\alpha}_1} \varepsilon_{\dot{\alpha}_2 \dot{\beta}_2} H_3$,

$\{ Q_{\alpha_1 \dot{\alpha}_2}, \tilde{Q}_{\beta_1 \dot{\beta}_2} \} + \{ \tilde{Q}_{3 \alpha_1 \dot{\alpha}_2}, \tilde{Q}_{2 \beta_1 \dot{\beta}_2} \} = -2 \varepsilon_{\alpha_1 \dot{\alpha}_1} \varepsilon_{\dot{\alpha}_2 \dot{\beta}_2} H_3$,

$\{ Q_{\alpha_1 \dot{\alpha}_2}, \tilde{Q}_{\beta_1 \dot{\beta}_2} \} + \{ Q_{3 \alpha_1 \dot{\alpha}_2}, \tilde{Q}_{2 \beta_1 \dot{\beta}_2} \} = 0$.

Substituting the most general ansatz for, say $Q_{3 \alpha_1 \dot{\alpha}_2}$, compatible with the requirement that the Hamiltonian prefactor in its functional form is quadratic in derivatives, into (3.4) and demanding that the result only involves the tensor $\varepsilon_{\alpha_1 \dot{\alpha}_1} \varepsilon_{\dot{\alpha}_2 \dot{\beta}_2}$ fixes $Q_{3 \alpha_1 \dot{\alpha}_2}$ and consequently also $H_3$ up to their normalization. The same procedure applies to $\tilde{Q}_{3 \dot{\alpha}_1 \alpha_2}$ and requires that its normalization is the same as of $Q_{3 \alpha_1 \dot{\alpha}_2}$.

In short, the three-string vertex and dynamical supercharges are

$g_2 |H_3\rangle = -g_2 f(\mu \alpha_3, \frac{\alpha_1}{\alpha_3}) \frac{\kappa}{4 \alpha_3^3} \sum_{s=1}^{3} \sum_{m \in \mathbb{Z}} \frac{\omega_m}{\alpha_3} \alpha_{m(s)}^{1\dagger} \alpha_{m(s)}^{J} \frac{\alpha_3^{I\dagger} - \frac{\mu}{2} \delta_{IJ}}{2} V_{IJ} |V\rangle$,  

$g_2 |Q_{3 \beta_1 \dot{\beta}_2}\rangle = -g_2 \bar{\eta} f(\mu \alpha_3, \frac{\alpha_1}{\alpha_3}) \frac{1}{4 \alpha_3^3} \sqrt{-\frac{\alpha' \kappa}{2}} \bar{K} I q_{I \beta_1 \dot{\beta}_2} |V\rangle$,  

$g_2 |Q_{3 \dot{\beta}_1 \beta_2}\rangle = -g_2 \bar{\eta} f(\mu \alpha_3, \frac{\alpha_1}{\alpha_3}) \frac{1}{4 \alpha_3^3} \sqrt{-\frac{\alpha' \kappa}{2}} \bar{K} I q_{I \dot{\beta}_1 \beta_2} |V\rangle$,  

with similar expressions for $|\tilde{Q}_3\rangle$. Here $\kappa \equiv \alpha_1 \alpha_2 \alpha_3$, $\alpha_3 < 0$ for the incoming and $\alpha_1, \dot{\alpha}_2 > 0$ for the outgoing strings and $\bar{K} I$ is defined in (A.20). Further we list the relevant parts of $V_{IJ}$, $q_{I \beta_1 \dot{\beta}_2}$ and
$q_{\beta_1 \beta_2}$ in the next section, for complete expressions see e.g. [5]. In equations (3.7)-(3.9) we suppressed the integrals over light-cone momenta $\alpha_i$ and the $\delta$-function normalization factor $|\alpha_3 | \delta(\sum_{i=1}^{3} \alpha_i)$.

More importantly, as alluded to above, the normalization of the dynamical generators is not fixed by the superalgebra at order $O(g_2)$ and can be an arbitrary (dimensionless) function $f(\mu \alpha_3 , \frac{\alpha_2}{\alpha_3})$ of the light-cone momenta and $\mu$ due to the fact that $P^+$ is a central element of the algebra. Indeed, it does not seem that further consistency conditions at higher orders in $g_2$ would allow to fix $f$.

Now consider the constraints at order $O(g_2^2)$. These are e.g.

$$\{ Q_2 \dot{\alpha}_1 \dot{\alpha}_2, Q_4 \beta_1 \beta_2 \} + \{ Q_4 \dot{\alpha}_1 \dot{\alpha}_2, Q_2 \beta_1 \beta_2 \} + \{ Q_3 \dot{\alpha}_1 \dot{\alpha}_2, Q_3 \beta_1 \beta_2 \} = -2 \varepsilon_{\dot{\alpha}_1 \dot{\alpha}_2} \varepsilon_{\beta_1 \beta_2} H_4 ,$$

(3.10)

$$\{ \tilde{Q}_2 \dot{\alpha}_1 \dot{\alpha}_2, \tilde{Q}_4 \beta_1 \beta_2 \} + \{ \tilde{Q}_4 \dot{\alpha}_1 \dot{\alpha}_2, \tilde{Q}_2 \beta_1 \beta_2 \} + \{ \tilde{Q}_3 \dot{\alpha}_1 \dot{\alpha}_2, \tilde{Q}_3 \beta_1 \beta_2 \} = -2 \varepsilon_{\dot{\alpha}_1 \dot{\alpha}_2} \varepsilon_{\beta_1 \beta_2} H_4 ,$$

(3.11)

$$\{ \tilde{Q}_2 \dot{\alpha}_1 \dot{\alpha}_2, \tilde{Q}_4 \beta_1 \beta_2 \} + \{ \tilde{Q}_4 \dot{\alpha}_1 \dot{\alpha}_2, \tilde{Q}_2 \beta_1 \beta_2 \} + \{ Q_3 \dot{\alpha}_1 \dot{\alpha}_2, Q_3 \beta_1 \beta_2 \} = 0$$

(3.12)

and have been analyzed in some detail in [22]. In particular, it was found that $\{ Q_3 , Q_3 \}$ and $\{ Q_3 , \tilde{Q}_3 \}$ diverge in the $(2 \rightarrow 2)$-strings channel leading in the latter case to the introduction of a non-vanishing $Q_4$ (and $\tilde{Q}_4$). The new supercharges – together with $\{ Q_3 , Q_3 \}$ – generate a contact term $H_4$ needed for finite scattering amplitudes. An analogue argumentation presumably holds for the $(1 \rightarrow 1)$-string channel. We have checked that for our calculations the above conditions are not violated if $Q_4$ is set to zero. Still, this constitutes only a necessary but clearly not sufficient requirement.

## 4 Computing energy shifts in light-cone SFT

To compute the energy shift of two-impurity states to leading order in $g_2$, the relevant part of the Hamiltonian is

$$H = H_2 + g_2 H_3 + g_2^2 H_4 ,$$

(4.1)

where the contact term $H_4$ acting in the single-string Hilbert space is induced by the cubic super-charge

$$H_4 = \frac{1}{8} Q_3 \beta_1 \beta_2 Q_3^\beta_1 \beta_2 + \frac{1}{8} Q_3 \beta_1 \beta_2 Q_3^\beta_1 \beta_2 .$$

(4.2)

As we have seen in section 2 there are generically several two-impurity eigenstates transforming in the same irreducible representation of $SO(4) \times SO(4)$; hence these will mix with each other and we have to use degenerate perturbation theory to compute their energy shift. The required formula for the energy shift is standard and reads

$$\delta E^{(2)}_n (\varphi^A_n | 0) = g_2^2 \sum_B \left[ \sum_{p \neq n} \frac{\langle \varphi^A_n | H_3 | \psi^C_p \rangle \langle \psi^C_p | H_3 | \varphi^B_n \rangle}{E^{(0)}_n - E^{(0)}_p} + \langle \varphi^A_n | H_4 | \varphi^B_n \rangle \right] \langle \varphi^B_n | 0 \rangle ,$$

(4.3)

Here $A$ and $B$ label the degenerate one-string eigenstates, $\sum_C \sum_{p \neq n} \langle \varphi^C_p | \psi^C_p \rangle$ is the two-string projector and $| 0 \rangle = \sum_A \langle \varphi^A_n | 0 \rangle | \varphi^A_n \rangle$. Thus, we essentially have to diagonalize the mixing matrix

$$M^{AB} = \langle \varphi^A_n | H_3 (E^{(0)}_n - H_2) - 1 H_3 + H_4 | \varphi^B_n \rangle .$$

(4.4)

\(^{5}\)At this point we neglect possible contributions of $Q_4$. 

8
Since the theory is supersymmetric, this can be achieved by constructing supermultiplets: Suppose we have constructed the complete supermultiplet by acting with eight supercharges, say $Q_{\bar{\alpha}_1{\alpha}_2}$ and $Q^-_{\bar{\alpha}_1{\alpha}_2}$ on a highest weight state that is annihilated by the remaining charges. Now consider two states $|1\rangle$ and $|2\rangle$ carrying the same $SO(4) \times SO(4)$ quantum numbers, related by, say

$$|2\rangle = Q^{-4}|1\rangle, \quad Q^{-4} = Q^{-\alpha_1{\alpha}_2} Q^{-\dot{\beta}_1{\dot{\beta}}_2} = -(Q^{-})_{\alpha_1{\dot{\alpha}}_2} (Q^{-3})_{\alpha_1{\dot{\alpha}}_2}.$$  

Therefore we have to show that the off-diagonal matrix elements of $M^{AB}$ vanish

$$\langle 1| M | 2 \rangle = \langle 1| M Q^{-4} | 1 \rangle = \langle 1| \left( (Q^{-})_{\alpha_1{\dot{\alpha}}_2}, M \right) (Q^{-3})_{\alpha_1{\dot{\alpha}}_2} | 1 \rangle = 0,$$  

where we used that $\langle 1| Q^{-\alpha_1{\dot{\alpha}}_2} = 0$. As a matter of fact, equation (4.6) is a consequence of supersymmetry. Recall $[Q^{-}, H] = 0$, so in particular to order $g_2^2$ we have the conditions

$$[Q^{-}_2, H_2] = 0,$$  

$$[Q^{-}_2, H_3] = -[Q^{-}_3, H_2],$$  

Applying this to equation (4.6), using $\left\{ (Q^{-})_{\alpha_1{\dot{\alpha}}_2}, (Q^{-})_{\bar{\alpha}_1{\dot{\alpha}}_2} \right\} = 0$ and

$$\langle 1| H_3 \left( E_n^{(0)} - H_2 \right)^{-1} \left[ (Q^{-})_{\alpha_1{\dot{\alpha}}_2}, H_2 \right] (Q^{-3})_{\alpha_1{\dot{\alpha}}_2} | 1 \rangle = \langle 1| H_3 \left( Q^{-}_3 \right)_{\alpha_1{\dot{\alpha}}_2} (Q^{-3})_{\alpha_1{\dot{\alpha}}_2} | 1 \rangle,$$  

we find according to (4.10) and the Jacobi identity for $\left\{ [Q^{-}_1, H_2], (Q^{-3}_2) \right\}$, that

$$\langle 1| M | 2 \rangle = \langle 1| \left( (Q^{-})_{\alpha_1{\dot{\alpha}}_2}, H_3 \right) + \left[ (Q^{-}_2)_{\alpha_1{\dot{\alpha}}_2}, H_4 \right] \right) (Q^{-3})_{\alpha_1{\dot{\alpha}}_2} | 1 \rangle = 0.$$  

This proves the claim. We would like to stress that this proof is only valid when taking into account the full two-string projector, i.e. including impurity conserving and non-conserving channels. The same holds for the well-known statement that all states in a supermultiplet receive the same energy corrections.

In the following we will compute as an example the energy shift of the symmetric traceless state $[|9, 1\rangle^{(i)}]$. Due to the lack of adequate techniques we will restrict ourselves to the analysis of the impurity-conserving channel. Our result will further demonstrate the necessity of including the missing channels.

### 4.1 The energy shift of $[|9, 1\rangle^{(i)}]$  

As we saw in section 2 the state $[|9, 1\rangle^{(i)}]$ given in 2.7 has no counterpart built out of fermionic oscillators and thus, this case is comparatively easy to consider. The relevant expressions for the vertex are

$$v_{ij} = \delta_{ij}, \quad q'^{l}_{\dot{\gamma}_1{\dot{\gamma}}_2} = -i Z_{\dot{\gamma}_1{\dot{\gamma}}_2}(\sigma^{l})_{\dot{\beta}_1{\dot{\beta}}_2}, \quad q'^{l}_{\dot{\beta}_1{\dot{\beta}}_2} = -Y_{\dot{\gamma}_1{\dot{\gamma}}_2}(\sigma^{l})_{\dot{\beta}_1{\dot{\beta}}_2},$$  

$^{6}$ The same holds for the $[|3^\pm, 3^\mp\rangle]^{(i)}$ states on the “fermionic” side.
while the impurity-conserving part of the two-string projector \( \sum C \sum_{p \neq n} |\psi_p^C \rangle \langle \psi_p^C| \) reads\(^7\)

\[
1_{\text{2imp}}^{\text{loop}} = \int_0^1 \frac{dr}{2r(1-r)} \left[ \alpha_0^k |\tilde{\alpha}_1 \rangle \alpha_0^l |\tilde{\alpha}_2 \rangle |\tilde{\alpha}_1 \rangle |\tilde{\alpha}_2 \rangle \alpha_0^k + \sum_{p \in \mathbb{Z}} \alpha_p^k \alpha_{-p}^l |\tilde{\alpha}_1 \rangle |\tilde{\alpha}_2 \rangle \alpha_0^k \right],
\]

\[
1_{\text{2imp}}^{\text{cont}} = \int_0^1 \frac{dr}{r(1-r)} \left[ \alpha_0^k |\tilde{\alpha}_1 \rangle \beta_0^a |\tilde{\alpha}_2 \rangle |\tilde{\alpha}_1 \rangle \beta_0^a |\tilde{\alpha}_2 \rangle \alpha_0^k + \sum_{p \in \mathbb{Z}} \alpha_p^k \beta_{-p}^a |\tilde{\alpha}_1 \rangle |\tilde{\alpha}_2 \rangle \beta_0^a |\tilde{\alpha}_2 \rangle \alpha_0^k \right],
\]

(4.13)

where \( Y \) and \( Z \) denote the fermionic constituents of the prefactor (cf. (A.29)) and we sum over \( k, l \) and the \( \text{SO}(8) \) spinor index \( a \). Further we define \( \tilde{\alpha}_1 = -\alpha_3 r \) and \( \tilde{\alpha}_2 = -\alpha_3 (1-r) \) using already the \( \delta \)-function normalizations \( \alpha_0^k \delta(\tilde{\alpha}_1 + \tilde{\alpha}_2 + \alpha_3) = \alpha_0^k \delta(\tilde{\alpha}_1 + \tilde{\alpha}_2 + \alpha_3) = \alpha_0^k \delta(\alpha_3 + \alpha_4) \) from the two vertices; the factor \( |\alpha_3| \delta(\alpha_3 + \alpha_4) \) will be suppressed, as it is cancelled by the normalization of the external states.

In our notation, the oscillators act on the vacuum right next to them and therefore do not carry an extra index. This convention also circumvents potential double-countings, e.g. treating \( \alpha_0^l |p^+\rangle |p^+\rangle \) and \( \beta_0^a |p^+\rangle |p^+\rangle \) as different states although they both correspond to the large \( J \) limit of the field theory operator \( \text{Tr}[\phi_1 Z^{J/2}] \text{Tr}[Z^{J/2}] \).

When calculating the matrix elements of \( H_3 \) and \( Q_3 \), one obtains two contributions for each matrix element according to the two possibilities of contracting the vacua of \( 1_{\text{2imp}} \) with \( |\alpha_1 \rangle \) and \( |\alpha_2 \rangle \) of the vertex, meaning that \( \alpha_1 = -\alpha_3 r \) and \( \alpha_2 = -\alpha_3 (1-r) \) in the first and vice versa in the second term.

Both give the same result since the vertex is a symmetric function of the light-cone momenta. One finds

\[
(ij) \langle [9, 1] | \langle \tilde{\alpha}_2 | \alpha_0^l \langle \tilde{\alpha}_1 \rangle \alpha_0^k |H_3\rangle = - 2r(1-r) \left( \frac{\omega_n^{(3)}}{\alpha_3} + \mu \right) \tilde{N}_{n,0}^{31} \tilde{N}_{n,0}^{32} \Delta^{ijkl},
\]

(4.14)

\[
(ij) \langle [9, 1] | \langle \tilde{\alpha}_2 | \alpha_0^l \langle \tilde{\alpha}_1 \rangle \alpha_0^k |H_3\rangle = - 2r(1-r) \left( \frac{\omega_n^{(3)}}{\alpha_3} - \frac{\omega_n^{(1)}}{\alpha_3 r} \right) \tilde{N}_{n,p}^{31} \tilde{N}_{n,-p}^{31} \Delta^{ijkl}
\]

for the matrix elements of \( H_3 \) and

\[
(ij) \langle [9, 1] | \langle \tilde{\alpha}_2 | (\beta_0)^{\delta_1 \delta_2} \langle \tilde{\alpha}_1 \rangle \alpha_0^k |Q_3\rangle = - 2i \tilde{C} G_{0(2)} \left( K_n^{(3)} + K_n^{(3)} \right) \tilde{N}_{n,0}^{31} \Delta^{ijkl}(\sigma_1^{\delta_1} \sigma_2^{\delta_2}),
\]

\[
(ij) \langle [9, 1] | \langle \tilde{\alpha}_2 | (\beta_0)^{\delta_1 \delta_2} \alpha_0^k |Q_3\rangle = - 2i \tilde{C} G_{[1]} \left( K_n^{(3)} + K_n^{(3)} \right) \tilde{N}_{n,p}^{31} \Delta^{ijkl}(\sigma_1^{\delta_1} \delta_2^{\delta_2}),
\]

\[
(ij) \langle [9, 1] | \langle \tilde{\alpha}_2 | \delta_1^{\delta_2} \langle \tilde{\alpha}_1 \rangle \alpha_0^k |Q_3\rangle = - 2 \tilde{C} G_{0(2)} \left( K_n^{(3)} + K_n^{(3)} \right) \tilde{N}_{n,0}^{31} \Delta^{ijkl}(\sigma_1^{\delta_1} \delta_2^{\delta_2}),
\]

\[
(ij) \langle [9, 1] | \langle \tilde{\alpha}_2 | \delta_1^{\delta_2} \alpha_0^k |Q_3\rangle = - 2 \tilde{C} G_{[1]} \left( K_n^{(3)} + K_n^{(3)} \right) \tilde{N}_{n,p}^{31} \Delta^{ijkl}(\sigma_1^{\delta_1} \delta_2^{\delta_2}),
\]

(4.15)

for \( Q_3 \), where \( \Delta^{ijkl} \equiv \frac{1}{\sqrt{2}} \left\{ \delta^{ij} \delta^{kl} + \delta^{il} \delta^{jk} - \frac{1}{2} \delta^{ij} \delta^{kl} \right\} \) and \( \tilde{C} \equiv \frac{n}{4} \sqrt{\frac{\alpha_3}{2 \alpha_3}} \sqrt{r(1-r)} \). Here we have fixed the normalization function \( f = 1 \) such that the gauge theory matrix element \( \langle m; 1 - r | r | H | n; 1 \rangle \)

\(^7\)Note, for the same reason as described above, fermionic oscillators do not contribute in this case to \( 1_{\text{2imp}}^{\text{loop}} \).

\(^8\)The vectors \( K_n^{(t)} \) and \( G_n^{(t)} \) appear in the oscillator expansions of the bosonic/fermionic constituents \( K \), \( Y \) and \( Z \).
and $123\langle \alpha^1 \alpha^2 \alpha^3 | H_3 | \alpha^1 \alpha^2 \alpha^3 \rangle$ agree at leading order. It should be mentioned, that regardless of the form of $f$ the matrix elements necessarily fail to match at higher order [27]. Thus, this choice seems to be somewhat arbitrary. Moreover, the final result for the energy shift might be very sensitive to the $r$-dependence of $f$ due to the integral in the projector.

After plugging in all remaining expressions (cf. Appendix A) the complete result - up to exponential corrections - for the $|9,1\rangle^{ij}$ state reads

$$\frac{1}{\mu} \delta E^{(2)}_n \approx g^2 \int_0^1 \frac{\sin^4(\pi nr)}{8 \pi^4 \omega_{n(3)}^2} \left\{ \frac{n^2 + 4 \mu \alpha_3 (\mu \alpha_3 - \omega_{n(3)})}{2 r n^2 \mu^2 \alpha_3^2} - \frac{r^2 (1-r)}{\mu \alpha_3} \sum_{\rho > 0} \frac{n^2 \omega_\rho (1) - 2 \mu^2 \alpha_3^2 (\omega_\rho (1) - r \omega_{n(3)})}{\omega_\rho^2 (1) (\omega_\rho (1) - r \omega_{n(3)})^2} \right\}$$

$$= g^2 \int_0^1 \frac{\sin^4(\pi nr)}{16 \pi^4 \omega_{n(3)}^2 \mu^2 \alpha_3} \left\{ \left[ n^2 (1 - 2 (1-r) \mu \alpha_3) + 4 \mu \alpha_3 (\mu \alpha_3 - \omega_{n(3)}) \right] \omega_{n(3)} - 2 n (1-r) \mu \alpha_3 \left[ (2 \mu^2 \alpha_3^2 + \omega_{n(3)}^2) (\text{arccsch} (\frac{\mu \alpha_3}{n}) + \pi \cot (\pi nr)) + n \pi^2 r \omega_{n(3)}^2 \text{csc}^2 (\pi nr) \right] \right\}$$

(4.16)

where we have cancelled the normalization factor $1 + \frac{1}{2} \delta^{ij}$ on both sides and the sum is computed in Appendix B. Performing the integral one finds

$$\frac{1}{\mu} \delta E^{(2)}_n \approx \frac{g^2}{768 \pi^4 n^2 \omega_{n(3)}^3 \mu^2 \alpha_3} \left\{ n^2 \left( 18 \omega_{n(3)} - \mu \alpha_3 (9 + 2 \omega_{n(3)} (9 + 4 \pi^2 \omega_{n(3)})) \right) - 3 \mu \alpha_3 (9 \mu^2 \omega_{n(3)}^2 - 24 \omega_{n(3)}\mu \alpha_3 + 32 \omega_{n(3)}^2) \right\} \text{arccsch} \left( \frac{\mu \alpha_3}{n} \right)$$

$$= \frac{g^2}{4 \pi^2} \left\{ \left( \frac{1}{24} + \frac{65}{64 n^2 \pi^2} \right) \lambda - \frac{3}{16 \pi^2} \lambda^{3/2} - \frac{n^2}{2} \left( \frac{1}{24} + \frac{89}{64 n^2 \pi^2} \right) \lambda^2 + \frac{9 n^2}{32 \pi^2} \lambda^{5/2} + \cdots \right\}.$$

(4.17)

This result leads to several interesting observations, which we will discuss in what follows: First of all, the leading order contribution in $\lambda'$ does not match the anomalous dimension computed in field theory (see [12, 21]) and also disagrees with the original computation of [14]. The latter mismatch can be traced back to a reflection-symmetry factor $\frac{1}{2}$ introduced in equation (3.3) of [13]. Since the formula for the energy shift in equation (4.3) is standard quantum mechanical perturbation theory, such a factor cannot be justified. Further we have been careful to define the two-string projectors – concerning accidental over-counting – and therefore we are confident that our result is correct.

Even more, when repeating the analogous calculation for the states $|3^\pm,1\rangle^{ij}$, one does not obtain the result given in [14] already at leading order in $\lambda'$. This computation coincides – up to a factor of $\frac{1}{2}$ – with that of the representation 6 done in [13]11, because the mixing with states consisting of

\footnote{Note, that we have used $(\Delta^{ij})^2 = 1 + \frac{1}{2} \delta^{ij}$ and $|\Delta^{ij} (\sigma')^3 |^2 = 2 (1 + \frac{1}{2} \delta^{ij})$.}

\footnote{It should be mentioned, that it is not consistent to take $\mu$ to infinity before computing the sum as this leads to divergent series.}

\footnote{Here only the contact term contributes and thus, the reflection-symmetry factor has no effect. The mismatch by $\frac{1}{2}$ is due to the different definition of the projectors (no sums over $r = 1, 2$), cf. the discussion below [14].}
fermionic oscillators starts to effect the energy shift at order $\lambda^2$. Since both representations are in the same multiplet (cf. section 2) and therefore are guaranteed to receive the same energy shift, this fact clearly shows, that it is not sufficient to restrict oneself only to the impurity-conserving channel. Moreover, additional contributions of a $Q_4$-induced contact term cannot be ruled out so far. For $\lambda^2$ the discrepancies increase. Now, not only the coefficients, but also the $n$-dependence do not reproduce the field theory result [9].

A new interesting aspect is the appearance of half-integer powers of $\lambda'$. These obviously do not have a counterpart in perturbative, non-planar SYM. The existence of half-integer powers in the expansion of Neumann matrix elements have already been noticed in [33], but to our knowledge this constitutes the first example of their appearance in a physical quantity. Although these might be an artefact of the truncation to the impurity-conserving channel, we expect them to be a generic feature of the complete SFT result representing a qualitative difference to the planar sector.

In general one can say, that light-cone SFT is not sufficiently developed yet to give an unambiguous test of the non-planar part of the BMN correspondence. Apart from the presence of $Q_4$, which remains to be clarified, this mainly concerns the issue of normalization functions of the vertices not being fixed by the superalgebra. It would desirable to find a SYM independent method to determine these.

### Acknowledgements

We are grateful to G. Arutyunov, N. Beisert, J. Plefka, M. Staudacher and B. Stefaniński jr. for useful discussions. AP acknowledges support by the DOE under contract DE-FGO2-96ER40956. AP and PG thank the Albert-Einstein Institute and the University of Washington respectively, for hospitality during the course of this project.

### A Notations and Definitions

In this Appendix we collect our conventions and definitions as well as some useful identities. Compared to [4] we performed the following redefinitions of our oscillator basis for $n > 0$ to have the standard level-matching condition

\begin{align}
\sqrt{2}a^i_n & \equiv \alpha^i_n + \alpha^i_{-n}, & i\sqrt{2}a^i_{-n} & \equiv \alpha^i_n - \alpha^i_{-n}, & a^i_0 & \equiv \alpha^i_0, \\
\sqrt{2}a'^i_n & \equiv \alpha'^i_n + \alpha'^i_{-n}, & i\sqrt{2}a'^i_{-n} & \equiv \alpha'^i_n - \alpha'^i_{-n}, & a'^i_0 & \equiv \alpha'^i_0, \\
\sqrt{2}b^{\alpha_1\alpha_2}_n & \equiv \beta^{\alpha_1\alpha_2}_n + \beta^{\alpha_1\alpha_2}_{-n}, & i\sqrt{2}b^{\alpha_1\alpha_2}_{-n} & \equiv \beta^{\alpha_1\alpha_2}_n - \beta^{\alpha_1\alpha_2}_{-n}, & b^{\alpha_1\alpha_2}_0 & \equiv \beta^{\alpha_1\alpha_2}_0, \\
i\sqrt{2}b^{\dot{\alpha}_1\dot{\alpha}_2}_n & \equiv -\beta^{\dot{\alpha}_1\dot{\alpha}_2}_n + \beta^{\dot{\alpha}_1\dot{\alpha}_2}_{-n}, & \sqrt{2}b^{\dot{\alpha}_1\dot{\alpha}_2}_{-n} & \equiv \beta^{\dot{\alpha}_1\dot{\alpha}_2}_n + \beta^{\dot{\alpha}_1\dot{\alpha}_2}_{-n}, & b^{\dot{\alpha}_1\dot{\alpha}_2}_0 & \equiv \beta^{\dot{\alpha}_1\dot{\alpha}_2}_0. 
\end{align}
The oscillators obey the standard commutation relations\(^\text{12}\)

\[
[a^i_m, a^j_n] = \delta_{mn} \delta^{ij}, \quad \{(\beta^i_m)_{\alpha_1\alpha_2}, (\beta^j_n)_{\beta_1\beta_2}\} = \delta_{mn} \delta^{i_1}_{\alpha_1} \delta^{j_2}_{\alpha_2}. \tag{A.5}
\]

It is convenient to introduce

\[
(\alpha^\dagger_m)_{\alpha_1\alpha_1} \equiv \frac{1}{\sqrt{2}} (\sigma^i)_{\alpha_1\alpha_1} a^i_m, \quad (\alpha^\dagger_n)_{\alpha_2\alpha_2} \equiv \frac{1}{\sqrt{2}} (\sigma^i)_{\alpha_2\alpha_2} a^i_n \tag{A.6}
\]

which satisfy

\[
[(\alpha^\dagger_m)_{\alpha_1\alpha_1}, (\alpha^\dagger_n)_{\beta_1\beta_1}] = \delta_{mn} \delta^{i_1}_{\alpha_1} \delta^{j_2}_{\beta_1}, \quad [(\alpha^\dagger_m)_{\alpha_2\alpha_2}, (\alpha^\dagger_n)_{\beta_2\beta_2}] = \delta_{mn} \delta^{i_2}_{\alpha_2} \delta^{j_2}_{\beta_2}. \tag{A.7}
\]

The \(\sigma\) matrices consist of the usual Pauli-matrices together with the 2d unit matrix (spinorial indices are raised and lowered with \(\varepsilon_{\alpha\beta} = \varepsilon_{\hat{\alpha}\hat{\beta}} \equiv (\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix})\)) \(\sigma^{i}_{\alpha\alpha} = (i\tau^1, i\tau^2, i\tau^3, -1)_{\alpha\alpha}\). Notice the reality properties \([\sigma^i_{\alpha\alpha}]^\dagger = \sigma^\dagger_{\hat{\alpha}\hat{\alpha}}, [\sigma^i_{\hat{\alpha}\hat{\alpha}}]^\dagger = -\sigma^\dagger_{\alpha\alpha}\) which are consistent with the above commutation relations. Some useful identities are

\[
\varepsilon_{\alpha\beta} \varepsilon^{\gamma\delta} = \delta^\gamma_\alpha \delta^\delta_\beta - \delta^\gamma_\beta \delta^\delta_\alpha, \tag{A.8}
\]

\[
\varepsilon_{\alpha\beta} \sigma^{ij}_{\alpha\beta} = \delta^{ij}_{\alpha\beta} - \delta^{ij}_{\beta\alpha}, \quad \sigma^{ij}_{\alpha\beta} \equiv \sigma^{[ij]}_{\alpha\alpha} = \sigma^{[ij]}_{\beta\beta}, \tag{A.9}
\]

\[
\sigma^{ij}_{\alpha\alpha} \sigma^{ij}_{\beta\beta} = -\delta^{ij}_{\alpha\beta} + \delta^{ij}_{\beta\alpha}, \quad \sigma^{ij}_{\alpha\beta} \equiv \sigma^{[ij]}_{\alpha\alpha} = \sigma^{[ij]}_{\beta\beta}, \tag{A.10}
\]

\[
\sigma^{ij}_{\alpha\alpha} \sigma^{ij}_{\beta\beta} = 2 \varepsilon_{\alpha\beta} \varepsilon^{ij}_{\alpha\alpha}, \tag{A.11}
\]

\[
\frac{1}{2} \varepsilon^{ijkl} \sigma^{kl}_{\alpha\alpha} = -\sigma^{ij}_{\alpha\beta}, \tag{A.12}
\]

\[
\frac{1}{2} \varepsilon^{ijkl} \sigma^{kl}_{\hat{\beta}\hat{\alpha}} = \sigma^{ij}_{\hat{\alpha}\hat{\beta}}. \tag{A.13}
\]

The free dynamical supercharges are

\[
\sqrt{\frac{\mu}{2}} Q^{-\alpha_1\alpha_2} = -\frac{\sqrt{\mu}\alpha}{2\sqrt{2}} (1 - e(\alpha)) \left[ a^\dagger_{0\alpha_1} \beta^\dagger_{0\beta_1\beta_2} + a^\dagger_{0\alpha_2} \beta^\dagger_{0\alpha_1\beta_2} \right]
\]

\[
+ \sum_{k \neq 0} \left[ \sqrt{\omega_k + \mu \alpha} a^\dagger_{k\alpha_1} \beta^\dagger_{k\beta_1\alpha_2} - i e(\alpha k) \sqrt{\omega_k - \mu \alpha} a^\dagger_{k\alpha_1} \beta^\dagger_{k\beta_1\alpha_2} \right)
\]

\[
\times e(\alpha) \left( \sqrt{\omega_k + \mu \alpha} a^\dagger_{k\alpha_1} \beta^\dagger_{k\beta_1\alpha_2} - i e(\alpha k) \sqrt{\omega_k - \mu \alpha} a^\dagger_{k\alpha_1} \beta^\dagger_{k\beta_1\alpha_2} \right), \tag{A.14}
\]

\[
\sqrt{\frac{\mu}{2}} Q^{-\alpha_1\alpha_2} = \frac{\sqrt{\mu}\alpha}{2\sqrt{2}} (1 + e(\alpha)) \left[ a^\dagger_{0\alpha_1} \beta^\dagger_{0\beta_1\beta_2} + a^\dagger_{0\alpha_2} \beta^\dagger_{0\alpha_1\beta_2} \right]
\]

\[
+ \sum_{k \neq 0} \left[ \sqrt{\omega_k + \mu \alpha} a^\dagger_{k\alpha_1} \beta^\dagger_{k\beta_1\alpha_2} - i e(\alpha k) \sqrt{\omega_k - \mu \alpha} a^\dagger_{k\alpha_1} \beta^\dagger_{k\beta_1\alpha_2} \right)
\]

\[
\times e(\alpha) \left( \sqrt{\omega_k + \mu \alpha} a^\dagger_{k\alpha_1} \beta^\dagger_{k\beta_1\alpha_2} - i e(\alpha k) \sqrt{\omega_k - \mu \alpha} a^\dagger_{k\alpha_1} \beta^\dagger_{k\beta_1\alpha_2} \right). \tag{A.15}
\]

\(^{12}\)Note that e.g. \([\beta^\dagger_{0\alpha_1}] = -\beta^\dagger_{0\alpha_1}.\)
\( Q^- = e(\alpha) [Q^-]^\dagger \). 

Now we present the quantities appearing in the vertex; namely Neumann matrices, bosonic and fermionic prefactors and all related functions. Note, that for simplicity will already set \( \beta_1 \equiv r \) and \( \beta_2 \equiv 1 - r \) (with \( \beta_i \equiv -\alpha_i/\alpha_3 \) and \( \alpha_3 < 0 \)) in some of the expressions. The Neumann matrices appearing in the bosonic vertex read

\[
\bar{N}^{st}_{mn} = \begin{cases} 
\frac{1}{2} N^{st}_{|m||n|} (1 + U_{m(s)} U_{n(t)}) & , m, n \neq 0 \\
\frac{1}{\sqrt{2}} N^{st}_{|m|0} & , m \neq 0 \\
N^{st}_{00} & 
\end{cases}
\]

(A.16)

with\(^{13}\)

\[
\bar{N}^{st}_{mn} = -(1 - 4 \mu K)^{-1} \frac{\kappa}{\alpha_s \omega_n(t) + \alpha_t \omega_m(s)} \left[ C U_{(s)}^{-1} C_{(s)}^{1/2} \bar{N}^s_{m} \right] \left[ C U_{(t)}^{-1} C_{(t)}^{1/2} \bar{N}^t_{n} \right] ,
\]

(A.17)

\[
\bar{N}^{st}_{mb} = \sqrt{-2 \mu K (1 - \beta_t)} \sqrt{\omega_n(s)} \bar{N}^s_{m} ,
\]

(A.18)

\[
\bar{N}^{st}_{0b} = (1 - 4 \mu K) \left( \delta^{st} - \sqrt{\beta_s \beta_t} \right) ,
\]

(A.19)

\[
\bar{N}^{st}_{0s} = -\sqrt{\beta_s} ,
\]

(A.20)

Here we have used the short cuts

\[
C_n = n , \quad C_{n(s)} = \omega_n(s) \equiv \sqrt{n^2 + (\mu \alpha_s)^2} , \quad \kappa \equiv \alpha_1 \alpha_2 \alpha_3 ,
\]

(A.21)

\[
U_{n(s)} = \frac{1}{n} (\omega_n(s) - \mu \alpha_s) , \quad U_{n(s)}^{-1} = \frac{1}{n} (\omega_n(s) + \mu \alpha_s) .
\]

(A.22)

Neglecting exponential corrections \( \sim O(e^{-\mu \alpha_3}) \) the exact \( \mu \) dependence of the Neumann vectors \( \bar{N}^s \) and scalar \( K \) is \(^{14}\)

\[
1 - 4 \mu K \approx - \frac{1}{4 \pi r (1 - r) \mu \alpha_3} ,
\]

(A.23)

\[
\alpha_3 \bar{N}^3_n \approx - \frac{\sin(n \pi r)}{\pi r (1 - r) \omega_n(3) \sqrt{-2 \mu \alpha_3 (\omega_n(3) + \mu \alpha_3)}} ,
\]

(A.24)

\[
\alpha_3 \bar{N}^s_n \equiv \alpha_3 \bar{N}_n(\beta_s) \approx - \frac{\sqrt{\beta_s}}{2 \pi r (1 - r) \omega_n(\beta_s) \sqrt{-2 \mu \alpha_3 (\omega_n(\beta_s) - \mu \alpha_3 \beta_s)}} .
\]

(A.25)

The bosonic constituents of the prefactor are defined as

\[
K^I = \sum_{s=1}^{3} \sum_{n \in \mathbb{Z}} K_{n(s)} \alpha^{I}_{n(s)} , \quad \bar{K}^I = \sum_{s=1}^{3} \sum_{n \in \mathbb{Z}} K_{n(s)}^{\dagger} \alpha^{I \dagger}_{n(s)} ,
\]

(A.26)

\(^{13}\)To have a manifest symmetry in 1 \( \leftrightarrow \) 2 we additionally redefined the oscillators as \( (-1)^{s(n+1)} \alpha_{n(s)} \rightarrow \alpha_{n(s)} \) for \( n \in \mathbb{Z} , \)

\(^{14}\)To compare with the definition used in \(^{31}\) note that \( \bar{N}_{n, \text{here}} = (-1)^{s(n+1)} U_{n(s)} C_{n(s)}^{1/2} \bar{N}^s_n \).
with \((n \neq 0)\)

\[
K_{0(s)} = (1 - 4\mu K K)^{1/2} \sqrt{-\frac{2\mu K}{\alpha^2} (1 - \beta_s)} , \quad K_{0(3)} = 0 , \tag{A.27}
\]

\[
K_{n(s)} = -\frac{\kappa}{\sqrt{2\alpha^2 \alpha_s}} (1 - 4\mu K K)^{-1/2} (\bar{\omega}_n(s) + \mu \alpha_s) \sqrt{\bar{\omega}_n(s) \bar{\tilde{N}}_{[n]}^*} (1 - U_n(s)) , \tag{A.28}
\]

while the fermionic constituents of the prefactor are

\[
Y^{\alpha_1 \alpha_2} = 3 \sum_{s=1}^{3} \sum_{n \in \mathbb{Z}} G_{[n](s)} \beta_{\alpha_1 \alpha_2}^{\dagger} n_{(s)} , \quad Z^{\hat{\alpha}_1 \hat{\alpha}_2} = 3 \sum_{s=1}^{3} \sum_{n \in \mathbb{Z}} G_{[n](s)} \beta_{\alpha_1 \alpha_2}^{\dagger} \hat{n}_{[s]} , \tag{A.29}
\]

with \((n \neq 0)\)

\[
G_{0(s)} = (1 - 4\mu K K)^{1/2} \sqrt{1 - \beta_s} , \quad G_{0(3)} = 0 , \tag{A.30}
\]

\[
G_{n(s)} = \frac{e(\alpha_s)}{\sqrt{2|\alpha_s|} (1 - 4\mu K K)^{1/2}} \sqrt{\bar{\omega}_n(s) + \mu \alpha_s} \bar{\omega}_n(s) \bar{\tilde{N}}_{[n]}^* . \tag{A.31}
\]

**B Sums**

The sum over \(p\) in equation \((4.16)\) splits up into two parts, namely

\[
\sum_{p>0} \left\{ \frac{n^2}{\omega_{p(1)} (\omega_{p(1)} - r \omega_{n(3)})^2} - 2\mu^2 \alpha_3^2 \frac{1}{\omega_{p(1)} (\omega_{p(1)} - r \omega_{n(3)})} \right\} := n^2 S(\mu) - 2\mu^2 \alpha_3^2 T(\mu) . \tag{B.1}
\]

In the remainder of this section we will use \(a \equiv -\mu \alpha_3 r\) and \(b \equiv r \omega_{n(3)}\). Note, that \(b > a \geq 0\).

For the computation of \(S(\mu)\) we use the following trick

\[
\sum_{p>0} \frac{1}{\sqrt{p^2 + a^2 (\sqrt{p^2 + a^2} - b)^2}} = \frac{d}{db} \sum_{p>0} \frac{\sqrt{p^2 + a^2} + b}{\sqrt{p^2 + a^2 (p^2 - b^2 + a^2)}} = \frac{d}{db} \sum_{p>0} \left[ \frac{1}{p^2 - b^2 + a^2} + \frac{b}{\sqrt{p^2 + a^2 (p^2 - b^2 + a^2)}} \right] , \tag{B.2}
\]

where we have integrated over \(b\) and expanded with \(\sqrt{p^2 + a^2} + b\). The first part gives

\[
\sum_{p>0} \frac{1}{p^2 - b^2 + a^2} = \frac{1 - \sqrt{b^2 - a^2} \pi \cot(\sqrt{b^2 - a^2} \pi)}{2(b^2 - a^2)} , \tag{B.3}
\]

while the second can be represented as (using the contour integral method, see e.g. \[31\])

\[
\sum_{p>0} \frac{b}{\sqrt{p^2 + a^2 (p^2 - b^2 + a^2)}} = \frac{b}{2a(b^2 - a^2)} - \frac{\pi \cot(\sqrt{b^2 - a^2} \pi)}{\sqrt{b^2 - a^2}} + b \int_{1}^{\infty} \frac{dx \cot(a \pi x)}{(a^2 x^2 + b^2 - a^2) \sqrt{x^2 - 1}} . \tag{B.4}
\]
We rewrite the integral as
\[
\int_1^\infty \frac{dx \coth(a\pi x)}{(a^2 x^2 + b^2 - a^2) \sqrt{x^2 - 1}} = \int_1^\infty dx \left[ \frac{1}{(a^2 x^2 + b^2 - a^2) \sqrt{x^2 - 1}} - \frac{2}{a^2 (x^2 + \frac{b^2}{a^2} - 1) \sqrt{x^2 - 1} (1 - e^{2a\pi x})} \right] \approx \text{arccsch} \left( \frac{a}{b\sqrt{b^2 - a^2}} \right),
\]
(B.5)
where we utilized that for large \(a, \frac{b^2}{a^2}\) finite, the second integral can be omitted, thereby again neglecting exponential corrections. \text{arccsch}(x) is the inverse hyperbolic cosecans function. Hence we find
\[
\sum_{p > 0} \frac{1}{\sqrt{p^2 + a^2} (\sqrt{p^2 + a^2} - b)^2} \approx \frac{d}{db} \left[ \frac{1}{2a(b - a)} - \frac{\pi \cot(\sqrt{b^2 - a^2} \pi)}{\sqrt{b^2 - a^2}} + \text{arccsch} \left( \frac{a}{\sqrt{b^2 - a^2}} \right) \right]
\]
\[
= -\frac{1}{2a(b - a)^2} + \frac{1}{b^2 - a^2} + \frac{b}{(b^2 - a^2)^{3/2}} \left[ -\text{arccsch} \left( \frac{a}{\sqrt{b^2 - a^2}} \right) \right]
\]
\[
+ \pi \cot(\sqrt{b^2 - a^2} \pi) + \pi^2 \sqrt{b^2 - a^2} \csc^2(\sqrt{b^2 - a^2} \pi) .
\]
(B.6)
Now we turn to the sum \(T(\mu)\). It takes the form
\[
\sum_{p > 0} \frac{1}{(p^2 + a^2)(\sqrt{p^2 + a^2} - b)} = \sum_{p > 0} \left[ \frac{1}{\sqrt{p^2 + a^2} (p^2 - b^2 + a^2)} + \frac{b}{(p^2 + a^2)(p^2 - b^2 + a^2)} \right],
\]
(B.7)
where the first part was already computed in equation (B.4). The remaining sum yields
\[
\sum_{p > 0} \frac{1}{\sqrt{p^2 + a^2} (p^2 - b^2 + a^2)} = \frac{1}{2a^2(b^2 - a^2)} - \frac{\pi \cot(\sqrt{b^2 - a^2} \pi)}{2b^2 \sqrt{b^2 - a^2}} - \frac{\pi}{2ab^2} \coth(\pi a),
\]
(B.8)
and therefore up to exponential corrections one finds
\[
\sum_{p > 0} \frac{1}{(p^2 + a^2)(\sqrt{p^2 + a^2} - b)} \approx \frac{1}{2a^2(b - a)} - \frac{\pi \cot(\sqrt{b^2 - a^2} \pi)}{b \sqrt{b^2 - a^2}} + \text{arccsch} \left( \frac{a}{b\sqrt{b^2 - a^2}} \right).
\]
(B.9)
