Abstract

We use the stability conditions of the Landau parameters for the symmetric nuclear matter and pure neutron matter to calculate the critical densities for the Skyrme type effective nucleon-nucleon interactions. We find that the critical density can be maximized by adjusting appropriately the values of the enhancement factor $\kappa$ associated with isovector giant dipole resonance, the quantity $L$ which is directly related to the slope of the symmetry energy and the Landau parameter $G'_0$. However, restricting $\kappa$, $L$ and $G'_0$ to vary within acceptable limits reduces the maximum value for the critical density $\tilde{\rho}_{cr}$ by $\sim 25\%$. We also show that among the various quantities characterizing the symmetric nuclear matter, $\tilde{\rho}_{cr}$ depends strongly on the isoscalar effective mass $m^*/m$ and surface energy coefficient $E_s$. For realistic values of $m^*/m$ and $E_s$ we get $\tilde{\rho}_{cr} = 2\rho_0$ to $3\rho_0$ ($\rho_0 = 0.16\text{fm}^{-3}$).

There are many different parameterizations of the Skyrme type effective nucleon-nucleon interaction as recently reviewed in Ref. [1]. Values of the Skyrme parameters are usually obtained by fitting the results of the Hartree-Fock calculations for the binding energies, charge radii and spin-orbit splittings of a few closed shell nuclei to the observed ones using a least square procedure. The Skyrme parameters are also constrained to yield appropriate values for some properties of the infinite symmetric nuclear matter at the saturation density \( \rho_{\text{nm}} \). Over time, several improvements were made by appropriately treating the center of mass correction to the binding energy, modifying the spin-orbit part of the interaction and including in the least square fit the equation of state (EOS) for the pure neutron matter obtained from a realistic interaction [2, 3]. Nevertheless, not all the Skyrme parameters are well determined in this way.

Recently, it has been shown in Ref. [4] that a more realistic parameterization of the Skyrme interaction can be obtained by subjecting it to stability requirements of the EOS defined by the inequality conditions for the Landau parameters for symmetric nuclear matter and pure neutron matter. In other words, few of the Skyrme parameters not well determined by the experimental data used in the least square procedure can be restricted by requiring that the inequality conditions are satisfied up to a maximum value for a nuclear matter density, also referred to as the critical density \( \rho_{\text{cr}} \). A very recent systematic study carried out in Ref. [5] using several Skyrme interactions indicates that the density dependence of the symmetry energy coefficient \( J \) plays a critical role in determining the properties of neutron star. Out of 87 different parameterizations for the Skyrme interaction considered in Ref. [5] only 27 of them, having a positive slope for the symmetry energy coefficient at nuclear matter densities \( \rho \) up to \( 3\rho_0 \) (\( \rho_0 = 0.16\text{fm}^{-3} \)), are found to be suitable for the neutron star model. Thus, it appears that the parameters of the Skyrme interactions can be better constrained by combining the findings of Refs. [4] and [5].

In the present work we study the dependence of \( \rho_{\text{cr}} \) on the nuclear matter saturation density \( \rho_{\text{nm}} \), binding energy per nucleon \( B/A \), isoscalar effective mass \( m^*/m \), incompressibility coefficient \( K_{\text{nm}} \), surface energy \( E_s \), and symmetry energy coefficient \( J \), as also considered in Ref. [4]. It must be emphasized that we determine \( \rho_{\text{cr}} \) in terms of the enhancement factor \( \kappa \), the coefficient \( L = 3\rho dJ/d\rho \) and the Landau parameter \( G'_0 \) (at \( \rho_{\text{nm}} \)) instead of the combinations \( t_iz_i \) (\( i = 1, 2, \) and 3) of the Skyrme parameters \( t_i \) and \( x_i \) as used in Ref. [4]. Unlike the combinations \( t_iz_i \), the quantities \( \kappa \), \( L \) and \( G'_0 \), which can be expressed in terms
of the Skyrme parameters, are related to some physical processes. The enhancement factor \( \kappa \) accounts for the deviations from the Thomas-Reiche-Kuhn (TRK) sum rule in the case of the isovector giant dipole resonance. The value of \( \kappa \) at the \( \rho_{nm} \) is expected to be \( \sim 0.5 \)\(^2\). The slope of the symmetry energy coefficient must be positive for \( \rho \) up to \( 3\rho_0 \), so that resulting Skyrme interaction can be suitable for the study of the properties of neutron stars\(^3\). The Landau parameter \( G'_0 \) must be positive at \( \rho \leq \rho_{nm} \) in order to appropriately describe the position of the isovector \( M1 \) and Gamow-Teller states\(^4\). We find that by restricting the values of \( \kappa \), \( L \) and \( G'_0 \) within the acceptable limits, the maximum critical densities are lowered by about 25\% compared to the ones obtained without such restrictions\(^4\). The constrains proposed in the present work not only maximizes the value of the critical density, but also ensures that the resulting Skyrme interaction can be used to study the bulk properties of finite nuclei as well as those of neutron stars.

Recently\(^1,7\) a generalized form for the Skyrme energy density functional has been obtained using the Hohenberg-Kohn-Sham approach. However, in the present work we restrict ourselves to the energy density functional associated with the commonly used Skyrme interaction\(^2,8\),

\[
V_{12} = t_0 (1 + x_0 P_{12}^\sigma) \delta(r_1 - r_2) \\
\quad + \frac{1}{2} t_1 (1 + x_1 P_{12}^\sigma) \times \left[ k_{12}^2 \delta(r_1 - r_2) + \delta(r_1 - r_2) k_{12}^2 \right] \\
\quad + t_2 (1 + x_2 P_{12}^\sigma) \overrightarrow{k}_{12} \delta(r_1 - r_2) \overrightarrow{k}_{12} \\
\quad + \frac{1}{6} t_3 (1 + x_3 P_{12}^\sigma) \rho^\alpha \left( \frac{r_1 + r_2}{2} \right) \delta(r_1 - r_2) \\
\quad + i W_0 \overrightarrow{k}_{12} \delta(r_1 - r_2) (\overrightarrow{\sigma}_1 + \overrightarrow{\sigma}_2) \times \overrightarrow{k}_{12} 
\]

where, \( P_{12}^\sigma \) is the spin exchange operator, \( \overrightarrow{\sigma}_i \) is the Pauli spin operator, \( \overrightarrow{k}_{12} = -i(\overrightarrow{\nabla}_1 - \overrightarrow{\nabla}_2)/2 \) and \( \overrightarrow{k}_{12} = -i(\overrightarrow{\nabla}_1 - \overrightarrow{\nabla}_2)/2 \). Here, the right and left arrows indicate that the momentum operators act on the right and on the left, respectively. The Skyrme parameters \( t_i \), \( x_i \) and \( \alpha \) for a fixed value of \( W_0 \) can be expressed in terms of the quantities associated with the symmetric nuclear matter as follows\(^2,4,9\).

\[
t_0 = \frac{8}{\rho_{nm}} \left[ \left( -\frac{B}{A} + \frac{(2m/m^*) - 3}{10m} (h^2/10m) k_f^2 \right) \left( \frac{1}{27} K_{nm} - \frac{1}{10} (6m^*/5m) (h^2/9m^*) k_f^2 \right) \\
\quad - \frac{B}{A} + \frac{1}{9} K_{nm} - (4m/3m^* - 1) (h^2/10m) k_f^2 \\
\quad + \left( 1 - \frac{5m}{3m^*} \right) \frac{h^2}{10m} k_f^2 \right],
\]

(2)
\[ t_1 = \frac{2}{3} [T_0 + T_s], \]  

\[ t_2 = t_1 + \frac{8}{3} \left[ \left( \frac{1}{4} t_0 + \frac{1}{24} t_3 \rho_{nm}^{\alpha+1} \right) \frac{2 m^* k_f}{\hbar^2 \pi^2} + G'_0 \right] \frac{\hbar^2}{m^* \rho_{nm}}, \]  

\[ t_3 = \frac{16}{\rho_{nm}^{\alpha+1} - B/A + \frac{1}{5} K_{nm} - (4m/3m^* - 1)(\hbar^2/10m) k_f^2}, \]  

\[ x_0 = \frac{4}{t_0 \rho_{nm}} \left[ \frac{\hbar^2}{6m} k_f^2 - \frac{1}{24} t_3 (x_3 + \frac{1}{2} \rho_{nm}^{\alpha+1} + \frac{1}{24} (t_2 (4 + 5 x_2) - 3t_1 x_1) \rho_{nm} k_f^2 - J) \right] - \frac{1}{2}, \]  

\[ x_1 = \frac{1}{t_1} \left[ 4 \frac{\hbar^2 \kappa}{m \rho_{nm}} - t_2 (2 + x_2) \right] - 2, \]  

\[ x_2 = \frac{1}{4t_2} [8T_0 - 3t_1 - 5t_2], \]  

\[ x_3 = -\frac{8}{\alpha t_3 \rho_{nm}^{\alpha+1}} \left[ \frac{\hbar^2}{6m} k_f^2 - \frac{1}{12} ((4 + 5 x_2) t_2 - 3t_1 x_1) \rho_{nm} k_f^2 - 3J + L \right] - \frac{1}{2}. \]  

\[ \alpha = \frac{B/A - \frac{1}{5} K_{nm} + (4m/3m^* - 1)(\hbar^2/10m) k_f^2}{-B/A + (2m/m^* - 3)(\hbar^2/10m) k_f^2}, \]  

where,

\[ T_0 = \frac{1}{8} (3t_1 + (5 + 4x_2)t_2) = \frac{\hbar^2}{m \rho_{nm}} \left( \frac{m}{m^*} - 1 \right), \]  

\[ T_s = \frac{1}{8} [9t_1 - (5 + 4x_2)t_2], \]  

and

\[ k_f = \left( \frac{3\pi^2 \rho_{nm}}{2} \right)^{1/3}. \]  

In Eqs. (2)-(10), the various quantities characterizing the nuclear matter are the binding energy per nucleon \( B/A \), isoscalar effective mass \( m^*/m \), nuclear matter incompressibility coefficient \( K_{nm} \), symmetry energy coefficient \( J \), the coefficient \( L \) which is directly related to the slope of the symmetry energy coefficient \( (L = 3\rho dJ/d\rho) \), enhancement factor \( \kappa \) and Landau parameter \( G'_0 \). All these quantities are taken at the saturation density \( \rho_{nm} \). It must
be pointed out that we include consistently all terms in the energy density functional. In particular, the expression for the parameter $G'_0$ used in the Eq. (11) is consistent with the energy density functional obtained using Eq. (1). For a more generalized Skyrme energy density functional, the expression for $G'_0$ should be appropriately modified following Ref. [7]. Once, $T_0$ is known, $T_s$ can be calculated for a given value of the surface energy $E_s$ as

$$E_s = 8\pi r_0^2 \int_0^{\rho_{nm}} d\rho \left[ \frac{\hbar^2}{36m} - \frac{5}{36} T_0 \rho + \frac{1}{8} T_s \rho - \frac{m^*}{\hbar^2 V_{so}} \rho^2 \right]^{1/2} \frac{[B(\rho_{nm})/A - B(\rho)/A]^{1/2}}{\left[ B(\rho_{nm})/A - B(\rho)/A \right]^{1/2}}$$

where, $B(\rho)/A$ is the binding energy per nucleon given by,

$$\frac{B(\rho)}{A} = -\left[ \frac{3\hbar^2}{10m^*} k_f^2 + \frac{3}{8} T_0 \rho + \frac{1}{16} t_3 \rho^{\alpha+1} \right]$$

and,

$$r_0 = \left[ \frac{3}{4\pi \rho_{nm}} \right]^{1/3}, \quad V_{so} = \frac{9}{16} W_0^2.$$ 

The manner in which Eqs. (2) - (10) can be used to evaluate the Skyrme parameters $t_i$, $x_i$ and $\alpha$ is as follows. First, the parameters $t_0$ and $\alpha$ can be obtained from Eqs. (2) and (10), respectively. Then, the parameter $t_3$ can be calculated using Eq. (5). Next, $T_0$ and $T_s$ can be calculated using Eqs. (11) and (14), respectively. Once, the combinations $T_0$ and $T_s$ of the Skyrme parameters are known, one can calculate the remaining parameters in the following sequence, $t_1$, $t_2$, $x_2$, $x_1$, $x_3$ and $x_0$.

The stability criteria requires that

$$X_l > -(2l + 1),$$

where, $X_l$ stands for the Landau parameters $F_l$, $F'_l$, $G_l$ and $G'_l$ for a given multipolarity $l$. The Skyrme interaction only contains monopolar and dipolar contributions to the particle-hole interaction so that all Landau parameters are zero for $l > 1$. Thus, there are 12 different Landau parameters, i.e., $F_l$, $F'_l$, $G_l$ and $G'_l$ ($l = 0, 1$) for the symmetric nuclear matter and $F_l^{(n)}$, $G_l^{(n)}$ ($l = 0, 1$) for the pure neutron matter. Each of these Landau parameters must satisfy the inequality condition given by Eq. (17). Using the expressions for the Landau parameters in terms of the Skyrme parameters, given in Refs. [4], one can obtain the values of the Landau parameters at any density for a given set of the Skyrme parameters. Thus,
the critical density which is nothing but the maximum density up to which all the inequality conditions are met can be easily determined.

We have compiled the values of $\kappa$, $L$ and $G'_0$ for several parameterization of the Skyrme interaction presented in Refs. [2,3,11-16]. We find that the values of $\kappa$, $L$ and $G'_0$ vary over a wide ranges $0 - 2$, $40 - 160$ MeV and $-0.15 - 1.0$, respectively. This is due to the fact that the experimental data used in the least-square procedure to fit the values of the Skyrme parameters can not constrain well the values of these quantities. These quantities can be constrained by requiring a reasonable value for the critical density. In what follows, we shall refer to the set of standard values for six quantities $\rho_{nm} = 0.16\text{fm}^{-3}$, $B/A = 16$ MeV, $K_{nm} = 230$ MeV, $m^*/m = 0.7$, $E_s = 18$ MeV and $J = 32\text{MeV}$ in short as the STD values for the nuclear matter input as used in Ref. [4].

We now study the dependence of $\rho_{cr}$ on the $\rho_{nm}$, $B/A$, $m^*/m$, $K_{nm}$, $E_s$ and $J$. For a given set of values for these quantities, we calculate the maximum value of $\rho_{cr}$ by varying $\kappa$, $L$ and $G'_0$ at the $\rho_{nm}$ within acceptable limits. We denote the maximum value of the critical density by $\tilde{\rho}_{cr}$. It must be emphasized here that the present work differs from the one performed in Ref. [4] by the fact that we constrain the values of $\kappa$, $L$ and $G'_0$, whereas, in Ref. [4], the value of $\tilde{\rho}_{cr}$ was calculated by varying the combinations $t_i x_i$ ($i = 1, 2, 3$) of Skyrme parameters with no restrictions. We find that if the space of the parameters $t_i x_i$ is not restricted, it may lead to an unreasonable values of $\kappa$ and $L$. As an example, for the STD values of nuclear matter input, $\tilde{\rho}_{cr}$ becomes $3.5 \rho_0$ for $\kappa = 1.0$, $L = 36$ MeV and $G'_0 = 0.20$ (at $\rho_0$). The value of $G'_0$ seems reasonable, but the value of $\kappa = 1.0$ is a little too large [2, 6]. Further, we find that for $\rho > \rho_0$ the value of $L$ decreases with increasing $\rho$ and it becomes negative for $\rho > 1.6 \rho_0$, which makes the interaction not favorable for the neutron star model.

In Fig. [14] we have displayed the results for $\tilde{\rho}_{cr}$ obtained by varying the various quantities associated with the nuclear matter around their standard values. To calculate $\tilde{\rho}_{cr}$ we allow for $0.25 \leq \kappa \leq 0.5$, $0 \leq L \leq 100$ MeV and $0 \leq G'_0 \leq 0.5$ at the $\rho_{nm}$. We further demand that $L > 0$ at $3\rho_0$. Fig. [14] shows that $\tilde{\rho}_{cr}$ depends strongly on $m^*/m$ and $E_s$. Whereas, $\tilde{\rho}_{cr}$ depends weakly on $\rho_{nm}$, $B/A$ and $K_{nm}$ and it is almost independent of $J$. These features for $\tilde{\rho}_{cr}$ are qualitatively similar to the ones presented in Ref. [4]. However, due to the restrictions imposed on the values of $\kappa$, $L$ and $G'_0$, the values of $\tilde{\rho}_{cr}$ becomes smaller than that obtained in Ref. [4] by up to 25%. For $m^*/m = 0.6$ (0.7) and keeping all the other nuclear matter
quantities equal to their standard values, we get \( \tilde{\rho}_{cr} = 4.5\rho_0 \) (2.8\( \rho_0 \)) compared to \( 6\rho_0 \) (3.5\( \rho_0 \)) obtained in Ref. [4].

It may be instructive to present the values of \( \kappa, L \) and \( G'_0 \) required to obtained \( \tilde{\rho}_{cr} \) for a given set of values for the nuclear matter input. We find that \( \kappa \) lies in the range of 0.45 – 0.5 for variations in the nuclear matter input by up to \( \pm 15\% \) relative to their standard values. These values of \( \kappa \) clearly reflects the fact that restricting \( \kappa \) to take values in the range of 0.25 – 0.5 delimits the \( \tilde{\rho}_{cr} \) to a lower value. In Figs. 2a and 2b we have plotted the values of \( L \) and \( G'_0 \) (at \( \rho_{nm} \)), respectively, which are needed to yield the \( \tilde{\rho}_{cr} \). We see that \( L \) varies from 20 to 60 MeV for different values of the nuclear matter input. For the STD values of nuclear matter input we find that \( L = 47 \) MeV at \( \rho = \rho_0 \). This value is quite large compared to the values of \( L = 35, 27 \) and 16 MeV associated with the the Skz0, Skz1 and Skz2 interactions [4], respectively, which were obtained for the same standard values of the nuclear matter input, but by varying the combinations \( t_1x_1 \) and \( t_2x_2 \) with no restrictions and keeping \( t_3x_3 \) fixed to some arbitrary values. We see from Fig. 2b that, except for \( J \), the value of \( G'_0 \) (at \( \rho_{nm} \)) depends strongly on the values of the various quantities associated with nuclear matter. The dependence of \( G'_0 \) on the surface energy coefficient \( E_s \) is the most pronounced one. We note that \( E_s \) is mainly determined by the ground state properties of light nuclei. Thus, the center of mass correction to the binding energy and charge radii must be appropriately taken into account as they are very important for light nuclei and may affect the values obtained for \( E_s \). We see from Fig. 2b that \( G'_0 \) tends to vanish rapidly with increasing \( E_s \).

As pointed out earlier (see from Fig. 1), the dependence of \( \tilde{\rho}_{cr} \) on \( \rho_{nm}, J, \) and \( B/A \) is quite weak. Thus, it may be sufficient to calculate \( \tilde{\rho}_{cr} \) as a function of \( m^*/m, E_s \) and \( K_{nm} \) only. In Fig. 3 we display our results for the variation of \( E_s \) versus \( m^*/m \), obtained for fixed values of \( \tilde{\rho}_{cr} \) with the remaining nuclear matter quantities kept equal to their standard values. It can be seen from Fig. 3 that for a fixed value of \( \tilde{\rho}_{cr}, E_s \) decreases with the increase in \( m^*/m \). It is quite interesting to note that for \( E_s = 18 \pm 1 \) MeV (as most of the Skyrme interactions yield), \( \tilde{\rho}_{cr} = 2\rho_0 \) and \( 3\rho_0 \) for \( m^*/m = 0.72 – 0.85 \) and \( 0.63 – 0.73 \), respectively. For \( \tilde{\rho}_{cr} = 4\rho_0 \) one must have \( m^*/m \sim 0.65 \) for not too low value of \( E_s \). The value of \( m^*/m \) is also constrained by the centroid energy of the isoscalar giant quadrupole resonance which favors \( m^*/m \geq 0.7 \). Thus, for reasonable values of \( E_s \) and \( m^*/m \), one may obtain a Skyrme interaction with \( \tilde{\rho}_{cr} = 2\rho_0 \) to 3\( \rho_0 \).
In summary, we have used the stability conditions of the Landau parameters for the symmetric nuclear matter and pure neutron matter to calculate the critical densities for the Skyrme type effective nucleon-nucleon interactions. We find that the critical density can be maximized by appropriately adjusting the values of the enhancement factor $\kappa$, coefficient $L$ and the Landau parameter $G_0'$ as these quantities are not well determined by the Skyrme parameters, conventionally obtained by fitting the experimental data for the ground state properties of finite nuclei. We exploit the fact that i) The value of $\kappa$ should be in the range of $0.25 - 0.5$, needed to describe the TRK sum rule for the isovector giant dipole resonance [2, 6], ii) $L > 0$ for $0 \leq \rho \leq 3\rho_0$; a condition necessary for a Skyrme interaction to be suitable for studying the properties of neutron star [5], and iii) $G_0' > 0$ in order to reproduce the energies of the isovector $M1$ and Gamow-Teller states [6]. The maximum value of the critical density so obtained is lower by up to 25% compared to the ones obtained without any such restrictions [4]. We show that the critical density obtained for realistic values of the surface energy coefficient ($E_s = 18 \pm 1$ MeV) and isoscalar effective mass ($m^*/m = 0.7 \pm 0.1$) lie in the range of $2\rho_0$ to $3\rho_0$. Finally, we would like to remark that the pairing correlations were not included in the present work. It may be worthwhile to investigate the influence of the pairing correlations on the various quantities associated with the nuclear matter which may alter the value of the critical density.
