Abstract

The requirement of Hermiticity of a Quantum Mechanical Hamiltonian, for the description of physical processes with real eigenvalues which has been challenged notably by Carl Bender, is examined for the case of a Fock space Hamiltonian which is bilinear in two creation and destruction operators. An interpretation of this model as a Schrödinger operator leads to an identification of the Hermitian form of the Hamiltonian as the Landau model of a charged particle in a plane, interacting with a constant magnetic field at right angles to the plane. When the parameters of the Hamiltonian are suitably adjusted to make it non-Hermitian, the model represents two harmonic oscillators at right angles interacting with a constant magnetic field in the third direction, but with a pure imaginary coupling, and real energy eigenvalues. It is now \(\mathcal{P}\mathcal{T}\) symmetric. Multiparticle states are investigated.
1 Introduction

The familiar Hamiltonians of Quantum Mechanics may be analysed for symmetries either in terms of pure matrix algebra, or else in terms of a Fock space representation, which generally leads to a more physical interpretation of the mathematical manipulations. In particular, any Hamiltonian constructed from a Fock space of \( n \) fermionic creation and annihilation operators may be transcribed in terms of a finite dimensional matrix of dimension \( 2^n \times 2^n \) on account of the fact that such operators can always be constructed from gamma matrices, which admit a well known matrix representation. The inverse of this construction, to obtain a Fock space representation of any finite dimensional Hermitian matrix can be done by embedding the matrix in a larger one of suitable dimension to admit representations of the canonical anti-commutation relations. In fact, in view of the existence of a matrix representation for Hamiltonians the transcription is merely an exercise in matrix algebra for undergraduates. However, the situation is more complicated when the Hamiltonian is no longer Hermitian. It is a central tenet of Quantum Theory and Quantum Field Theory that the Hamiltonian should be Hermitian, but this is not in fact necessary to maintain real eigenvalues, as has been demonstrated in recent years, notably by Bender and Boettcher [2]. However, if the eigenvalues are all discrete and real and their eigenvectors span the full space, there will exist, in general, an infinity of Hermitian Hamiltonians (possibly infinite dimensional) which are unitarily equivalent to the diagonal (real) form. They are equivalent up to a more general (not necessarily unitary) transformation to the initial Hamiltonian.

If all the eigenvalues are real and their eigenvectors span a subspace \( S \) of the initial space (say finite dimensional to make things simpler) there exists, in general, an infinity of Hamiltonians unitarily equivalent to a Jordan form (or a generalised Jordan form in the infinite dimensional case) and equivalent up to a more general (non necessary unitary) to the initial Hamiltonian. These Hamiltonians projected to the subspace \( S \) are Hermitian.

If some of the eigenvalues are discrete and real, this same statement will obviously apply in the subspace of the corresponding eigenvectors. We shall study a simple example which illustrates this in a physical context, that of the Landau problem of a particle in two dimensions moving under the influence of a constant magnetic field in the third direction [5] [6], and show that this model exhibits the features which have been found for \( \mathcal{PT} \) symmetric non-Hermitian systems. In particular, while the usual model is Hermitian, with
a real magnetic coupling, a deformation of the parameters in this model leads under certain systems to a non-Hermitian system with real eigenvalues and an imaginary coupling. In this respect it recalls to mind the work of Hollowood [3], who showed that affine Toda field theory with pure imaginary coupling possesses real energy levels. This system represents an anisotropic oscillator in interaction with a constant magnetic field. Some discussion is given of the case of transition between the Hermitian and non-Hermitian case, where two of the eigenvalues coincide, and the associated matrix cannot be fully diagonalised, but can be reduced by similarity transformations only to Jordan Normal form.

2 Two-dimensional Case

Take a $2 \times 2$ matrix

$$M = \begin{bmatrix} s_1 & s_3 \\ s_4 & s_2 \end{bmatrix}. \quad (1)$$

Then any finite dimensional matrix eigenvalue problem can always be transformed to an infinite dimensional Quantum Mechanical eigenvalue problem by the introduction of Fock space creation and annihilation operators $a_i^\dagger, a_j$, so that matrix $M_{ij}$ turns into the Hamiltonian $\sum_{i,j} a_i^\dagger M_{ij} a_j$. This gives in this case the Hamiltonian

$$H = s_1 a_1^\dagger a_1 + s_2 a_2^\dagger a_2 + s_3 a_1^\dagger a_2 + s_4 a_2^\dagger a_1, \quad (2)$$

where the coefficients $s_i, \; i = 1 \ldots 4$ are complex constants and $a_i^\dagger, a_i$ are two creation and annihilation operators satisfying the usual canonical commutation relations, with only the following non-zero commutators,

$$a_i a_j^\dagger - a_j^\dagger a_i = \delta_{ij}. \quad (3)$$

The vacuum state $|0\rangle$ is defined as usual as the normalized state which is annihilated by the $a$’s

$$a_i \mid 0 \rangle = 0 \quad (4)$$

where $0$ is the zero norm state in the Hilbert space.
3 Diagonalisation

Define
\[ \Delta = \sqrt{(s_1 - s_2)^2 + 4s_3s_4}; \quad \lambda_{\pm} = \frac{1}{2}(s_2 - s_1) \pm \frac{1}{2}\Delta, \]
and construct the linear combinations
\[ \alpha_1^+ = n_1 \left( \frac{s_3}{\lambda_+} a_1^+ + a_2^+ \right) \]
\[ \alpha_2^+ = n_2 \left( \frac{s_3}{\lambda_-} a_1^+ + a_2^+ \right) \]
\[ \alpha_1 = \frac{1}{n_1} \left( \frac{s_4}{\Delta} a_1 + \frac{\lambda_+}{\Delta} a_2 \right) \]
\[ \alpha_2 = \frac{1}{n_2} \left( \frac{-s_4}{\Delta} a_1 + \frac{-\lambda_-}{\Delta} a_2 \right). \]

In this construction, \( \alpha_j^+ \) denotes a creation operator, which should not be thought of as the Hermitian conjugate of \( \alpha_j \) which is also a destruction operator, since there is no Hermitian Hamiltonian \( (\alpha_j^\dagger \neq \alpha_j^-) \). However the properties
\[ <0 | \alpha_i \alpha_j^+ | 0> = \delta_{ij} \]
hold. Indeed the \( \alpha_j \)'s and \( \alpha_j^+ \)'s satisfy exactly the same commutation relations as do the \( a \)'s, as a consequence of the fact that the matrix \( [1] \) can be diagonalised by a similarity transform.

This implies that observables in the theory can be calculated, as \( n \) particle states will have the form
\[ | r, n-r > = \frac{1}{\sqrt{r!(n-r)!}} (\alpha_1^+)^r (\alpha_2^+)^{n-r} | 0 >. \]

These states are orthogonal to the following adjoint states
\[ | adj[r, n-r] > = \frac{1}{\sqrt{r!(n-r)!}} (\alpha_1^\dagger)^r (\alpha_2^\dagger)^{n-r} | 0 > \]
in the sense that
\[ < adj[p', q'] | p, q > = \delta_{p'p} \delta_{q'q}. \]
The limitation of the use of non-Hermitian Hamiltonians is that the notion of conjugation and reality of eigenvalues is specific to the Hamiltonian used and is not universal as is the case with Hermitian conjugation, as Bender et al have remarked \[1\]. Hermiticity also guarantees reality of eigenvalues, independently of details of the Hamiltonian. This universality is a consequence of the fact that the inverse of a unitary matrix, which diagonalises a Hermitian matrix, is its own Hermitian conjugate, i.e. since \(U^\dagger = U^{-1}\) for a unitary matrix \(U\) the columns of \(U^\dagger\) are orthogonal to the rows of \(U\), the operation of Hermitian conjugation works independently of the Hermitian matrix to be diagonalised. In the case of a 2 \(\times\) 2 matrix \(H\) we have

\[
H = s_1 a_1^\dagger a_1 + s_2 a_2^\dagger a_2 + s_3 a_1^\dagger a_2 + s_4 a_2^\dagger a_1 \\
= \frac{1}{2} (s_1 + s_2 + \Delta) a_1^\dagger a_1 + \frac{1}{2} (s_1 + s_2 - \Delta) a_2^\dagger a_2.
\]

(14)

This construction shows that the \(n\) particle states have energies of the form

\[
E_{n,m} = \frac{n}{2} (s_1 + s_2) + \frac{m}{2} \Delta,
\]

(15)

where \(m\) runs from \(-n\) to \(n\) in steps of 2. There are several interesting features of this result. The eigenvalues will be real and distinct provided \(s_1 + s_2\) is real and \((s_1 - s_2)^2 + 4s_3 s_4\) is positive, thus even when the Hamiltonian is non-Hermitian, the eigenvalues may be real. When this latter factor is zero, then the eigenvalues are degenerate. Then, either the Hamiltonian is proportional to the unit matrix \((s_1 = s_2, s_3 = s_4 = 0)\) or, if at least one off-diagonal element is non zero, there is one eigenvector only and the Hamiltonian can be brought to the normal form \((s_1' = s_2', s_3' = 0, s_4' = 1)\). These cases are briefly discussed later. For non-Hermitian Hamiltonians, Bender et al \[1\] have analysed the existence of a Parity operator \(P\) and a Conjugation matrix \(P^T\). These crucial issues will be taken up and generalised after we demonstrate a simple application to a physical example of the 2 \(\times\) 2 situation detailed above.

4 Schrödinger interpretation

The above problem is equivalent up to a constant energy shift to solving a Schrödinger equation for a particular Quantum Mechanical problem; set
\( a_i = p_i + iq_i \) etc; then the problem is equivalent to

\[
H = -s_1 \left( \frac{\partial^2}{\partial x^2} - x^2 \right) - s_2 \left( \frac{\partial^2}{\partial y^2} - y^2 \right) \\
- (s_3 + s_4) \left( \frac{\partial^2}{\partial x \partial y} - xy \right) + (s_3 - s_4) \left( x \frac{\partial}{\partial y} - y \frac{\partial}{\partial x} \right) \quad (16)
\]

up to a \( c \)-number addition. If \( s_3 = -s_4 \), then this is the Landau problem of a particle in a plane coupled to a magnetic field in the perpendicular direction, through its angular momentum with possibly an additional linear central force. To see this consider a constant magnetic field with potential \( \vec{A} = \frac{B}{2} (x) \) in the Hamiltonian

\[
H = \frac{1}{2m} (\vec{p} + \frac{e}{c} \vec{A})^2 \\
= \frac{1}{2m} \left( p_x^2 + p_y^2 + \left( \frac{eB}{2c} \right)^2 (x^2 + y^2) + \frac{eB}{c} (p_y x - p_x y) \right) \quad (17)
\]

and make the identifications; \( s_1 = s_2 = 1/(2m) \), and \( s_3 = -s_4 \) is pure imaginary. This Hamiltonian is Hermitian with real eigenvalues. However, the choice of \( s_3 = -s_4 \) and real, eliminates the \( xy \) cross terms and also gives real eigenvalues, provided that the factor \((s_1 - s_2)^2 - 4s_4^2\) is positive which necessarily entails that \( s_1 \neq s_2 \). In this case the Hamiltonian is non-Hermitian and it represents a constant magnetic field coupled to an anisotropic oscillator with pure imaginary coupling. In all the examples Bender et al [2][3] have constructed with non-Hermitian Hamiltonians and real eigenvalues the Hamiltonian is \( \mathcal{P}\mathcal{T} \) symmetric. Dorey, Dunning and Tateo [7] have recently given a proof that the spectra of a number of \( \mathcal{P}\mathcal{T} \) invariant Hamiltonians are entirely real. However, on its own \( \mathcal{P}\mathcal{T} \) invariance only implies real or complex conjugate pairs of eigenvalues. This is the situation under consideration here as \( \mathcal{P}\mathcal{T} \) invariance means invariance under \((x, y) \rightarrow (-x, -y)\) and \( i \rightarrow -i \). At the same time \( \vec{p} \) does not change. The Hamiltonian will then be \( \mathcal{P}\mathcal{T} \) symmetric since \( B \rightarrow B \), but the eigenvalues may be complex conjugate if the positivity condition is violated.

## 5 Real Eigenvalue conditions

As is well known, the eigenvalues of a Hermitian matrix are always real. In general the condition for the reality of eigenvalues depends on more specific
details of the matrix. However in the case of an \( n \times n \) matrix \( H \) necessary conditions for the existence of real eigenvalues are given by

\[
\text{Trace}(H^r) = \text{real}; \quad r = 1, 2, \ldots, n .
\] (18)

This result follows simply from the observations that the characteristic polynomial of \( H \), being an invariant under similarity transformations, has coefficients expressible in terms of the traces of powers of \( H \) and that if all the eigenvalues are real, \( H^\dagger \) must have the same eigenvalues as \( H \). A further necessary and sufficient condition for an arbitrary \( 2 \times 2 \) matrix to possess real eigenvalues is given by the requirement that

\[
2\text{Trace}H^2 - (\text{Trace}H)^2 \geq 0 .
\]

This expression is just a translation into invariant form of the condition of section (2). Unfortunately, an invariant criterion even in the 3 dimensional case is rather complicated. When the traces are real and \( \Delta = 0 \), the two dimensional matrix \( H \) may be expressed as

\[
H = \frac{1}{2}(s_1 + s_2)\mathbb{I} + A
\] (19)

where \( A \) is null or the zero matrix; i.e Trace\( A = \text{Trace}A^2 = 0 \) or \( A = 0 \). In the former case the matrix is equivalent by a change of basis to a Jordan Normal Form

\[
H = \begin{bmatrix}
a & 1 \\
0 & a
\end{bmatrix} .
\] (20)

6 “Conjugation” and “Parity”. Finite Dimensional Case

In this section, we extend the notions of “conjugation”, and/or of “parity” introduced in [2] to arbitrary finite dimensional matrices representing the Hamiltonian with real eigenvalues. In certain cases the arguments can be extended immediately to infinite dimensional spaces (see Section (8) for an example). It is also not difficult to extend them to the case where some of the eigenvalues are equal or are complex or when the starting matrix \( M_d \) below has parts in a Jordan form.

We first recall a few well-known facts. Let \( M_d \) be a real diagonal matrix in \( p \) dimensions with, for later simplicity, all elements different

\[
(M_d)_{ij} = \mu_j \delta_{ij} , \quad \mu_j = \mu_j^* , \quad \mu_i \neq \mu_j \quad \text{when} \ i \neq j ,
\] (21)
and let $N$ be an arbitrary invertible $p \times p$ complex matrix. Let the scalar product of the column eigenvectors $\psi$ and $\phi$ be defined by the obvious

$$<\psi | \phi> = \psi^\dagger \phi \quad (22)$$

where $A^\dagger = (A^*)^p$ is the Hermitian conjugate matrix.

For any matrix $M$ which has the eigenvalues $\mu_i$ there exists a matrix $N$ such that

$$M = N M_d N^{-1} \iff M_d = N^{-1} M N \quad (23)$$

The $p$ vectors $\phi_i, i=1,\ldots,p$, with components

$$(\phi_i)_j = \delta_{ij} \quad (24)$$

are obviously eigenvectors of $M_d$ with eigenvalues $\mu_i$. They are orthonormal for the scalar product

$$<\phi_j | \phi_k> = \delta_{jk} \quad (25)$$

The vectors $\psi_i = N \phi_i$ are obviously eigenvectors of the general $M$ with the same eigenvalue.

We now present a few results providing, in the rather general case (21), the general solution to the question of existence and construction of a suitable scalar product $<\phi | \psi>_G$, of a “parity” operator $P$ and of a “conjugation” operator $C$.

1. The vectors $\psi_i$ are orthonormal for the Hermitian scalar product (26) defined by

$$<\psi | \phi>_G = \psi^\dagger G \phi \quad \text{with} \quad G = (N^{-1})^\dagger N^{-1} \quad (26)$$

Indeed

$$\delta_{jk} = <\phi_j | \phi_k> = <N^{-1} \psi_j | N^{-1} \psi_k> = \psi_j^\dagger (N^{-1})^\dagger N^{-1} \psi_k = \psi_j^\dagger G \psi_k = <\psi_j | \psi_k>_G \quad (27)$$

Because of the form of $G$ (26) all the requirements of the scalar product are met. Note however that if $N$ is unitary, then $G$ is the identity.
matrix; otherwise, it depends upon the structure of $N$. This means that while Hermitian conjugation can be defined universally for Hermitian Hamiltonians. In the non-Hermitian case, it is a more specific matrix. Two matrices $M$ lead to the same metric $G$ if the $N$ which defines the first one is equal to the $N$ which defines the second multiplied by an arbitrary unitary matrix.

2. We denote complex by $T$ the symbolic operator which performs the $c$-number conjugation, $T$

$$TA = A^*T. \tag{28}$$

There exist always a matrix $P$ (generically called “parity” as Bender suggested) which has the following property

$$(PT)M = M(PT) \quad PM^* = MP. \tag{29}$$

Take any invertible matrix $K$ which commutes with $M_d$,

$$KM_d = M_dK. \tag{30}$$

In particular any diagonal matrix will do if the eigenvalues since are all different. If some eigenvalues are equal, $K$ may belong to the stability group of $M_d$. Then

$$P = NK(N^*)^{-1}. \tag{31}$$

Indeed

$$PM^* = MP \quad P \left( N M_d N^{-1} \right)^* = N M_d N^{-1}P \quad \text{by (23)} \quad PN^* M_d (N^{-1})^* = N M_d N^{-1}P \quad \text{by (21)} \quad \left( N^{-1} P N^* \right) M_d = M_d \left( N^{-1} P N^* \right). \tag{32}$$

Using (31) and (32), the statement is proved.

3. The matrix $C$ (conjugation) is defined as having the following property

$$CM = MC \quad C^2 = 1. \tag{33}$$
The general solution for $C$ is

$$C = NK_sN^{-1}$$ (34)

where $K_s$ is such it commutes with $M_d$ and $K_s^2 = \mathbb{1}$. In the generic case, $K_s$ is a diagonal matrix with elements $\pm$ only. Up to a trivial overall sign, there are $2^{p-1}$ independent $C$’s. Indeed the first equation of (29) gives

$$CM = MC$$

$$CNM_dN^{-1} = N M_dN^{-1}C$$ by (23)

$$(N^{-1}CN)M_d = M_d(N^{-1}CN)$$ (35)

which implies that $N^{-1}CN = K$ commutes with $M_d$. The second equation implies moreover that

$$K^2 = \mathbb{1}.$$ (36)

In the two dimensional example of section (2), $C$ is either the identity matrix or the matrix

$$C = \frac{1}{\Delta} \begin{bmatrix} s_1 - s_2 & 2s_3 \\ 2s_4 & s_2 - s_1 \end{bmatrix}$$ (37)

up to sign.

7 More Bosonic Creation Operators

In this section, we elaborate on two or more particle states obtained for the simplest Hamiltonian (2). We will treat in great detail the two and four particles states.

7.1 Two Particle States

Let us first elaborate on the two particle states constructed from the operators of section (2). Suppose that we were to start with the products $b_i^\dagger$, $i = 1, 2, 3$ of two creation operators

$$b_1^\dagger = (a_1^\dagger)^2$$
$$b_2^\dagger = a_1^\dagger a_2^\dagger$$
$$b_3^\dagger = (a_2^\dagger)^2$$ (38)
which construct the three two-particle states $b_i^\dagger \ket{0}$, $i = 1, 2, 3$ when applied to the vacuum of the $a_i$ operators. The corresponding three-dimensional matrix $M$ is

$$M^{[2]} = \begin{pmatrix} 2s_1 & s_3 & 0 \\ 2s_4 & s_1 + s_2 & 2s_3 \\ 0 & s_4 & 2s_2 \end{pmatrix}.$$  \hspace{1cm} (39)

It satisfies (with $H$ from (2))

$$[H, b_i^\dagger] = M^{[2]}_{ji} b_j^\dagger$$  \hspace{1cm} (40)

and hence

$$H b_i^\dagger \ket{0} = M^{[2]}_{ji} b_j^\dagger \ket{0}.$$  \hspace{1cm} (41)

The diagonalisation of $M$ provides the two particle spectrum. Using $\Delta$ from (4), we find, as expected, three eigenstates $\beta_i^+$ which fulfill the eigenvalue equation (with $H$ from (2))

$$H \beta_i^+ \ket{0} = \mu_i \beta_i^+ \ket{0}.$$  \hspace{1cm} (42)

They are up to a factor, obviously from (2)

$$\beta_1^+ = -2s_3^2 b_1^\dagger + 2s_3(-\Delta + s_1 - s_2)b_2^\dagger + (\Delta(s_1 - s_2) - (s_1 - s_2)^2 - 2s_3s_4)b_3^\dagger \propto (\alpha_1^+)^2$$

$$\beta_2^+ = -s_3b_1^\dagger + (s_1 + s_2)b_2^\dagger + s_4b_3^\dagger \propto \alpha_1^+ \alpha_2^+$$

$$\beta_3^+ = -2s_3^2 b_1^\dagger + 2s_3(\Delta + s_1 - s_2)b_2^\dagger + (-\Delta(s_1 - s_2) - (s_1 - s_2)^2 - 2s_3s_4)b_3^\dagger \propto (\alpha_2^+)^2$$  \hspace{1cm} (43)

with eigenvalues (see (15))

$$\mu_1 = s_1 + s_2 + \Delta = E_{2,1} = 2E_{1,1}$$

$$\mu_2 = s_1 + s_2 = E_{2,0} = E_{1,1} + E_{1,-1}$$

$$\mu_3 = s_1 + s_2 - \Delta = E_{2,-1} = 2E_{1,-1}.$$  \hspace{1cm} (44)

This discussion suggests the following question: how can this spectrum be obtained directly from the operators defining the two-particle space? We will first show that a naïve approach has strong shortcomings.
1. A first naïve answer is as follows. Introduce symbolically the new operators $\overline{b}_i$ which are supposed, with the $b_j^\dagger$, to satisfy the canonical commutation relations

$$[\overline{b}_i, b_j^\dagger] = \delta_{ij}$$  \hspace{1cm} (45)

and define a two particle Hamiltonian $H_{\text{naive}}^{[2]}$ as

$$H_{\text{naive}}^{[2]} = b_i^\dagger M_{ij}^{[2]} b_j .$$  \hspace{1cm} (46)

Then obviously but, we insist, symbolically we obtain

$$[H_{\text{naive}}^{[2]}, b_i^\dagger] = M_{ji}^{[2]} b_j^\dagger$$  \hspace{1cm} (47)

and on a vacuum $\mid 0^{[2]} >$ such that

$$\overline{b}_j \mid 0^{[2]} > = 0$$  \hspace{1cm} (48)

we obtain

$$H_{\text{naive}}^{[2]} b_i^\dagger \mid 0^{[2]} > = M_{ji}^{[2]} b_j^\dagger \mid 0^{[2]} > .$$  \hspace{1cm} (49)

It is not difficult to see that it is impossible to construct $\overline{b}_i$ satisfying (45) out of products of two $a_j$. However if the vacuum $\mid 0^{[2]} >$ is thought to be the $a$ vacuum $\mid 0 >$

$$\mid 0^{[2]} : = \mid 0 >$$  \hspace{1cm} (50)

and the weaker condition

$$[\overline{b}_i, b_j^\dagger] \mid 0 > = \overline{b}_i b_j^\dagger \mid 0 > = \delta_{ij} \mid 0 >$$  \hspace{1cm} (51)

is imposed, the $\overline{b}_i$ can be identified to be

$$\overline{b}_1 = \frac{1}{2} b_1, \overline{b}_2 = b_2, \overline{b}_3 = \frac{1}{2} b_3 \quad \text{in the weak sense}$$  \hspace{1cm} (52)

with, obviously, $b_1 = a_1^2$, $b_2 = a_1 a_2$, $b_3 = a_2^2$. The equation (49) then holds.

2. In a second approach, one tries to construct directly an $H_{\text{naive}}^{[2]}$ quadratic both in $a_i^\dagger$ and in $a_i$ and which satisfies the basis equation (47)

$$[H_{\text{naive}}^{[2]}, b_i^\dagger] \mid 0 > = M_{ji}^{[2]} b_j^\dagger \mid 0 >$$  \hspace{1cm} (53)
as a result of the basic $a_i$ canonical commutation relations (3).

Such a Hamiltonian does not exist in the strong sense (when the vacuum is removed in (53)). In the weak sense, it exists as

$$H^{[2]} = b_i^\dagger N_i^{[2]} b_j .$$

where the matrix $N^{[2]}$ is

$$N^{[2]} = \begin{pmatrix}
    s_1 & s_3 & 0 \\
    s_4 & s_1 + s_2 & s_3 \\
    0 & s_4 & s_2
\end{pmatrix} .$$

(55)

This result is obviously equivalent to the naïve approach once the $\tilde{b}_i$ are expressed in terms of the $b_i$ (52).

### 7.2 Four Particle States

Let us proceed in the same way for the four particle states which can be thought either directly as the four particle states in the original operators ($a_i^\dagger$, $i = 1, 2$) (3)

$$d_i^\dagger = (a_i^\dagger)^{5-i} (a_2^\dagger)^{i-1} , \quad i = 1, \ldots, 5$$

or as the compound states constructed out of two of the basic two particle states $b_i^\dagger$, $i = 1, 2, 3$ (38)

$$d_i^\dagger = (b_i^\dagger)^2 , \quad d_2^\dagger = b_1^\dagger b_2^\dagger , \quad d_3^\dagger = b_1^\dagger b_3^\dagger , \quad d_4^\dagger = (b_4^\dagger)^2 .$$

(57)

Let us note immediately that there are only five states built with the five $d_i^\dagger$ while there are six states built with the six $\tilde{d}_i^\dagger$. This is due to the obvious fact that

$$d_3^\dagger \equiv \tilde{d}_4^\dagger$$

(58)

when constructed from the $a_i$.

Let us treat in succession the $d_i^\dagger$ case and the $\tilde{d}_i^\dagger$ case.

- The $5 \times 5$ matrix $M_i^{[4]}$, analogous to (39) and defined by

$$[H, d_i^\dagger] = M_i^{[4]} d_j^\dagger ,$$

(59)

12
is

\[
M^{[4]} = \begin{pmatrix}
4s_1 & s_3 & 0 & 0 & 0 \\
4s_4 & 3s_1 + s_2 & 2s_3 & 0 & 0 \\
0 & 3s_4 & 2(s_1 + s_2) & 3s_3 & 0 \\
0 & 0 & 2s_4 & s_1 + 3s_2 & 4s_3 \\
0 & 0 & 0 & s_4 & 4s_2 \\
\end{pmatrix}.
\] (60)

From this expression, it is easy to generalize to the general form for states with \( n \) original particles. Its eigenvalues and eigenstates, analogous to (43), (44) can be read off explicitly in (11) and (15).

Note that, in the weak sense, there is a Hamiltonian \( H^{[4]} \) which may be written directly in terms of the \( d_j \) and \( d_j^\dagger \)

\[
[H^{[4]}, d_j^\dagger] | 0 > = M^{[4]}_{ji} d_j^\dagger | 0 > 
\] (61)

and is

\[
H^{[4]} = d_j^\dagger N^{[4]}_{ij} d_j
\] (62)

with

\[
N^{[4]} = \frac{1}{6} \begin{pmatrix}
s_1 & s_3 & 0 & 0 & 0 \\
s_4 & 3s_1 + s_2 & 3s_3 & 0 & 0 \\
0 & 3s_4 & 3(s_1 + s_2) & 3s_3 & 0 \\
0 & 0 & 3s_4 & s_1 + 3s_2 & s_3 \\
0 & 0 & 0 & s_4 & s_2 \\
\end{pmatrix}.
\] (63)

Let us now try to define the 6 \( \times \) 6 matrix \( \tilde{M}^{[4]} \) in the same way for the \( d_i^\dagger \)

\[
[H^{[2]}_{\text{naive}}, d_i^\dagger] = \tilde{M}^{[4]}_{ji} d_j.
\] (64)

again starting from the same canonical commutation relations for the \( b_i^\dagger \)'s and \( \tilde{b}_j \) (45). We find

\[
\tilde{M}^{[4]}_{ij} = \begin{pmatrix}
4s_1 & s_3 & 0 & 0 & 0 & 0 \\
4s_4 & 3s_1 + s_2 & 2s_3 & 2s_3 & 0 & 0 \\
0 & s_4 & 2(s_1 + s_2) & 0 & s_3 & 0 \\
0 & 2s_4 & 0 & 2(s_1 + s_2) & 2s_3 & 0 \\
0 & 0 & 2s_4 & 2s_4 & s_1 + 3s_2 & 4s_3 \\
0 & 0 & 0 & 0 & s_4 & 4s_2 \\
\end{pmatrix}.
\] (65)
Since the $d_i^\dagger$ are perfectly defined there is no ambiguity. However, coherence with (58) implies that an arbitrary combination of $d_3^\dagger - d_4^\dagger$ can be added to the right-hand side of (64) and $\tilde{M}_{ij}^{[4 \prime]}$ can be replaced by

$$\tilde{M}_{ij}^{[4 \prime]} = \tilde{M}_{ij}^{[4]} + r_j \delta_{i3} - r_j \delta_{i4} .$$

namely

$$\tilde{M}_{ij}^{[4 \prime]} =
\begin{bmatrix}
4 s_1 & s_3 & 0 & 0 & 0 & 0 \\
4 s_4 & 3 s_1 + s_2 & 2 s_3 & 2 s_3 & 0 & 0 \\
r_1 & s_4 + r_2 & 2 (s_1 + s_2) + r_3 & r_4 & s_3 + r_5 & r_6 \\
-r_1 & 2 s_4 - r_2 & -r_3 & 2 (s_1 + s_2) - r_4 & 2 s_3 - r_5 & -r_6 \\
0 & 0 & 2 s_4 & 2 s_4 & s_1 + 3 s_2 & 4 s_3 \\
0 & 0 & 0 & 0 & s_4 & 4 s_2
\end{bmatrix}$$

Making the same combination for the left-hand side, it can easily be checked that

$$[H_{\text{naive}}^{[2]}, d_3^\dagger - d_4^\dagger] = (2 s_1 + 2 s_2 + r_3 - r_4)(d_3^\dagger - d_4^\dagger)$$

(68)
i.e. a combination of $d_3^\dagger - d_4^\dagger$ only. This result is coherent when $d_3^\dagger - d_4^\dagger$ is put to zero.

The eigenvalues of the matrix $\tilde{M}_{ij}^{[4 \prime]}$ depend upon the values of the arbitrary parameters $r_i$ since the secular equation is

$$(\lambda - E_{4,4})(\lambda - E_{4,-4})(\lambda - E_{4,2})(\lambda - E_{4,-2})(\lambda - E_{4,0})(\lambda - E_{4,0} - r_3 + r_4)$$

(69)

When $r_4 \neq r_3$, the eigenvalues are all different and the matrix can be diagonalised. When $r_4 = r_3$, two eigenvalues become equal. Then there is always the eigenvector $(0, 0, 1, -1, 0, 0)^\dagger$. The condition for the existence of a second eigenvector is

$$r_6 s_4^2 + 2 r_5 s_1 s_4 - 2 r_5 s_2 s_4 + r_3 (s_1 - s_2)^2 - 2 r_3 s_3 s_4$$
$$- 2 r_2 s_1 s_3 + 2 r_2 s_2 s_3 + r_1 s_3^2 = 0$$

(70)
When this condition is satisfied, the matrix can be transformed to a fully diagonal form; otherwise it is reducible to a Jordan Normal form

\[
\begin{bmatrix}
E_{4,4} & 0 & 0 & 0 & 0 \\
0 & E_{4,2} & 0 & 0 & 0 \\
0 & 0 & E_{4,0} & 1 & 0 \\
0 & 0 & 0 & E_{4,0} & 0 \\
0 & 0 & 0 & 0 & E_{4,-2} \\
0 & 0 & 0 & 0 & 0 & E_{4,-4}
\end{bmatrix}.
\]  

(71)

8 Extension to a Fock space

We shall now promote the discussion to the case of a Fock-space Hamiltonian linear in the products of one creation and one annihilation operator \(a_i^\dagger a_j\) of bosons of two (or more) different species. The matrices \(N\) now become functions of the creation and annihilation operators \((a_j, a_j^\dagger)\) which satisfy the usual canonical commutation relations (see (3)).

In analogy with the 2-dimensional case (14) and with the discussion of the preceding section, the diagonal Hamiltonian is defined as

\[
H_d = \sum_j \mu_j a_j^\dagger a_j
\]  

and the related Hamiltonian \(H\) by

\[
H = N H_d N^{-1}
\]  

which should be linear in the products \(a_i^\dagger a_j\) since this is a free field theory. Suppose

\[
Na_i N^{-1} = \sum_j c_{ij} a_j \quad (\equiv \alpha_i)
\]

\[
Na_i^\dagger N^{-1} = \sum_j d_{ij} a_j^\dagger \quad (\equiv \alpha_i^\dagger)
\]  

(74)

Indeed, we then find

\[
H = \sum_j \mu_j \left( \sum_k d_{jk} a_k^\dagger \right) \left( \sum_m c_{jm} d_m \right)
\]

15
\[ \sum_k \sum_m \left( \sum_j \mu_j d_{jk}^{[1]} c_{jm}^{[1]} \right) a_k^\dagger a_m. \quad (75) \]

If an interpretation in terms of creation and annihilation operators is to remain, the right hand sides of (74) should obey the same commutation relations \([8]\) as the \(a\)'s. This implies for the matrices \(c\) and \(d\) having respectively \(c_{ij}\) and \(d_{ij}\) as components the restrictions

\[ d_{ij}^{[1]} t^p = (c_{ij}^{[1]})^{-1}. \quad (76) \]

After some algebra, using (76) and defining

\[ d_{ij}^{[2]} = d_{ij}^{[1]} - \mathbb{1}, \quad (77) \]

one finds

\[ [a_i, N] = d_{ij}^{[2]} t^p N a_j \quad (78) \]
\[ [N, a_i^\dagger] = d_{ij}^{[2]} a_j^\dagger N. \quad (79) \]

Using a power expansion of \(N\) in terms of the \(a\)'s, it is easy to show that the quadratic part of \(N\) is

\[ Q = \sum_{ij} d_{ij}^{[2]} a_j^\dagger a_i, \quad (80) \]

and that the general \(N\) is constructed from \(Q\) as

\[ N =: \exp(Q) :, \quad (81) \]

where the symbol : : denotes the normal product (annihilation operators written at the right of creation operators). Indeed, we have

\[ [a_i, N] = \partial_{a_i^\dagger} : \exp(Q) : \]
\[ = : \exp(Q) : \left( \partial_{a_i^\dagger} Q \right) \]
\[ = N \left( \sum_j d_{ij}^{[2]} a_j \right) \quad \Leftrightarrow \quad \text{Eq. (78)} \quad (82) \]

but also

\[ [N, a_i^\dagger] = : \partial_{a_i} \exp(Q) : \]
\[ = : \left( \partial_{a_i} Q \right) \exp(Q) : \]
\[ = \left( \sum_j d_{ij}^{[2]} a_j^\dagger \right) N \quad \Leftrightarrow \quad \text{Eq. (79)} \quad (83) \]
This completes the proof. It is then not difficult to see that, inversely that any $H$ of the form

$$H = h_{ij} a_i^\dagger a_j$$

(84)

can be put into diagonal form $H_d$ by using the inverse of $N$ and adjusting the coefficient $c^{[1]}, d^{[1]}$ suitably. The $\mu$'s are the eigenvalues of the matrix constructed with the $h_{ij}$ which is supposed to be diagonalisable at this stage.

In particular for the case of $p = 2$, this can be read off directly for an arbitrary $H$ from formulas (6) (7) (8) (9) for the coefficient $c^{[1]}, d^{[1]}$ of Eq. (74).

Our arguments about the existence of a Hermitian Hamiltonian when the eigenvalues are real also applies to the infinite dimensional case. While we were concluding this article a paper by Mostafadazeh [9] appeared, demonstrating that a quantum mechanical anharmonic oscillator with potential $ix^3$ giving rise to a non-Hermitian Hamiltonian can be transformed to a Hermitian form, thus giving an alternative proof of the reality of energy eigenvalues.

## 9 Conclusions

The Landau problem of a particle in a magnetic field has been shown to demonstrate the phenomenon of a non-Hermitian Hamiltonian giving rise to real eigenvalues when the coupling to the magnetic field becomes pure imaginary has been exhibited. All properties of this model are explicitly calculable as it is really a free field theory in disguise, which illuminates the conditions under which non-Hermitian Hamiltonians may have real eigenvalues. Indeed, starting from real eigenvalues in a finite system, which is then subject to a similarity transform, it has been shown how to define creation and annihilation operators, and their conjugation to build a Fock space for a general non-Hermitian Hamiltonian. In all the cases that we have studied in detail, we have observed that, at least formally, when a non-Hermitian Hamiltonian possesses real eigenvalues, there exists a change of basis such that the transformed Hamiltonian in the corresponding subspace becomes Hermitian. Other properties of such systems have been discussed, notably the conditions for degenerate eigenvalues. In the $2 \times 2$ case and extensions thereof this is a sign that the associated matrix is not fully diagonalisable and marks the transition between real and complex conjugate pairs of eigenvalues.
