DARBOUX TRANSFORMATION FOR DIRAC EQUATIONS WITH (1 + 1) POTENTIALS

A V Yurov

Abstract. We study the Darboux transformation (DT) for Dirac equations with (1 + 1) potentials. Exact solutions for the adiabatic external field are constructed. The connection between the exactly soluble Dirac (1+1) potentials and the soliton solutions of the Davey–Stewartson equations is discussed.

1. INTRODUCTION.

The Darboux transformation (DT) is a convenient way to construct a rich set of integrable potentials of the steady–state Shrödinger equation in the single dimensional case [1]. As shown in [2], DT can be used to study the Dirac equation for a two–dimensional fermion in an external scalar field \( w(x) \). The aim of this work is the generalization of DT for the Dirac equations with one–space–dimensional and non–stationary potentials \( u(t, x) \). In Sec. 2 we show that for a fermion of transverse momenta \( p \equiv p_y, q \equiv p_z \) the four–dimensional equation reduces to the Zakharov–Shabat equation. We demonstrate DT for this equation and the connection with intertwining and supersymmetry algebra. The result of the multiple DT (extended Crum law [3]) is set forth in Sec. 3. In Sec. 4 we show the connection between the exactly solvable Dirac (1+1) potentials and the soliton solutions of the Davey–Stewartson equations [4]. We also discuss the reduction restriction problem.

2. DARBOUX TRANSFORMATION

Let us consider the four–dimensional Dirac equation

\[
(i\gamma^\mu \partial_\mu - \gamma^\mu A_\mu(t, x) + m)\Psi = 0.
\] (1)

We use the \( \gamma \)-matrix representation [2], [5]

\[
\gamma^0 = \begin{pmatrix} 0 & \sigma_2 \\ \sigma_2 & 0 \end{pmatrix}, \quad \gamma^1 = \begin{pmatrix} 0 & -i\sigma_1 \\ -i\sigma_1 & 0 \end{pmatrix},
\]

\[
\gamma^2 = \begin{pmatrix} -iI & 0 \\ 0 & iI \end{pmatrix}, \quad \gamma^3 = \begin{pmatrix} 0 & -i\sigma_3 \\ -i\sigma_3 & 0 \end{pmatrix},
\] (2)

and for \( A^\mu(t, x) \) we have either:

\[
A^\mu(t, x) = (0, 0, A^2(t, x), A^3(t, x))^T,
\] (3)

or

\[
A^\mu(t, x) = (0, 0, Q(t, x), cQ(t, x))^T, \quad c = \text{const}.
\] (4)
One can easily see that (3) and (4) are solutions of Maxwell equations. Let \( \Psi \) have the form:

\[
\Psi = \Phi(t, x) \exp(i(py + qz)), \quad Im p = Im q = 0.
\]  

(5)

Then \( \Phi \) satisfies the Zakharov–Shabat equation:

\[
\Phi_t = J \Phi_x + U \Phi.
\]  

(6)

For the case (3):

\[
U = \begin{pmatrix}
0 & \tilde{A} & 0 & m - \tilde{B} \\
\tilde{A} & 0 & \tilde{B} - m & 0 \\
0 & \tilde{B} + m & 0 & \tilde{A} \\
-\tilde{B} - m & 0 & \tilde{A} & 0
\end{pmatrix}, \quad J = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & -1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & -1
\end{pmatrix},
\]  

(7)

where \( \tilde{A} = i(A^3 - q) \), \( \tilde{B} = i(p - A^2) \).

For the case (4) we get:

\[
\Phi = \begin{pmatrix}
A \Gamma \\
B \Gamma
\end{pmatrix},
\]  

(8)

where

\[
A = \begin{pmatrix}
0 & \alpha \\
\mu & 0
\end{pmatrix}, \quad B = \begin{pmatrix}
0 & \beta \\
\mu \rho & 0
\end{pmatrix}, \quad \Gamma = \begin{pmatrix}
\psi(t, x) \\
\phi(t, x)
\end{pmatrix},
\]  

\[
c = \frac{i q (\alpha^2 + \beta^2) + 2 m \alpha \beta}{i p (\alpha^2 + \beta^2) + m (\alpha^2 - \beta^2)}, \quad \rho = \frac{i (\alpha p + \beta q) + \alpha m}{i (\alpha p - \beta q) + \beta m}.
\]  

(9)

The condition \( c^* = c \) gives us for \( \alpha \equiv \alpha_R + i \alpha_I, \beta \equiv \beta_R + i \beta_I \):

\[
\frac{\beta_I}{\alpha_I} = \frac{q \alpha_R - p \beta_R}{p \alpha_R + q \beta_R}, \quad (p \alpha_R + q \beta_R)^2 (\alpha_R^2 - \alpha_I^2 + \beta_R^2) - \alpha_I^2 (q \alpha_R - p \beta_R)^2 +
\]

\[
+ 2 m \alpha_I (\beta_R^2 + \alpha_R^2) (p \alpha_R + q \beta_R) = 0.
\]  

(10)

One of the nontrivial solutions of (10) is

\[
\beta_I = 0, \quad \beta_R = \frac{q \alpha_R}{p}, \quad \alpha_I \pm = \frac{\alpha_R}{p} (m \pm \sqrt{m^2 + p^2 + q^2}).
\]  

(11)

Substituting (8), (9) into (1) and taking (10) into account, we get a \( 2 \times 2 \) equation (6) for \( \Gamma \) where \( J = \sigma_3 \),

\[
U = \begin{pmatrix}
0 & u \\
v & 0
\end{pmatrix},
\]

\[
u(t, x) = \lambda_1 + \lambda_2 Q(t, x), \quad v(t, x) = \nu_1 + \nu_2 Q(t, x),
\]

\[
\lambda_1 = \frac{m \beta + i(q \alpha - p \beta)}{\mu}, \quad \lambda_2 = \frac{1}{\mu} \frac{(\alpha^2 + \beta^2)(q \alpha - p \beta - i m \beta)}{i p (\alpha^2 + \beta^2) + m (\alpha^2 - \beta^2)},
\]

\[
\nu_1 = \frac{\mu (m^2 + q^2 + p^2)}{i (p \beta - q \alpha) - m \beta}, \quad \nu_2 = \frac{i \mu \beta}{\beta (1 - c \rho)}.
\]  

(12)
Let \( \chi_1 \) and \( \chi_2 \) be \( 4 \times 4 \) (for the case (3)) or \( 2 \times 2 \) (for the case (4)) matrix solutions of equation (6). We define a matrix function \( \tau_1 \equiv \chi_{1,x} \chi_1^{-1} \). It easy to see that \( \tau_1 \) satisfies the following nonlinear equations:

\[
\tau_{1,t} = \sigma_3 \tau_{1,x} + [U, \tau_1] + [\sigma_3, \tau_1] + U_x. \tag{13}
\]

Equation (6) is covariant with respect to DT:

\[
\chi_2[1] = \chi_{2,x} - \tau_1 \chi_2, \quad U[1] = U + [\sigma_3, \tau_1]. \tag{14}
\]

It is necessary to choose the function \( \chi_1 \) in such a way that the structure of the matrix \( U[1] \) be the same as the structure of the matrix \( U \). This is the condition that we call the reduction restriction (see Sec.4).

The transformation (14) allows us to construct a superalgebra, in just the same way as the DT for the steady–state Shrödinger equation in a one–dimensional case [6]. In order to do this we introduce the following operators:

\[
G(+) = \frac{\partial}{\partial x} - \tau_1, \quad G(-) = \frac{\partial}{\partial x} + \tau_1^+. \tag{15}
\]

Let us define new several operators as follow:

\[
h \equiv G(-)G(+), \quad h[1] \equiv G(+)G(-), \tag{16}
\]

\[
T \equiv \frac{\partial}{\partial t} - J \frac{\partial}{\partial x} - U, \quad T[1] \equiv \frac{\partial}{\partial t} - J \frac{\partial}{\partial x} - U[1]. \tag{17}
\]

It easy to see that

\[
G(+)T = T[1]G(+), \quad TG(-) = G(-)T[1], \quad [h, T] = [h[1], T[1]] = 0. \tag{18}
\]

The operators \( h \) and \( h[1] \) are the tipical one–dimensional matrix Hamiltonians:

\[
h = \frac{\partial^2}{\partial x^2} + \rho_D \frac{\partial}{\partial x} + V, \quad h[1] = \frac{\partial^2}{\partial x^2} + \rho_D \frac{\partial}{\partial x} + V[1], \tag{19}
\]

\[
\rho_D = (\tau_1^+ - \tau_1)_D, \quad V = -(\tau_{1,x} + \tau_1^+ \tau_1), \quad V[1] = \tau_{1,x}^+ - \tau_1 \tau_1^+, \tag{20}
\]

where \((\tau_1)_D\) – diagonal part of \( \tau_1 \). It easy to see that the operators \( q(\pm) \), \( H \)

\[
q(+) = \begin{pmatrix} 0 & 0 \\ G(+) & 0 \end{pmatrix}, \quad q(-) = \begin{pmatrix} 0 & G(-) \\ 0 & 0 \end{pmatrix}, \quad H = \begin{pmatrix} h & 0 \\ 0 & h[1] \end{pmatrix} \tag{21}
\]

generate a supersymmetry algebra:

\[
\{q(\pm), q(\pm)\} = [q(\pm), H] = 0, \quad \{q(\pm), q(-)\} = H. \tag{22}
\]

Furthermore we restrict ourselves to studying the case (4). The case (3) will be considered in a separate work.

3. EXTENDED CRUM LAW
Let us consider $2N + 1$ particular solutions of (6) with $\Gamma_k \equiv (\psi_k, \phi_k)^T$, $k \leq 2N$, $\Phi \equiv (\psi, \phi)$:

$$\psi_{k,t} + \psi_{k,x} + u(t, x)\phi_k = 0, \quad \phi_{k,t} - \phi_{k,x} + v(t, x)\psi_k = 0. \quad (23)$$

The following theorem is established:

**THEOREM**

Functions $\psi[N], \phi[N]$ satisfy (23) with potentials $u[N]$ and $v[N]$ such that:

$$\psi[N] = \frac{\Delta_1}{D}, \quad \phi[N] = \frac{\Delta_2}{D}, \quad u[N] = u + 2\frac{D_1}{D}, \quad v[N] = v - 2\frac{D_2}{D}, \quad (24)$$

where $\Delta_{1,2}, D_{1,2}, D$ are the following determinants ($\psi^{(N)} \equiv \frac{\partial^N \psi(t, x)}{\partial x^N}$):

$$D = \begin{vmatrix}
\psi_1^{(N-1)} & \psi_1 & \phi_1^{(N-1)} & \phi_1 \\
\psi_2^{(N-1)} & \psi_2 & \phi_2^{(N-1)} & \phi_2 \\
\vdots & \vdots & \vdots & \vdots \\
\psi_{2N}^{(N-1)} & \psi_{2N} & \phi_{2N}^{(N-1)} & \phi_{2N}
\end{vmatrix},$$

$$D_1 = \begin{vmatrix}
\psi_1^{(N)} & \psi_1 & \phi_1^{(N-2)} & \phi_1 \\
\psi_2^{(N)} & \psi_2 & \phi_2^{(N-2)} & \phi_2 \\
\vdots & \vdots & \vdots & \vdots \\
\psi_{2N}^{(N)} & \psi_{2N} & \phi_{2N}^{(N-2)} & \phi_{2N}
\end{vmatrix},$$

$$D_2 = \begin{vmatrix}
\psi_1^{(N-2)} & \psi_1 & \phi_1^{(N)} & \phi_1 \\
\psi_2^{(N-2)} & \psi_2 & \phi_2^{(N)} & \phi_2 \\
\vdots & \vdots & \vdots & \vdots \\
\psi_{2N}^{(N-2)} & \psi_{2N} & \phi_{2N}^{(N)} & \phi_{2N}
\end{vmatrix},$$

$$\Delta_1 = \begin{vmatrix}
\psi_1^{(N)} & \psi_1 & \phi_1^{(N-1)} & \phi_1 \\
\psi_2^{(N)} & \psi_2 & \phi_2^{(N-1)} & \phi_2 \\
\vdots & \vdots & \vdots & \vdots \\
\psi_{2N}^{(N)} & \psi_{2N} & \phi_{2N}^{(N-1)} & \phi_{2N}
\end{vmatrix},$$

$$\Delta_2 = \begin{vmatrix}
\phi_k^{(N)} & \psi_k^{(N-1)} & \psi_k^{(N-1)} & \phi_k^{(N)} \\
\phi_k^{(N)} & \psi_k^{(N-1)} & \psi_k^{(N-1)} & \phi_k^{(N)} \\
\vdots & \vdots & \vdots & \vdots \\
\phi_k^{(N)} & \psi_k^{(N-1)} & \psi_k^{(N-1)} & \phi_k^{(N)}
\end{vmatrix}. \quad (24)$$

To prove this theorem we construct $N \times 2 \times 2$ matrix functions $\chi_k = (\Phi_{2k-1}, \Phi_{2k})$, $1 \leq k \leq N$:

$$\chi_k = \begin{pmatrix} \psi_{2k-1} & \psi_{2k} \\ \phi_{2k-1} & \phi_{2k} \end{pmatrix}.$$
These functions satisfy the matrix equation (6) with \( J = \sigma_3 \).

After N–time DT (14) we get \( \chi[N] \) and \( U[N] \) which satisfy (6). Let us write \( \chi[N] \) as a series:

\[
\chi[N] = \chi^{(N)} - \sum_{i=1}^{N} A_i(t,x)\chi^{(N-i)}, \quad A_i = \begin{pmatrix} a_i & b_i \\ c_i & d_i \end{pmatrix}.
\]  

(25)

Plugging (25) into (23) we get (here \( C^k_N = \frac{N!}{k!(N-k)!} \)):

\[
\sum_{k=0}^{N} C^k_N U^{(k)} \chi^{(N-k)} + \sum_{k=1}^{N} \left[(A_{k,t} - \sigma_3 A_{k,x})\chi^{(N-k)} - 2\sigma_3 (A_k)_{k} \chi^{(N-k+1)}\right] + \sum_{k=1}^{N} \sum_{i=0}^{N-k} C^i_N A_k U^{(i)} \chi^{(N-k-i)} - U[N](\chi^{(N)} + \sum_{k=1}^{N} A_k \chi^{(N-k)}) = 0,
\]  

(26)

where \( (A_k)_{k} \) is the off–diagonal part of \( A_k \). Therefore

\[
u[N] = u + 2b_1, \quad v[N] = v - 2c_1.
\]  

(27)

To compute \( b_1 \) and \( c_1 \) we take into account that \( \chi_k[N] = 0 \) if \( k \leq N \), therefore we get a system of 2N equations as follows:

\[
\psi_i^{(N)} = \sum_{n=1}^{N} (a_n \psi_i^{(N-n)} + b_n \phi_i^{(N-n)}), \quad \phi_i^{(N)} = \sum_{n=1}^{N} (c_n \psi_i^{(N-n)} + d_n \phi_i^{(N-n)}),
\]  

(28)

\( i = 1, \ldots, N \). Using Kramer’s formulae, we get (24).

If (see (12)) \( \mu = i(\beta^* - c\alpha^*)^{-1} \) then \( Im\nu_2 = Im\lambda_2 = 0 \). The constants \( \lambda_1 \) and \( \nu_1 \) may be annihilated by the standard gauge \( U(1) \) transformations. Using freedom in our choice of parameters, let us assume that \( v(t,x) = \kappa u(t,x) \), \( \kappa = \pm 1 \). Now we can supplement (24) with the transformations law for \( \chi_1 \) (\( N = 1 \)):

\[
\psi_1[1] = \frac{\phi_2}{\Delta}, \quad \psi_2[1] = \frac{\kappa \phi_1}{\Delta}, \quad \phi_1[1] = \frac{\kappa \psi_2}{\Delta},
\]

\[
\phi_2[1] = \frac{\psi_1}{\Delta}, \quad \Delta = \begin{vmatrix} \psi_1 & \psi_2 \\ \phi_1 & \phi_2 \end{vmatrix}.
\]  

(29)

It is necessary to require that after N–time DT the following reduction restriction will be true:

\[
v[N] = \kappa u[N].
\]  

(30)

In the general case we do not have an algorithm allowing us to keep (30) in all the steps of DT. However, it is possible by the introduction of the so called binary DT which allows one to preserve the reduction restriction (30) [7].

Let us consider a closed 1–form

\[
d\Omega = dx \zeta \chi + dt \zeta \sigma_3 \chi, \quad \Omega \equiv \int d\Omega
\]  

(31)

where a \( 2 \times 2 \) matrix function \( \zeta \) solves the equation:

\[
\zeta_t = \zeta_x \sigma_3 - \zeta U.
\]  

(32)
We shall apply the DT for (6). One can verify by immediate substitution that (32) is covariant with respect to the transform if
\[ \zeta[+1] = \Omega(\zeta, \chi) \chi^{-1}. \] (33)

Now we can alternatively affect \( U \), by the following transformation:
\[ U[+1, -1] = U + [\sigma_3, \chi \Omega^{-1} \zeta]. \] (34)

It may be shown that
\[ \chi[+N, -N] = \chi - \sum_{k=1}^{N} \theta_k \Omega(\zeta_k, \chi), \quad \zeta[+N, -N] = \zeta - \sum_{k=1}^{N} \Omega(\zeta, \chi_k) s_k, \] (35)
where \( \theta_k \) and \( s_k \) may be found from the following equations:
\[ \sum_{k=1}^{N} \theta_k \Omega(\zeta_k, \chi_i) = \chi_i, \quad \sum_{k=1}^{N} \Omega(\zeta_i, \chi_k) s_k = \zeta_i. \] (36)

The transformation:
\[ U[+N, -N] = U + \sum_{i,k=1}^{N} [\sigma_3, \theta_i \Omega(\zeta_k, \chi_i) s_k] \] (37)
is the forementioned binary DT.

Let \( v = \kappa u^* \) (see Sec. 4; in this section \( u \) and \( v \) are real so the condition is equivalent to (30)), then \( U[+N, -N] \) will satisfy the reduction restriction if we choose \( \zeta_k \) and \( \chi_k \) such that:
\[ \zeta_k = \chi_k R, \quad R = diag(1, -\kappa). \] (38)

The solution that follows from (34) has the form
\[ u[+1, -1] = u + \frac{2\kappa(\psi_2^* \phi_1^* \theta_{12} + \psi_1^* \phi_2^* \theta_{12} - \psi_1^* \phi_1^* \theta_{22} - \psi_2^* \phi_2^* \theta_{11})}{\theta_{11} \theta_{22} - |\theta_{12}|^2}, \] (39)
\[ \theta_{ik} = \int dx (\psi_i^* \psi_k - \kappa \phi_i^* \phi_k) + dt (\psi_i^* \psi_k + \kappa \phi_i^* \phi_k). \]

Note that the square of the absolute value \( u[+1, -1] \) is expressed by the compact formula:
\[ |u[+1, -1]|^2 = |u|^2 - \kappa(\frac{\partial^2}{\partial t^2} - \frac{\partial^2}{\partial x^2}) \ln(\theta_{11} \theta_{22} - |\theta_{12}|^2). \] (40)

DT allow us to construct a rich set of the exact solutions of the Dirac equations with \((1+1)\) potentials. In conclusion of this section we consider decreasing in \( t, x \to \pm \infty \) fields (adiabatic engaging and turning-off). Let \( u = v = 0 \). The particular solutions of (23) are:
\[ \psi_k = A_k e^{\omega(t-x)} + B_k e^{\omega(x-t)}, \quad \phi_k = C_k e^{\lambda(t+x)} + D_k e^{-\lambda(t+x)}, \] (41)
where \( k = 1, 2; A, B, C, D, \omega \) and \( \lambda \) are real constants. After DT (14) under condition (12) we get:
\[ Q(t, x) = \frac{1}{\mu_1 \cosh(at + bx + \delta_1) + \mu_2 \cosh(bt + ax + \delta_2)}, \] (42)
\[u(t, x) = \xi Q(t, x), \quad v(t, x) = -\frac{1 + c^2}{\xi^2} u(t, x),\]  

(43)

\[\xi = |\alpha c - \beta|^2 = 4\omega(A_1B_2 - A_2B_1), \quad a = \omega + \lambda, \quad b = \lambda - \omega, \quad \mu(\beta^* - c\alpha^*) = i,\]

\[1 + c^2 = 4\lambda \xi (C_2D_1 - C_1D_2), \quad \omega(A_1B_2 - A_2B_1) = \lambda(D_1C_2 - D_2C_1),\]

\[\mu_1 = \sqrt{(A_1C_2 - A_2C_1)(B_1D_2 - B_2D_1)}, \quad \mu_2 = \sqrt{(B_1C_2 - B_2C_1)(A_1D_2 - A_2D_1)},\]

\[\delta_1 = \frac{1}{2} \ln \frac{A_1C_2 - A_2C_1}{B_1D_2 - B_2D_1}, \quad \delta_2 = \frac{1}{2} \ln \frac{B_1C_2 - B_2C_1}{A_1D_2 - A_2D_1},\]

where \(\alpha, \beta\) satisfy (11). The potential (42) is a localized impulse, which decreases in \(t \to \pm \infty\). A particular solution of the Dirac equation may be calculated using (5), (8) from \((\psi_{1,2}[1], \phi_{1,2}[1])^T\), where \(\psi_{1,2}[1]\) and \(\phi_{1,2}[1]\) are defined by (29). This bispinor describes the quazi–stationary state of a fermion. The fermion is free along the \(y\) and \(z\) and restrained along the \(x\)-axis.

4. DAVEY-STEWARTSON EQUATIONS.

It is shown in [2] that a class of the exactly soluble Dirac one–dimensional potentials corresponds to a soliton solutions of the MKdV equation, just as certain Schrödinger potentials are solutions of the KdV equation. In this section we show that there exist the analogous connection between exactly soluble Dirac (1+1) potentials and soliton solutions of the Davey–Stewartson equations (DS).

The DS equations appear as the commutation condition of the two operators [7], [8]:

\[[T_1, T_2] = 0,\]

(44)

where \(T_1 \equiv T\) (see (17)) and \(T_2\) is given by the formula:

\[T_2 = i \frac{\partial}{\partial y} + 2\sigma_3 \frac{\partial^2}{\partial x^2} + 2U \frac{\partial}{\partial x} + U_x + \sigma_3 U_t + A,\]

(45)

\[A = \text{diag}(A_1, A_2), \quad v = \kappa u^*,\]

\[A_1 = -\kappa |u|^2 + \frac{1}{2i} l(+) F, \quad A_2 = \kappa |u|^2 + \frac{1}{2i} l(−) F.\]

Here \(l(\pm) = \frac{\partial}{\partial x} \pm \frac{\partial}{\partial y}\) and \(F\) is a pure imaginary function. The operator \(T_2\) is also covariant with respect to DT, what allows one to get infinite sets of exact solutions of DS, for example soliton solutions, exponentially localized on the plane – the dromions (42) [7], [8]. The DS equations contain two fields: \(u(y, t, x)\) – the amplitude wavetrain function and \(S(y, t, x) \equiv -iF_x\) – the amplitude function of slowly changing in \(t\) (space variable!) and \(x\) mean field:

\[iu_y + u_{xx} + u_{tt} - 2\kappa |u|^2 u + Su = 0, \quad l(+) l(−) S = -4\kappa (|u|^2)_{xx}.\]

(46)

The dromions \(S\)-component is constant along the two orthogonal directions and moves with the constant velocity [8].

In Sec.3 we have shown that the one–dromion solution corresponds to adiabatic engaging and turning-off electro-magnetic field. Boity, Leon, Martina and Pempinelli [8] showed that two dromions scatter against each other with the soliton phase shift, therefore the N–dromions solution corresponds to a adiabatic external field, too. A many–dromion solution may be obtained by the N–time DT. For this purpose we transform the \(LA\)-pair \((T_1\) and \(T_2\).
Introducing new variables \( x = p + q \) and \( t = p - q \) we exclude a field \( F \) from (45). The matrix \( A \) takes the form

\[
A = \begin{pmatrix}
\kappa \int_{-\infty}^{q} dq \frac{\partial |u|^2}{\partial p} + g_1(p, y) & 0 \\
0 & \kappa \int_{-\infty}^{p} dp \frac{\partial |u|^2}{\partial q} + g_2(q, y)
\end{pmatrix},
\]

where \( g_1(p, y) \) and \( g_2(q, y) \) are arbitrary functions. We suppose that \( u(p, q, y) \) belongs to a Schwarz space \( L \). Then a nonlocal flow is given as follows:

\[
S = 2\kappa |u|^2 + (\int_{-\infty}^{q} dq \frac{\partial}{\partial p} + \int_{-\infty}^{p} dp \frac{\partial}{\partial q}) |u|^2 + g_1 - g_2.
\]

In the new variables

\[
T_1 = \begin{pmatrix}
-\frac{\partial}{\partial q} & u \\
\kappa u^* & \frac{\partial}{\partial p}
\end{pmatrix},
\]

therefore for \( u \in L \), the equation \( T_1 \chi = 0 \) gives at infinity for components of \( \chi \) the following condition:

\[
\psi_k = \psi_k(p, y), \quad \phi_k = \phi_k(q, y), \quad k = 1, 2.
\]

The second equation \( T_2 \chi = 0 \) gives four nonstationary one-dimensional Schrödinger equations

\[
\begin{align*}
i\psi_{k,y} + \frac{1}{2} \psi_{k,pp} + v_1 \psi_k &= 0 \\
i\phi_{k,y} - \frac{1}{2} \phi_{k,qq} + v_2 \phi_k &= 0
\end{align*}
\]

where

\[
\begin{align*}
v_1(p, y) &= g_1 + \kappa \int_{-\infty}^{+\infty} dq \frac{\partial |u|^2}{\partial p}, \\
v_2(q, y) &= g_2 + \kappa \int_{-\infty}^{+\infty} dp \frac{\partial |u|^2}{\partial q}.
\end{align*}
\]

For the case of a dromion (42) we have

\[
\begin{align*}
v_1 &= 4\omega^2 \sec^2 f_1, \\
v_2 &= -4\lambda^2 \sec^2 f_2, \\
f_1 &= 2\omega(p - 2ay) + \frac{1}{2} \ln \frac{A_0}{b_0}, \\
f_2 &= 2\lambda(q + 2by) + \frac{1}{2} \ln \frac{C_0}{D_0},
\end{align*}
\]

where \( a, b, (A, B, C, D) \) are real constants. So the dromion sits on two plane solitons that correspond to the one-level reflectionless potentials. They may be easily obtained by the standard DT for the Schrödinger equation [1] on zero background:

\[
\begin{align*}
\psi_k[1] &= \frac{\partial \psi_k}{\partial p} \psi_0 - \frac{\partial \psi_0}{\partial p} \psi_k, \\
\phi_k[1] &= \frac{\partial \phi_k}{\partial q} \phi_0 - \frac{\partial \phi_0}{\partial q} \phi_k, \\
v_1[1] &= -2 \frac{\partial^2}{\partial p^2} \ln \psi_0, \\
v_2[1] &= 2 \frac{\partial^2}{\partial q^2} \ln \phi_0.
\end{align*}
\]

The background eigenfunctions are chosen such that:

\[
\psi_0(p, y) = 2\sqrt{A_0 B_0} \cosh f_1 e^{i\theta},
\]

\[
\phi_0(q, y) = \sqrt{C_0 D_0} \cosh f_2 e^{i\theta}.
\]
\[
\phi_0(q, y) = 2\sqrt{C_0D_0} \cosh f_2 e^{i\vartheta},
\]
where
\[
\theta = 2[(\omega^2 - a^2)y + a\varphi], \quad \vartheta = 2[(b^2 - \lambda^2)y + bq],
\]
and the new coefficients \((A, B, C, D)_0\) satisfy the conditions:
\[
A_0(B_1C_2 - B_2C_1) = B_0(A_1C_2 - A_2C_1), \quad C_0(A_1D_2 - A_2D_1) = D_0(B_1C_2 - B_2C_1).
\]

For the second DT it is necessary to switch to the two–level potentials in equations (51), (52). Let \(\omega > \varphi, \varphi > \lambda\) then two “linearly independent” solutions that correspond to the eigenvalues 2\(\varphi\) and 2\(\varphi\) have the form:
\[
\psi_{-1}^{(+) = A_{-1} e^{2\varphi(p-2\omega y)+i\theta_{-1}}, \quad \psi_{-1}^{(-} = B_{-1} e^{-2\varphi(p-2\omega y)+i\theta_{-1}}
\]
for (51) and
\[
\phi_{-1}^{(+) = C_{-1} e^{2\varphi(q+2\beta y)+i\theta_{-1}}, \quad \phi_{-1}^{(-} = D_{-1} e^{-2\varphi(q+2\beta y)+i\theta_{-1}}
\]
for (52), where \(\theta_{-1} \) and \(\vartheta_{-1} \) differ from \(\theta \) and \(\vartheta \) by substitution \((a, b, \lambda, \omega) \rightarrow (\alpha, \beta, \varphi, \varphi)\). We transform \(\psi_{-1}^{(\pm)} \) and \(\phi_{-1}^{(\pm)} \) by the formula (55) with \(\psi_0 \) and \(\phi_0 \) accordingly. Then we will build the new support function:
\[
\psi_{-1}[1] = \psi_{-1}^{(+1} - \psi_{-1}^{(-1}, \quad \phi_{-1}[1] = \phi_{-1}^{(+1} - \phi_{-1}^{(-1}.
\]
For simplicity let us choose \(A = B = C = D = 1\). As a result we have:
\[
\psi_{-1}[1] = \left(\frac{(\omega - \omega) \cosh(\xi_0 + \xi_1) + (\omega + \omega) \cosh(\xi_0 - \xi_1)}{\cosh \xi_0} + i(\alpha - a) \sinh \xi_0 e^{i\theta_{-1}}\right),
\]
\[
\phi_{-1}[1] = \left(\frac{(\varphi - \varphi) \cosh(\eta_0 + \eta_1) + (\varphi + \varphi) \cosh(\eta_0 - \eta_1)}{\cosh \eta_0} + i(\beta - b) \sinh \eta_0 e^{i\theta_{-1}}\right)
\]
where \(\xi_0 = 2\omega(p-2\omega y), \xi_1 = 2\omega(p-2\omega y), \eta_0 = 2\lambda(q+2by), \eta_1 = 2\varphi(q+2by).\) If one puts \(\alpha = a, \beta = b\) then (62), (63) exactly coincide with the supporting functions that generate the two–level potential with respect to the Darboux transformations [8].

Now it is necessary to define four functions \(\psi_k[1], \phi_k[1] (k = 1, 2)\) which are the solutions of (51), (52) with the potentials (54). The basic problem at this step is the independence of the wronskians
\[
\left| \begin{array}{cc}
\frac{\partial \psi_2}{\partial p} & \frac{\partial \psi_1}{\partial p} \\
\frac{\partial \psi_2}{\partial \varphi} & \frac{\partial \psi_1}{\partial \varphi}
\end{array} \right|,
\]
\[
\left| \begin{array}{cc}
\frac{\partial \phi_2}{\partial q} & \frac{\partial \phi_1}{\partial q} \\
\frac{\partial \phi_2}{\partial \varphi} & \frac{\partial \phi_1}{\partial \varphi}
\end{array} \right|
\]
with respect to the space coordinates, what is necessary for the solvability of the reduction restriction equation \(v[2] = \kappa u^*[2]\). For this purpose it is enough to choose:
\[
\psi_k[1] = A_{k,-1}(\omega - \omega \tanh \xi_0)\psi_{-1}^{(+) + B_{k,-1}(\omega + \omega \tanh \xi_0)\psi_{-1}^{(-}},
\]
\[
\phi_k[1] = C_{k,-1}(\varphi - \varphi \tanh \eta_0)\phi_{-1}^{(+) + D_{k,-1}(\varphi + \varphi \tanh \eta_0)\phi_{-1}^{(-}}
\]
with the constants that satisfy the relation:
\[
\varphi(\omega^2 - \omega^2)(B_{1,-1}A_{2,-1} - B_{2,-1}A_{1,-1}) = \kappa \varphi(\lambda^2 - \varphi^2)(C_{1,-1}D_{2,-1} - C_{2,-1}D_{1,-1}).
\]
Therefore we choose \(\psi_{-2}[2], \phi_{-2}[2]\) as the wave functions that generate a three–level potential (via DT) and determine the corresponding functions \(\psi_k[2] \) and \(\phi_k[2].\) One may repeat this procedure and realize the third DT.

ACKNOWLEDGMENTS

The author would like to express his cordial thanks to M. Rudnev for his attention to this work and for valuable discussion. This work was partially sponsored by the RFFI under Grant No. 91-01-01789.
