Abstract

We propose a new basis in Witten’s open string field theory, in which the star product simplifies considerably. For a convenient choice of gauge the classical string field equation of motion yields straightforwardly an exact analytic solution that represents the nonperturbative tachyon vacuum. The solution is given in terms of Bernoulli numbers and the equation of motion can be viewed as novel Euler–Ramanujan-type identity. It turns out that the solution is the Euler–Maclaurin asymptotic expansion of a sum over wedge states with certain insertions. This new form is fully regular from the point of view of level truncation. By computing the energy difference between the perturbative and nonperturbative vacua, we prove analytically Sen’s first conjecture.

1 Introduction

Despite the beauty and simplicity of Witten’s covariant field theory [1] for open bosonic string, only limited progress has been achieved over the years in practical applications [2, 3]. The two main successes of the theory are computations of certain perturbative string amplitudes and understanding the phenomenon of tachyon condensation. It is fair to say nonetheless, that off-shell amplitudes in the Siegel gauge, the most popular covariant gauge, are rather unwieldy for practical purposes. To find explicitly even the simplest off-shell amplitudes, one has to resort to numerical methods. For the tachyon condensation the situation is not much better. Putting aside the interesting vacuum string field theory proposal [4], most of the results so far were obtained by tedious numerical computations, following the seminal work of Sen and Zwiebach [5], using the method of level truncation [6].

The physics of tachyon condensation\(^1\) has made a major step forward when Ashoke Sen identified the open-string tachyon with a physical instability of the D-brane on which the open string ends. He made the following three conjectures [11, 12]. First, he related the height of the tachyon potential at the true minimum to the tension of the D-brane on which the tachyon lives. Second, he predicted existence of lump solutions with correct tensions which describe lower dimensional D-branes popping out of the true vacuum. Finally he conjectured that there are no physical excitations around the minimum and hence the cohomology of the BRST-like kinetic operator there is empty. Sen’s conjectures have been tested in variety of models, such as noncommutative field theory, \(p\)-adic string, boundary string field theory or vacuum string field theory. Within boundary string field theory the first and second conjectures were proved in [13, 14, 15]. The third conjecture is true by construction in the vacuum string field theory and the first two conjectures in this model were proved in [16, 17, 18].

The most accurate, beautiful and complete formulation of open bosonic string field theory is Witten’s cubic string field theory, but unfortunately due to the lack of exact analytic solutions, it allowed Sen’s conjectures to be tested only numerically. The height of the tachyon potential has been tested with ever increasing accuracy in [5, 19, 20]. The second conjecture was tested in a number of interesting papers starting with [21, 22, 23] and the third one in [24, 25, 26]. For more references we refer to the reviews [2, 3] and [27, 28, 29, 30].

There was a large effort towards constructing analytic solutions. Various exact symmetries of the Siegel-gauge solution have been identified [31, 32, 33] and other were actively looked for [34]. Exact solutions were sought in the pure-gauge-like or partial-isometry form advocated in [35], but so far all such explicit solutions [36, 37, 38] contained the identity state of the string field algebra with some insertions and turned out to be singular. There was another class of papers [39, 40, 41], which attempted to find systematic analytic approximations to the exact solutions.

\(^1\) Some early papers on this issue include [7, 8, 9, 10].
Unfortunately none of the above papers succeeded in proving Sen’s conjectures perhaps with the exception of the third conjecture [42, 43, 44]. It is the goal of the present paper to provide the first nonsingular solution and prove Sen’s first conjecture.

The reason why most computations are hard in string field theory is twofold. First is that the three-string vertex itself
\[ \langle V_{123}||\psi_1\rangle \otimes |\psi_2\rangle \otimes |\psi_3\rangle, \]
which defines the product in the string field algebra \(|\psi_1| * |\psi_2||V_{123}\rangle\), is quite complicated, especially when expressed in the standard basis of \(L_0\) eigenstates formed by matter and ghost oscillators. There is a basis in which the star product simplifies [45, 46, 47, 48, 49], but manifest background independence in the tachyon sector is lost and also conformal field theory techniques become rather cumbersome.

The second reason that makes all the computations even harder is the choice of gauge fixing. Imposing the Siegel gauge \(b_0\psi = 0\) results in the propagator \(b_0/L_0\). Now every non-trivial string field theory amplitude contains as part of its expression\(^2\)
\[ |\psi_1\rangle \ast \frac{b_0}{L_0} \left( |\psi_2\rangle \ast |\psi_3\rangle \right). \tag{1.1} \]

These building blocks of the string field theory Feynman diagrams have never been worked out explicitly, but it is clear that they can be extracted from general off-shell amplitudes that have been obtained in the past, and that they are going to depend on Schwarz–Christoffel maps of polygons to the unit disk. Typically the parameters specifying the map depend on propagator lengths (i.e. the Schwinger parameters) in a rather transcendental way [50, 51, 52, 53].

The string world-sheet is usually parameterized by a complex strip coordinate \(w = \sigma + i\tau\), \(\sigma \in [0, \pi]\) or by \(z = -e^{-i\sigma} = -e^{-i\sigma+\tau}\), which takes values in the upper half-plane. As has been shown in [16], the gluing conditions entering the geometrical definition of the star product simplify if one uses another coordinate \(\tilde{z} = \arctan z\), in which the upper half-plane looks as a semi-infinite cylinder of circumference \(\pi\). In fact, in this coordinate we can write down simple closed form expression for arbitrary star products within the subalgebra generated by Fock space states. Elements of this subalgebra are finite sums of the so called wedge states with insertions [54, 55], which we shall write in the form
\[ U_r^{\dagger} U_r \tilde{\phi}_1(\tilde{x}_1) \tilde{\phi}_2(\tilde{x}_2) \ldots \tilde{\phi}_n(\tilde{x}_n)|0\rangle. \tag{1.2} \]

By \(\tilde{\phi}(\tilde{x})\) we denote a local operator \(\phi(z)\) expressed in the \(\tilde{z}\) coordinate, which in the special case of a primary field of dimension \(h\) is given by
\[ \tilde{\phi}(\tilde{z}) = \left( \frac{dz}{d\tilde{z}} \right)^h \phi(z) = (\cos \tilde{z})^{-2h} \phi(\tan \tilde{z}). \tag{1.3} \]

\(^2\)For certain amplitudes one does not need the full information about the star product [51]. For example for the 4-point amplitude we need only the contraction \(\langle \psi_1| * (|\psi_2| \frac{b_0}{L_0} |\psi_3\rangle) = \langle I| |\psi_1\rangle * |\psi_2\rangle * \frac{b_0}{L_0} (|\psi_3\rangle * |\psi_4\rangle)\).
The operator $U_r$ is a scaling operator in the $\tilde{z}$ coordinate, which can be written as $U_r = \left(\frac{\tilde{z}}{r}\right)^{L_0}$, where

$$L_0 = \oint \frac{dz}{2\pi i} \tilde{z} T_{\tilde{z}\tilde{z}}(\tilde{z})$$

is the zero mode of the worldsheet energy momentum tensor $T_{\tilde{z}\tilde{z}}$ in the $\tilde{z}$ coordinate. By a conformal transformation it can be expressed as

$$L_0 = \oint dz \frac{2}{\pi i} \left(1 + z^2\right) \arctan z T_{zz}(z) = L_0 + \sum_{k=1}^{\infty} \frac{2(-1)^{k+1}}{4k^2 - 1} L_{2k},$$

where the $L_n$’s are the ordinary Virasoro generators with zero central charge $c = 0$ of the total (i.e. matter and ghost) conformal field theory. The operator $U_r^\dagger$ in (1.2) is hermitian conjugate of $U_r$, which in our particular case coincides with the BPZ conjugate.\(^3\)

At first glance it might look surprising that we write (1.2) with the factor $U_r^\dagger U_r$ and not simply $U_r^\dagger$. After all, $U_r$ is just a scaling operator and its action on conformal fields of dimension $h$ is particularly simple

$$U_r \tilde{\phi}(\tilde{z}) U_r^{-1} = \left(\frac{2}{r}\right)^h \tilde{\phi} \left(\frac{2}{r} \tilde{z}\right),$$

and it also keeps the vacuum invariant $U_r |0\rangle = |0\rangle$. There are at least two reasons why we write (1.2) the way we write it. The first reason is that the star product of two such states takes a very simple form

$$U_r^\dagger U_r \tilde{\phi}(\tilde{x}) |0\rangle \ast U_r^\dagger U_s \tilde{\psi}(\tilde{y}) |0\rangle = U_r^\dagger r+s-1 U_{r+s-1} \tilde{\phi}\left(\tilde{x} + \frac{\pi}{4} (s - 1)\right) \tilde{\psi}\left(\tilde{y} - \frac{\pi}{4} (r - 1)\right) |0\rangle,$$

where if there were more insertions, all insertions from the first string field would be shifted by $\pi(s - 1)/4$, whereas those from the second string field would move by $-\pi(r - 1)/4$. We shall give a detailed derivation of this formula in section 2 although it follows easily from a similar expression in [55]. A nice feature of (1.7) is, that it is valid for any local operator insertions, not necessarily primary fields. Second reason for writing our states in the form (1.2) will become clear later, when we discuss expansion of the string field in the $L_0$ eigenstates.

A well known special case of (1.2) are the wedge states $|r\rangle \equiv U_r^\dagger |0\rangle$ of Rastelli and Zwiebach [54]. They have no operator insertions (one can view it as an insertion of the operator identity) and by virtue of (1.7) they obey the simple algebra

$$|r\rangle \ast |s\rangle = |r + s - 1\rangle.$$

This family of states is pretty rich by itself, since it contains the identity string field $|I\rangle = |1\rangle$ of the star algebra, the $SL(2,\mathbb{R})$ invariant vacuum $|0\rangle$ somewhat confusingly being the wedge

\(^3\)Recall that the hermitian conjugate for a holomorphic field of dimension $h$ is $\phi_n^\dagger = \phi_{-n}$, whereas the BPZ conjugate is $\text{bpz}(\phi_n) = (-1)^{n+h} \phi_{-n}$. \(\Box\)
state \( |2⟩ \), multiple products of the vacua
\[
|n⟩ = |0⟩ \ast |0⟩ \ast \ldots \ast |0⟩ = U_n^\dagger |0⟩ = \left( \frac{2}{n} \right)^n |0⟩,
\]
(n-1) times
and finally it contains a peculiar projector \( |∞⟩ \) called the sliver.

Given the simplicity of the star product (1.7) in the \( \tilde{z} \) coordinate one may hope to be able to solve analytically the classical string field equation of motion \( Q_B \Psi + \Psi \ast \Psi = 0 \) coming from Witten’s action
\[
S = -\frac{1}{g^2} \left[ \frac{1}{2} \langle \Psi, Q_B \Psi \rangle + \frac{1}{3} \langle \Psi, \Psi \ast \Psi \rangle \right].
\]
(1.10)
Beautiful aspect of this action is its enormous gauge invariance \( \delta \Psi = Q_B \Lambda + \Psi \ast \Lambda - \Lambda \ast \Psi \) which, however, has to be fixed in one way or another unless one wants to deal with the full gauge orbit. The most popular choice for gauge fixing has been the Siegel gauge \( b_0 \Psi = 0 \). But alas, applying \( b_0/L_0 \) to the both sides of the equation of motion, one finds
\[
\Psi + \frac{b_0}{L_0} (\Psi \ast \Psi) = 0,
\]
which cannot be solved easily within the states of the form (1.2), since application of the propagator \( b_0/L_0 = b_0 \int_{t=0}^{∞} e^{-tL_0} \) leaves the family of wedge states with insertions. For this very reason also the off-shell amplitudes in Siegel gauge are doomed to be rather complicated.

We are thus led to look for other gauge choices. Most natural one, and as far as we can tell, the only one that works, is obtained by replacing the Siegel gauge \( b_0 \Psi = 0 \) with \( B_0 \Psi = 0 \), where \( B_0 \) is the zero mode of the \( b \) ghost in the \( \tilde{z} \) coordinate
\[
B_0 = \oint \frac{dz}{2\pi i} \tilde{z} b_{zz}(\tilde{z}) = \int \frac{dz}{2\pi i} (1 + z^2) \arctan z b_{zz}(z) = b_0 + \sum_{k=1}^{∞} \frac{2(-1)^{k+1}}{4k^2 - 1} b_{2k}.
\]
(1.12)
Its anticommutator with the BRST charge \( Q_B \) is \( \{ Q_B, B_0 \} = L_0 \) and hence, multiplying the equation of motion with \( B_0/L_0 \), which itself is part of the propagator,\(^4\) we can write analogously to (1.11) the ‘projected’ equation of motion as
\[
\Psi + \frac{B_0}{L_0} (\Psi \ast \Psi) = 0.
\]
(1.13)

It turns out that the operators \( L_0 \) and \( L_0^\dagger \) obey a very simple algebra
\[
\left[ L_0, L_0^\dagger \right] = L_0 + L_0^\dagger,
\]
(1.14)
\(^4\)Actually, as we shall discuss elsewhere, the propagator in our gauge is equal to \( \frac{b_0}{L_0} Q_B \frac{b_0^\dagger}{L_0^\dagger} \). Apparently the presence of two Schwinger parameters for each propagator is the only disadvantage of our gauge. Note that the propagator in the Siegel gauge can be written in a similar form since \( \frac{b_0}{L_0} = \frac{b_0}{L_0} Q_B \frac{b_0}{L_0^\dagger} \).
and the algebra beautifully extends when generators $B_0, B_0^\dagger, B_1 = b_1 + b_{-1}$ and $K_1 = L_1 + L_{-1}$ are added to it. The Lie algebra \eqref{eq:1.14} can be exponentiated and we find a Lie group with the property

\[
x \mathcal{L}_0 y \mathcal{L}_0 = \left( \frac{y}{x+y-x} \right) \mathcal{L}_0^\dagger \left( \frac{x}{x+y-x} \right) \mathcal{L}_0,
\]

which has a natural interpretation in terms of gluing of surfaces \cite{55}. This relation allows for easy application of $B_0/L_0$ to a product of several Fock states of the form \eqref{eq:1.2}. For the wedge states for example, we find

\[
\frac{B_0}{L_0} |r\rangle = -B_0^\dagger \int \frac{ds}{x} |s\rangle,
\]

which apart of the $B_0^\dagger$ factor is a superposition of states of the form \eqref{eq:1.2}. Enlarging our algebra of wedge states with insertions \eqref{eq:1.2} by allowing for the explicit appearance of $B_0^\dagger$, we find a simple sector of the star algebra closed not only under the star product, but also under the action of the BRST charge $Q_B$, the semi-propagator $B_0/L_0$ and many other operators.

The only method that has so far been used successfully for solving the string field theory equation of motion in Siegel gauge is the level truncation \cite{6}. Essentially one expands the string field in the eigenstates of the $L_0$ operator and truncates it to the first few levels, hoping that this presents a good approximation for the physical problem in question. This method has been very successful in finding the nonperturbative tachyon vacuum of the open strings \cite{5,19,20}.

As we have seen, the star algebra tremendously simplifies if one uses the $\tilde{z}$ coordinate. This leads us immediately to the possibility that the $L_0$ level truncation might be the more natural one for string field theory. It turns out that states of the form \eqref{eq:1.2} have very simple expansion in terms of the $L_0$ eigenstates. Unlike in the $L_0$ basis, where $U_r$ is rather complicated, in the $L_0$ basis the combination $U_r^\dagger U_r$ is equal to

\[
U_r^\dagger U_r = \sum_{n=0}^{\infty} \frac{1}{n!} \left( \frac{2-r}{2} \right)^n \widehat{L}^n, \quad \widehat{L} \equiv L_0 + L_0^\dagger.
\]

By \eqref{eq:1.14} we see that the $n$-th term is an eigenstate (under the adjoint action) of $L_0$ with eigenvalue $n$. Similarly, also the local operators in \eqref{eq:1.2} can be naturally expanded in the basis of $L_0$ eigenstates. For example for the ghost field we have

\[
\tilde{c}(\tilde{z}) = \sum_{n=-\infty}^{\infty} \tilde{c}_n \tilde{z}^{n-1},
\]

where $\tilde{c}_n$ are $L_0$ eigenstates with eigenvalue $n$.

One rather unexpected feature arises when we combine the $B_0$ gauge with the $L_0$ level truncation in certain sector of the theory (formed by the $\tilde{c}_n$ modes, and $\widehat{L}$ and $\widehat{B} \equiv B_0 + B_0^\dagger$ operators acting on the vacuum). The entire set of equations of motion for the individual
components of $Q_B \Psi + \Psi \ast \Psi = 0$ acquires such a simple structure, that they can be solved exactly by a simple recursive procedure, level by level. The outcome of such a calculation is surprisingly so simple, that a full all-levels form can be easily guessed to be

$$
\Psi = \sum_{n=0}^{\infty} \sum_{p=-1}^{n} \frac{\pi^p}{2^{n+2p+1}n!} (-1)^n B_{n+p+1} \hat{\mathcal{L}}^n \bar{c}_{-p} |0\rangle + \sum_{n=0}^{\infty} \sum_{p,q=-1}^{p+q \text{ odd}} \frac{\pi^{p+q}}{2^{n+2(p+q)+3}n!} (-1)^{n+p+q+2} B_{n+p+q+2} \hat{B} \hat{\mathcal{L}}^n \bar{c}_{-p} \bar{c}_{-q} |0\rangle,
$$

(1.19)

where $B_n$ are the Bernoulli numbers; see appendix B for the definition and few basic properties.

Although a direct attempt to express the solution (1.19) in the conventional $L_0$ basis gives rise to a divergent series, it turns out that (1.19) is the Euler–Maclaurin asymptotic expansion of the following sum over wedge states with insertions

$$
\Psi = \lim_{N \to \infty} \left[ \psi_N - \sum_{n=0}^{N} \partial_n \psi_n \right],
$$

(1.20)

$$
\psi_n = \frac{2}{\pi} U_{n+2}^\dagger U_{n+2} \left[ \hat{\mathcal{B}} \hat{c} \left( -\frac{\pi}{4} n \right) \hat{c} \left( \frac{\pi}{4} n \right) + \frac{\pi}{2} \left( \hat{c} \left( -\frac{\pi}{4} n \right) + \hat{c} \left( \frac{\pi}{4} n \right) \right) \right] |0\rangle.
$$

(1.21)

As is well known, in most cases the Euler–Maclaurin series are badly divergent (although they are often Borel summable as is the case here), so we should not be surprised by the divergence.

For the re-summed form (1.20), we prove that the solution is a true solution of the equation of motion, and we give a fully analytic proof of Sen’s first conjecture. This new form is also suitable for the decomposition into the $L_0$ eigenstates. We find numerically that the coefficients are well behaved, higher level coefficients seem to decay quite rapidly, and the solution resembles many features of the Siegel gauge solution [5, 19, 20]. This is in fact a rather pleasing feature of our gauge. Just as $\tan x \simeq x$ for small $x$, we have $\mathcal{B}_0 = b_0 + \frac{3}{4} b_2 + \cdots$ and it seems that the dominant effect of the gauge fixing comes from the $b_0$ part.\(^5\) Also truncating our exact solution to finite $L_0$ levels, gives us a good approximation to the energy. Third way at arriving at the right energy is to start with the solution in the $L_0$ basis and use Padé approximants. By this method one confirms Sen’s first conjecture with accuracy about $10^{-6}$ at level 18.

The paper is organized as follows. In section 2 we will review and further develop properties of the star product using the $\hat{z}$ coordinate. We will also prove a simple but powerful lemma, which will later allow direct construction of the tachyon vacuum. In section 3 we will solve a simple toy model equation $(L_0 - 1) \Phi + \Phi \ast \Phi = 0$ whose solution will be given in terms of

\(^5\)This proximity to the Siegel gauge distinguishes our $\mathcal{B}_0$ gauge from another interesting old proposal [56] which uses the star algebra derivative $\mathcal{B}_1 = b_1 + b_{-1}$. The $\mathcal{B}_0$ gauge shares some of the nice algebraic properties with the $\mathcal{B}_0$ gauge, but it seems to fail in describing the tachyon condensation.
Bernoulli numbers. The equation of motion will become rather elegant and novel identity for the Bernoulli numbers, somewhat akin to the Euler–Ramanujan identities. This example will serve a useful lesson for the true string field theory with ghost number one string field in section 4. Here we shall describe how to find the solution and provide an alternative form useful for proving Sen’s first conjecture, which we explicitly prove. Apart of the analytic proof we provide two other rather distinct numerical confirmations, one using the Padé approximants and another one using ordinary level truncation. Some details are left for the appendices.

2 Star algebra

2.1 The Fock space and the two-vertex

The string field theory star algebra is an algebra built on the Hilbert space of the first quantized string. Postponing questions about its completeness, such a space must contain the Fock space, which we define here as the set of states created from the vacuum by the action of finitely many creation operators, or equivalently by the insertion of local operators in the far past being represented by the puncture $P$ on the worldsheet, see Fig. 1.

Figure 1: String worldsheet in three different coordinate systems related by $z = -e^{-i w}$ and $\tilde{z} = \arctan z$. In the $\tilde{z}$ coordinate the lines marked with an arrow are identified, so that the worldsheet forms semi-infinite cylinder $C_\pi$. Fock states are given by the insertion of local operators at the puncture $P$. Inserting operators also at $\tau = +\infty$, i.e. $z = \infty$ or $\tilde{z} = -\pi/2 = \pi/2 \mod \pi$ would correspond to taking the BPZ inner product. We have also marked the left and right (looking backwards in time) parts of the string at $\tau = 0$ separated by the midpoint $M$.

Traditionally two coordinate systems have been used most often. The first, the more intuitive one, uses worldsheet time $\tau \in (-\infty, \infty)$ and coordinate $\sigma \in [0, \pi]$ which are often combined to form a new complex coordinate $w = \sigma + i \tau$ defined on a strip. Second coordinate system obtained by the map $z = -e^{-i w}$ is the most practical one for conformal field theory computations, since correlation functions on the upper half-plane are easily found by the method of images.
For the purposes of string field theory a third coordinate system is the most useful one. It is obtained by the map \( \tilde{z} = \arctan z \) which takes the upper half-plane (UHP) into the semi-infinite cylinder \( C_\pi \) with circumference \( \pi \). The conformal field theory in this coordinate remains easy. As in the case of the upper half-plane, one can also employ the doubling trick to restrict our attention to a single holomorphic sector only. General \( n \)-point functions on \( C_\pi \) can be readily found in terms of correlators on the upper half-plane by conformal mapping.\(^6\)

\[
\langle \phi_1(\tilde{x}_1) \cdots \phi_n(\tilde{x}_n) \rangle_{C_\pi} = \langle \tilde{\phi}_1(\tilde{x}_1) \cdots \tilde{\phi}_n(\tilde{x}_n) \rangle_{UHP}.
\]

(2.1)

The fields \( \tilde{\phi}_i(\tilde{x}_i) \) were defined in [103] as a coordinate change (i.e. a passive conformal transformation) of \( \phi_i(x_i) \). Alternatively they can be expressed as an active conformal transformation \( \tilde{\phi}_i(\tilde{x}_i) = \tan \circ \phi_i(x_i) \), where in general \( f \circ \mathcal{O} \) denotes an active conformal transformation of the operator \( \mathcal{O} \). If, for example, \( \mathcal{O} \) is a primary field \( \phi(x) \) of dimension \( h \), then \( f \circ \phi(x) = (f'(x))^h \phi(f(x)) \). As we shall discuss below, the active conformal transformation can be represented by a similarity transformation on the string Hilbert space \( f \circ \mathcal{O} = U_f \mathcal{O} U_f^{-1} \).

Consider for example the two and three-point functions. Let \( \tilde{\phi}_i(z) \) be appropriately normalized holomorphic primary fields of dimension \( h_i \). Then the standard correlators in the upper half-plane

\[
\langle \phi_i(x)\phi_j(y) \rangle_{UHP} = \frac{\delta_{ij}}{(x-y)^{2h_i}},
\]

(2.2)

\[
\langle \phi_i(x)\phi_j(y)\phi_k(z) \rangle_{UHP} = \frac{C_{ijk}}{(x-y)^{h_i+h_j-h_k}(x-z)^{h_i+h_k-h_j}(y-z)^{h_j+h_k-h_i}}
\]

(2.3)

readily imply

\[
\langle \tilde{\phi}_i(\tilde{x})\tilde{\phi}_j(\tilde{y}) \rangle_{C_\pi} = \frac{\delta_{ij}}{\sin(\tilde{x}-\tilde{y})^{2h_i}},
\]

(2.4)

\[
\langle \tilde{\phi}_i(\tilde{x})\tilde{\phi}_j(\tilde{y})\tilde{\phi}_k(\tilde{z}) \rangle_{C_\pi} = \frac{C_{ijk}}{\sin(\tilde{x}-\tilde{y})^{h_i+h_j-h_k}\sin(\tilde{x}-\tilde{z})^{h_i+h_k-h_j}\sin(\tilde{y}-\tilde{z})^{h_j+h_k-h_i}}
\]

(2.5)

on the semi-infinite cylinder \( C_\pi \). The correlators are indeed well defined on \( C_\pi \), as they are invariant under a shift of any of the coordinates by \( \pi \), e.g. \( x \rightarrow x + \pi \), provided that all dimensions \( h_i \) are integer valued. Also note that the leading short distance behavior is the same for \( C_\pi \) and \( UHP \), as it should be.

As we have already mentioned, the Fock states are defined by insertions of local operators in the far past on the world-sheet

\[
|\phi \rangle = \phi(0)|0\rangle.
\]

(2.6)

\(^6\)In the modern language of string field theory [53] [16] one uses a global coordinate \( z \) defined on the upper half-plane and local coordinates defined around punctures. In that approach one never needs to discuss explicitly correlators anywhere else than in the upper half-plane. It helps our intuition however, to introduce at intermediate stages correlators of local operators on ‘real’ cylinders, even though in practise they are evaluated by mapping them to the upper half-plane. Care must be taken when translating formulas from one formalism to another. We thank Barton Zwiebach for a discussion that helped clarify this issue.
But unless we are considering states corresponding to insertions of primary operators (on-shell states for example), the states depend on the coordinate system used to insert the local operators. From the string field theory point of view, it is more natural to work with states

\[ |\tilde{\phi}\rangle = |\tilde{\phi}(0)\rangle|0\rangle \]  

created from the vacuum by the insertion of \( \phi(0) \) in the \( \tilde{z} \) coordinate. By conformal transformation this state can be expressed as

\[ |\tilde{\phi}\rangle = U_{\tan}|\phi\rangle = e^{\frac{1}{3}L_2 - \frac{1}{24}L_4 + \frac{11}{1800}L_6 - \frac{1}{1200}L_8 - \frac{11}{46770}L_{10} + \cdots} |\phi\rangle, \]  

where \( U_{\tan} \) is an operator which represents the action of conformal transformation \( \tilde{z} \rightarrow z = \tan \tilde{z} \) and can be explicitly constructed following [58, 54], see also [55]. Note that \( U_{\tan} \) is the inverse of \( U_{\arctan} \) which is used to define the sliver state [54].

In general, for any conformal map \( f(z) \) holomorphic at \( z = 0 \) one can construct the operator \( U_f \) as an exponential \( \exp(\sum v_n L_n) \), where \( n \geq 0 \) and \( v_n \) are Laurent coefficients of a vector field \( v(z) = \sum v_n z^{n+1} \) related to the map \( f(z) \) by the Julia equation \( v(z)\partial_z f(z) = v(f(z)) \). We should mention however, that the vector field \( v(z) \) often exists only as a formal power series, i.e. with zero radius of convergence. This is the case for \( f(z) = \tan z \) and \( f(z) = \arctan z \), (whose generating vector fields differ by an overall minus sign) as was shown in [55].

One of the key ingredients of string field theory is the two-vertex, which is the familiar BPZ inner product of conformal field theory, see Fig. 1. It is defined as a map \( \mathcal{H} \otimes \mathcal{H} \rightarrow \mathbb{R} \)

\[ \langle \phi_1, \phi_2 \rangle = \langle I \circ \phi_1(0) \phi_2(0) \rangle_{UHP}, \]  

where \( I : z \rightarrow -1/z \) is the inversion symmetry. For the states \( |\tilde{\phi}_i\rangle \) the two-vertex can be written as

\[ \langle \tilde{\phi}_1, \tilde{\phi}_2 \rangle = \langle I \circ \phi_1(0) \phi_2(0) \rangle_{UHP} = \langle \phi_1 \left( \frac{\pi}{2} \right) \phi_2(0) \rangle_{C_{\pi}}. \]  

Note that in the \( \tilde{z} \) coordinate the inversion symmetry \( I : z \rightarrow -1/z \) becomes just a translation (i.e. a rotation) along the circumference \( I : \tilde{z} \rightarrow \tilde{z} \pm \pi/2 \). The correlators (2.4) and (2.5) on \( C_{\pi} \) are manifestly invariant under it.

### 2.2 The three-vertex and the star product

Unlike in closed string field theory [59], in open string field theory there is a single vertex which determines all the interactions. The three-vertex is a map \( \mathcal{H} \otimes \mathcal{H} \otimes \mathcal{H} \rightarrow \mathbb{R} \) and is defined as a correlator on a surface formed by gluing together three strips representing three open string worldsheets, see Fig. 2.

Traditionally [57, 54], for states \( |\phi_i\rangle \) defined using the \( z \) coordinate, the three-vertex has been written as

\[ \langle \phi_1, \phi_2, \phi_3 \rangle = \langle f_1 \circ \phi_1(0) f_2 \circ \phi_2(0) f_3 \circ \phi_3(0) \rangle_{UHP}, \]  

(2.11)
where \( f_n(z) = \tan\left(\frac{(2-n)\pi}{3} + \frac{2}{3} \arctan z\right) \). For states defined using the \( \tilde{z} \) coordinate it can be expressed directly as

\[
\langle \tilde{\phi}_1, \tilde{\phi}_2, \tilde{\phi}_3 \rangle = \langle \phi_1 \left( \frac{\pi}{2} \right) \phi_2(0) \phi_3 \left( -\frac{\pi}{2} \right) \rangle_{C_{3\pi/2}},
\]

without the need of any conformal map. Here the correlator is taken on a semi-infinite cylinder \( C_{3\pi/2} \) of circumference \( 3\pi/2 \), see Fig. 2.

The three-vertex allows us to introduce the star product \(*: \mathcal{H} \otimes \mathcal{H} \to \mathcal{H}\). Given two states \( |\phi_1\rangle \) and \( |\phi_2\rangle \) the star product is defined by matching the three-vertex with an additional ‘test state’ \( |\chi\rangle \) to the two-vertex

\[
\langle \tilde{\chi}, \tilde{\phi}_1, \tilde{\phi}_2 \rangle = \langle \tilde{\chi}, \tilde{\phi}_1 * \tilde{\phi}_2 \rangle, \quad \forall \chi.
\]

Graphically the star product of two Fock states can be represented by the surface in Fig. 3. To find an explicit formula for the star product it is useful to rewrite the left hand side of (2.13) as a correlator on a semi-infinite cylinder \( C_{\pi} \) of circumference \( \pi \)

\[
\langle \tilde{\chi}, \tilde{\phi}_1, \tilde{\phi}_2 \rangle = \langle s \circ \chi \left( \pm \frac{3\pi}{4} \right) s \circ \phi_1 \left( \frac{\pi}{4} \right) s \circ \phi_2 \left( -\frac{\pi}{4} \right) \rangle_{C_{\pi}}.
\]

using a simple conformal map \( s: \tilde{z} \to \frac{2}{3} \tilde{z} \). Note that the scaling transformation \( s \) is implemented by \( U_3 \equiv (2/3)\mathcal{L}_0 \), where \( \mathcal{L}_0 \) was introduced in (1.4) and (1.5). Thinking of \( s \circ \phi_1 \left( \frac{\pi}{4} \right) s \circ \phi_2 \left( -\frac{\pi}{4} \right) \) in terms of its local operator product expansion around \( \tilde{z} = 0 \), the right hand side of (2.14) has the form of the two-vertex (2.10). To see it more clearly, let us restrict to the set of test states \( \chi \) with definite scaling dimension \( h \). Then indeed \( s \circ \chi(\pm 3\pi/4) = (2/3)^h \chi(\pm \pi/2) \). Writing thus (2.14) as the two-vertex, the factor \((2/3)^h\) can be traded for an operator \( U_3^\dagger \) acting on the second entry \( s \circ \phi_1 \left( \frac{\pi}{4} \right) s \circ \phi_2 \left( -\frac{\pi}{4} \right) \), so that we have

\[
\langle \tilde{\chi}, \tilde{\phi}_1, \tilde{\phi}_2 \rangle = \langle \tilde{\chi}, U_3^\dagger \left( s \circ \phi_1 \left( \frac{\pi}{4} \right) s \circ \phi_2 \left( -\frac{\pi}{4} \right) \right) \rangle
\]
Figure 3: Star product of two states $|\tilde{\phi}_1 \rangle \ast |\tilde{\phi}_2 \rangle$ represented by local operator insertions at punctures $P_1$ and $P_2$. A local operator $\chi$ corresponding to the ‘test state’ $|\tilde{\chi} \rangle$ can be inserted at the puncture $P_3$. The correlator is evaluated on a semi-infinite cylinder of circumference $3\pi/2$.

and hence we find

$$\tilde{\phi}_1(0)|0\rangle \ast \tilde{\phi}_2(0)|0\rangle = U_3^\dagger U_3 \tilde{\phi}_1 \left( \frac{\pi}{4} \right) \tilde{\phi}_2 \left( -\frac{\pi}{4} \right) |0\rangle.$$  \hspace{1cm} (2.16)

When the local fields $\phi_{1,2}$ are, for example, primary fields of conformal dimensions $h_{1,2}$ we can use the fact that $U_r$ has a simple action \(^1\) on them, and we can re-express (2.16) in the standard form

$$\phi_1(0)|0\rangle \ast \phi_2(0)|0\rangle = \left( \frac{8}{9} \right)^{h_1+h_2} U_3^\dagger \phi_1 \left( \tan \frac{\pi}{6} \right) \phi_2 \left( -\tan \frac{\pi}{6} \right) |0\rangle.$$  \hspace{1cm} (2.17)

This formula agrees with few explicit examples given in \[54\] and generalized in \[55\]. It will be however formula (2.16), and its generalizations given in the next subsection, that will be most useful for the rest of the paper.

Let us now explain how to translate the expression (2.16) to the ordinary Virasoro basis based on the coordinate $z$. By Virasoro basis we essentially mean the basis in the Verma module formed by the action of matter or total Virasoro generators on the highest weight states. In general the operator $U_r \equiv (2/r) L_0$ represents the scaling $\tilde{z} \rightarrow \frac{2}{r} \tilde{z}$, which in the $z$ coordinate becomes $z \rightarrow f_r(z)$, where

$$f_r(z) = \tan \left( \frac{2}{r} \arctan z \right).$$  \hspace{1cm} (2.18)

The operators $U_r$ can be written as $\exp(\sum v_n L_n)$, by solving recursively the Julia equation $v(z) \partial_z f_r(z) = v(f_r(z))$ following \[54\]. One finds

$$U_r = \left( \frac{2}{r} \right)^L_0 e^{-\frac{2}{3} r^2 L_2} \frac{L_4}{1560 r^6} \left( \frac{176+128 r^2+11 r^4}{16} \right) L_6 \frac{\left( r^2+4 \right) \left( r^2+1+14 r^2 \right)}{1260 r^8} L_8 \cdots.$$  \hspace{1cm} (2.19)

Using the composition rule $U_f \circ \circ \circ U_g = U_f U_g$ which reflects the fact that $U_f$ form a representation
of the conformal group, one can arrive to a more convenient canonically ordered form\(^7\)
\[
U_r = \left( \frac{2}{r} \right) \frac{L_0}{3^{2} r} \frac{L_2}{4^{4} r} L_4 e^{-16(r^2-4)(r^2-1)(r^2+5)} L_6 e^{(r^2-4)(109r^4+436r^4-944r^4+1344)} \frac{L_8}{1340 r^8} \cdots,
\]
which is advantageous in level truncation computations. The least ordered, but most beautiful
form of \(U_r\) is of course the one already mentioned
\[
U_r = \left( \frac{2}{r} \right) L_0 e^{\log\left( \frac{2}{r} \right) L_0 + \frac{2}{3} L_2 - \frac{2}{15} L_4 + \frac{2}{35} L_6 - \frac{2}{63} L_8 + \cdots}.
\]

2.3 Wedge states with insertions

So far we have considered only a star product of two Fock states. Generalization to the multiple
star product \(|\tilde{\phi}_1\rangle \ast |\tilde{\phi}_2\rangle \ast \cdots \ast |\tilde{\phi}_n\rangle\), where \(|\tilde{\phi}_j\rangle \equiv \tilde{\phi}_j(0)|0\rangle\), is rather straightforward and is obtained
by gluing together \(n+1\) strips as in Fig. 4. The analog of \((2.16)\) is
\[
|\tilde{\phi}_1\rangle \ast |\tilde{\phi}_2\rangle \ast \cdots \ast |\tilde{\phi}_n\rangle = e^{\log\left( \frac{2}{r} \right) (L_0 + \frac{2}{3} L_2 - \frac{2}{15} L_4 + \frac{2}{35} L_6 - \frac{2}{63} L_8 + \cdots)} \prod_{i=1}^{n} \tilde{\phi}_i(\tilde{x}_i)|0\rangle.
\]

Figure 4: Multiple star product \(|\tilde{\phi}_1\rangle \ast |\tilde{\phi}_2\rangle \ast \cdots \ast |\tilde{\phi}_n\rangle\), the so called wedge state with insertions. Without
insertions it would be denoted as \(|n+1\rangle\). The correlator is evaluated on a semi-infinite cylinder of
circumference \((n+1)\pi/2\).

\[
|\tilde{\phi}_1\rangle \ast |\tilde{\phi}_2\rangle \ast \cdots \ast |\tilde{\phi}_n\rangle = U_{n+1}^\dagger U_{n+1} \tilde{\phi}_1 \left( \frac{n-1}{4} \pi \right) \tilde{\phi}_2 \left( \frac{n-3}{4} \pi \right) \cdots \tilde{\phi}_n \left( - \frac{(n-1)}{4} \pi \right) |0\rangle.
\]

In more generality we could consider a family of states
\[
U_{n+1}^\dagger U_{n+1} \tilde{\phi}_1(\tilde{x}_1) \tilde{\phi}_2(\tilde{x}_2) \cdots \tilde{\phi}_n(\tilde{x}_n)|0\rangle,
\]
for arbitrary real \(r \geq 1\) and arbitrary insertion points \(\tilde{x}_i\), \(|\text{Re} \tilde{x}_i| \leq (r-1)\pi/4\). How do such
states star multiply? States of the form \((2.23)\) are represented by cylinders of circumference
\(rn\pi/2\) and punctures at points \(\tilde{x}_i\) as in Fig. 4 regardless of whether they can be constructed by

\(^7\)It is easy to write a simple recursive algorithm similar to the one of [54] to find out the coefficients in front
of \(L_n\) for almost arbitrarily high \(n\). We provide more details in appendix A.
gluing Fock states or not. The star multiplication proceeds as for Fock states by simply gluing together the parts of the two or more cylinders with strips of length $\pi/2$ cut out (in light yellow on Fig. 4), and then gluing back one such strip to form a new bigger cylinder. Mathematically we can write it as

$$U_t^\dagger U_r \phi_1(x_1) \ldots \phi_n(x_n)|0\rangle = U_t^\dagger U_s \psi_1(y_1) \ldots \psi_m(y_m)|0\rangle = U_t^\dagger U_r \phi_1(x_1 + \frac{\pi}{4}(r - 1)) \ldots \phi_n(x_n + \frac{\pi}{4}(s - 1)) \psi_1(y_1 - \frac{\pi}{4}(r - 1)) \ldots \psi_m(y_m - \frac{\pi}{4}(s - 1))|0\rangle,$$

where $t = r + s - 1$. We leave it as an exercise to the reader to check the associativity.

Before we end this discussion let us look in more detail on the simplest case with no insertions, i.e. when all operators $\phi_i$ are taken to be the identity operator. These are the original wedge states $|r\rangle = U_t^\dagger U_r |0\rangle = U_t^\dagger |0\rangle$ introduced by Rastelli and Zwiebach in [54]. They obey a simple algebra

$$|r\rangle * |s\rangle = |r + s - 1\rangle,$$

which is a special case of (2.24). Note that the SL(2,R) invariant vacuum $|0\rangle$ is the wedge state $|2\rangle$. The wedge state $|r\rangle$ with lowest allowed $r = 1$ is the identity of the star algebra. For the limiting value $r \to \infty$ one finds a projector, so called sliver state which has attracted much attention in the literature, especially in the context of the vacuum string field theory [4].

### 2.4 Operator algebra in the $\tilde{z}$ coordinate

To tackle such a complicated task such as solving the string field equations of motion, we found it very useful to use an operator formalism and to algebraize the problem. In fact our formula (2.24) was a first step in this program. Let us now take a few steps further.

We have already noted that the wedge states can be naturally written in terms of the (hermitian or BPZ conjugate) of the scaling operator $U_r = (2/r)^L_0$. The infinitesimal generator of the scaling is given by the zero mode $L_0$ of the total energy momentum tensor $T_{\tilde{z}\tilde{z}}(\tilde{z})$ with zero central charge. Let us now look at other modes. We define

$$L_n = \oint \frac{d\tilde{z}}{2\pi i} \tilde{z}^{n+1} T_{\tilde{z}\tilde{z}}(\tilde{z}) = \oint \frac{dz}{2\pi i} (1 + z^2) (\arctan z)^n T_{zz}(z).$$

Note that there would be a central charge contribution in the last equation if $c$ were nonzero. The hermitian conjugate is then given by

$$L_m^\dagger = \oint \frac{dz}{2\pi i} (1 + z^2) (\arccot z)^m T_{zz}(z).$$

*Note that under star multiplication the circumference can only grow, or in a limiting case with $r = 1$ can remain the same. Having $r < 1$ would formally correspond to deleting a part of surface, it is hard to make sense of it in case there are some punctures, and it is also ill behaved in level truncation [55].
Both sets of operators obey standard Virasoro algebra with zero central charge.

\[
\begin{align*}
[\mathcal{L}_n, \mathcal{L}_m] &= (n-m)\mathcal{L}_{n+m}, \\
[\mathcal{L}_n^\dagger, \mathcal{L}_m^\dagger] &= -(n-m)\mathcal{L}_{n+m}^\dagger.
\end{align*}
\]  

(2.29) (2.30)

What about the mixed commutators? It turns out that three operators \( \mathcal{L}_0, \mathcal{L}_0^\dagger \) and \( \mathcal{L}_{-1} = K_1 \equiv L_1 + L_{-1} \), which will be of particular importance, form an interesting closed algebra \[55, 60\]

\[
\begin{align*}
[\mathcal{L}_0, \mathcal{L}_0^\dagger] &= \mathcal{L}_0 + \mathcal{L}_0^\dagger, \\
[\mathcal{L}_0, K_1] &= K_1, \\
[\mathcal{L}_0^\dagger, K_1] &= -K_1.
\end{align*}
\]  

(2.31) (2.32) (2.33)

There are three different ways of deriving it. The first, the most straightforward way, is to use the explicit form (1.5)

\[
\mathcal{L}_0 = \ell_0 + \sum_{k=1}^\infty \frac{2(-1)^{k+1}}{4k^2 - 1} L_{2k}
\]

and simply calculate the commutators as we did in [55]. The second, rather indirect way is to use the gluing theorem to argue [55] that

\[
U_r U_s^\dagger = U_{2+\frac{2}{s}(s-2)} U_{2+\frac{2}{r}(r-2)}
\]

(2.34)

Differentiating with respect to \( r \) and \( s \) and setting \( r = s = 2 \) one recovers [281]. The third method, which is also applicable for general modes \( \mathcal{L}_n \) is to use standard contour arguments\(^9\) to find

\[
[\mathcal{L}_n, \mathcal{L}_m^\dagger] = \oint \frac{dz}{2\pi i} (1 + z^2) (\arctan z)^n (\arccot z)^m ((m+1) \arctan z + (n+1) \arccot z) T(z)
\]

(2.35)

There is an important subtlety however, in that the contours must pass precisely through the points \( \pm i \); one can take the unit circle for example. The reason is that because of the cuts in \( \arctan z \), the contour in (2.27) must cross the imaginary axis within the segment \([-i, i]\), whereas the contour in (2.28) must cross it outside this range. The choice of operator ordering is determined by the time ordering (i.e. the \(|z|\)-ordering in the radial quantization) in the path integral formalism, and therefore to make sense of the operator product \( \mathcal{L}_0 \mathcal{L}_0^\dagger \) in the path integral, the contour defining \( \mathcal{L}_0^\dagger \) must lie inside the one defining \( \mathcal{L}_0 \). To satisfy these two conflicting requirements the contours must pass through points \( \pm i \), which are fortunately integrable singularities. This would not be the case for commutators \( [\mathcal{L}_r, O^\dagger] \), if \( O \) were an operator of dimension \( h \leq 0 \).

\(^9\) I thank Ian Ellwood for suggesting the method.
Some other nontrivial examples, which can be obtained by this method are

$$\left[ L_1, L_1^\dagger \right] = \frac{\pi^2}{6} (L_0 + L_0^\dagger) - \frac{2}{3} (L_2 + L_2^\dagger),$$  \hspace{1cm} (2.36)

$$\left[ L_0, L_1^\dagger \right] = \frac{\pi^2}{4} L_{-1} - L_1. \hspace{1cm} (2.37)$$

It is interesting to note that in general $\left[ L_n, L_m^\dagger \right]$ are given as finite linear combinations of the generators $L_k$ and $L_k^\dagger$ as long as $n, m \geq -1$.

In terms of ordinary Virasoro operators our new Virasoro operators are given explicitly by

$$L_2 = L_2 - \frac{1}{15} L_6 + \frac{64}{945} L_8 + \cdots$$

$$L_1 = L_1 + \frac{1}{3} L_3 - \frac{7}{45} L_5 + \frac{29}{315} L_7 + \cdots$$

$$L_0 = L_0 + \frac{2}{3} L_2 - \frac{2}{15} L_4 + \frac{2}{35} L_6 + \cdots$$

$$L_{-1} = L_{-1} + L_1. \hspace{1cm} (2.38)$$

$$L_{-2} = L_{-2} + \frac{4}{3} L_0 + \frac{11}{45} L_2 - \frac{8}{189} L_4 + \cdots$$

$$L_{-3} = L_{-3} + \frac{5}{3} L_{-1} + \frac{3}{5} L_1 - \frac{31}{945} L_3 + \cdots$$

$$L_{-4} = L_{-4} + 2 L_{-2} + \frac{16}{15} L_0 + \frac{62}{945} L_2 - \frac{1}{225} L_4 + \cdots.$$

Note that the operators $L_1, L_0, L_{-1}, L_{-2} \ldots$ are conservation laws for the sliver [61]. To see that, we note that $L_n$ defined in \ref{2.27} can be alternatively written as a conformal transformation of $L_n$

$$L_n = U_{\tan} L_n U_{\tan}^{-1} = \tan \circ L_n = \oint \frac{dz}{2\pi i} z^{n+1} \tan \circ T_{zz}(z) \hspace{1cm} (2.39)$$

and hence

$$\langle \infty | L_{-n} = 0 | U_{\arctan} L_n U_{\arctan}^{-1} = 0 | L_{-n} U_{\arctan} z = 0 \rangle (2.40)$$

for $n \geq -1$. We shall say more on the conservation laws for wedge states in appendix A.

Attentive reader might have noticed from \ref{2.31} that the combination $L_0 + L_0^\dagger$ commutes with $K_1$. In fact there is a deeper reason for that. Note that from \ref{2.27} and \ref{2.28}

$$L_0 + L_0^\dagger = \oint \frac{dz}{2\pi i} (1 + z^2) (\arctan z + \arccot z) T(z) \hspace{1cm} (2.41)$$

and

$$= \frac{\pi}{2} \oint \frac{dz}{2\pi i} (1 + z^2) \varepsilon(\text{Re } z) T(z), \hspace{1cm} (2.42)$$

\footnote{Had we worked with nonzero central charge, the only modification would be an additional term $c/6$ in $L_{-2}$. Nevertheless, as shown in [65] some commutators such as $[L_0, L_0^\dagger]$ would become divergent.}
where \( \varepsilon(x) \) is the step function equal to \( \pm 1 \) for positive or negative values respectively. (We also abbreviate \( T_{zz}(z) \) to \( T(z) \).) In order to be able to write expression (2.41) for both terms using a single contour integral, we have used the unit circle in both (2.27) and (2.28). Splitting the integration contour into two halves in (2.42), one in the \( \text{Re } z > 0 \) half-plane and the other in \( \text{Re } z < 0 \), we observe that these two semi-circle contour integrals are in fact the definition of \( K_1^L \) and \( K_1^R \) respectively. We thus find

\[
\mathcal{L}_0 + \mathcal{L}_0^\dagger = \frac{\pi}{2} \left( K_1^L - K_1^R \right),
\]

and since \( K_1^L + K_1^R = K_1 \), we also have

\[
K_1^L = \frac{1}{2} K_1 + \frac{1}{\pi} \left( \mathcal{L}_0 + \mathcal{L}_0^\dagger \right),
\]

\[
K_1^R = \frac{1}{2} K_1 - \frac{1}{\pi} \left( \mathcal{L}_0 + \mathcal{L}_0^\dagger \right).
\]

Now we see that the relation \( \left[ \mathcal{L}_0 + \mathcal{L}_0^\dagger, K_1 \right] = 0 \) is responsible for \( \left[ K_1^L, K_1^R \right] = 0 \). Here we are quite lucky, since such commutators between the left and right string operators are often anomalous.

The operators \( K_1^L, K_1^R \) and \( K_1 \) also have rather simple properties with regard to the star product

\[
K_1^L (\phi_1 \ast \phi_2) = (K_1^L \phi_1) \ast \phi_2; \quad (2.46)
\]

\[
K_1^R (\phi_1 \ast \phi_2) = \phi_1 \ast (K_1^R \phi_2); \quad (2.47)
\]

\[
K_1 (\phi_1 \ast \phi_2) = (K_1 \phi_1) \ast \phi_2 + \phi_1 \ast (K_1 \phi_2). \quad (2.48)
\]

The first two relations reflect the geometry of the Witten vertex, in that the left part of the first string becomes the left part of the product and the right part of the right string becomes the right part of the star product. The last relation is the well known fact that \( K_1 \) is a derivation of the star product. Sometimes an analogous relation might also be useful

\[
D (\phi_1 \ast \phi_2) = (D \phi_1) \ast \phi_2 + \phi_1 \ast (D \phi_2), \quad (2.49)
\]

where \( D = \mathcal{L}_0 - \mathcal{L}_0^\dagger \) is another star algebra derivative. The operators \( K_1^L \) and \( K_1^R \) play a further role, in that their operator action generates star multiplication by the family of wedge states for the full Hilbert space. Explicitly, as follows readily from the results in [55], we find

\[
|n\rangle \ast |\psi\rangle = e^{-(n-1)\frac{\pi}{2} K_1^L} |\psi\rangle, \quad (2.50)
\]

\[
|\psi\rangle \ast |n\rangle = e^{-(n-1)\frac{\pi}{2} K_1^R} |\psi\rangle. \quad (2.51)
\]

One can thus alternatively write the wedge states as\(^{11}\)

\[
|n\rangle = e^{-(n-2)\frac{\pi}{2} K_1^L}|0\rangle = e^{(n-2)\frac{\pi}{2} K_1^R}|0\rangle = e^{-(n-2)\frac{\pi}{2}} \left( K_1^L - K_1^R \right)|0\rangle = e^{-\frac{n-2}{2} \left( \mathcal{L}_0 + \mathcal{L}_0^\dagger \right)} |0\rangle. \quad (2.52)
\]

\(^{11}\)One could also write the wedge states as \( |n\rangle = e^{-(n-1)\frac{\pi}{2} K_1^L} |1\rangle \), which is reminiscent of the formal considerations in [22].
Number of interesting relations can be obtained by exponentiating the Lie algebra (2.31). The most important ones are

\[
U_r U_s = U_{rs},
\]

(2.53)

\[
U_r U_s^\dagger = U_{2+\frac{2}{r}(s-2)} U_{2+\frac{2}{r}(r-2)},
\]

(2.54)

\[
U_r e^{aX} = e^{2aX} U_r, \quad \text{valid for } X = K_1, K_1^{L,R}, L_0 + L_0^\dagger,
\]

(2.55)

\[
e^\beta (L_0 + L_0^\dagger) = U_{2-2\beta} U_{2-2\beta}.
\]

(2.56)

The first two were derived in [55], the latter two can be obtained by similar methods. Let us illustrate such a derivation on (2.56) which plays a central role in this paper. Let us denote \( f(x) = x^L_0 x^{L_0^\dagger}. \) Clearly \( f(1) = 1. \) The derivative \( f'(x) \) can be easily computed with the help of (2.57) given below

\[
f'(x) = \frac{1}{x} x^L_0 \left( L_0^\dagger + L_0 \right) x^{L_0^\dagger} = \frac{1}{x^2} f(x) \left( L_0^\dagger + L_0 \right) = \frac{1}{x^2} \left( L_0^\dagger + L_0 \right) f(x).
\]

Integrating this as a differential equation we find \( f(x) = \exp \left[ \left( 1 - \frac{1}{x} \right) \left( L_0^\dagger + L_0 \right) \right] \) and (2.56) readily follows.\(^{12} \) Other useful identities are

\[
U_r L_0^\dagger U_r^{-1} = -\frac{2-r}{r} L_0 + \frac{2}{r} L_0^\dagger,
\]

\[
U_r^{-1} L_0 U_r^\dagger = \frac{2}{r} L_0 + \frac{2-r}{r} L_0^\dagger,
\]

\[
U_r^{-1} L_0^\dagger U_r = \frac{r}{2} L_0 + \frac{r-2}{2} L_0^\dagger,
\]

\[
U_r^\dagger L_0 U_r^{-1} = \frac{r}{2} L_0 + \frac{r-2}{2} L_0^\dagger.
\]

(2.57)

Finally for completeness we remind the reader that on a primary field \( \tilde{\phi} \) of dimension \( h \) the exponentiated generators \( L_0 \) and \( K_1 \) act as scaling and translation

\[
\lambda L_0 \tilde{\phi}(\tilde{z}) \lambda^{-L_0} = \lambda^h \tilde{\phi}(\lambda \tilde{z}),
\]

(2.58)

\[
e^{\alpha K_1} \tilde{\phi}(\tilde{z}) e^{-\alpha K_1} = \tilde{\phi}(\tilde{z} + \alpha).
\]

(2.59)

### 2.5 Star product in the \( L_0 \)-basis

It turns out that the most general string field algebra elements (2.23) we have considered so far can be very naturally expressed in the basis of \( L_0 \) eigenstates. To start with, consider first pure wedge states with no insertions. They can be written using (2.57) as

\[
|r\rangle = U_r^\dagger U_r |0\rangle = e^{2\sum_r (L_0 + L_0^\dagger)} |0\rangle = \sum_{n=0}^\infty \frac{1}{n!} \left( \frac{2-r}{2} \right)^n (L_0 + L_0^\dagger)^n |0\rangle.
\]

(2.60)

\(^{12}\)Barton Zwiebach has suggested alternative derivation based on embedding the two-dimensional algebra \([L_0, L_0^\dagger] = L_0 + L_0^\dagger \) inside \( gl(2) \) and using its explicit representation in terms of two dimensional matrices.
Note that by (2.31) the states \( (L_0 + L_0^\dagger)^n |0\rangle \) are eigenstates of \( L_0 \) with eigenvalue \( n \). Although these states are far from being normal ordered, they are quite convenient. Almost normal ordered expression (normal ordered up to some \( L_0 \)’s hidden inside \( L_0^\dagger \)) can be written as

\[
( L_0 + L_0^\dagger)^n |0\rangle = \sum_{k=1}^n (-1)^{n-k} S_n^{(k)} (L_0^\dagger)^k |0\rangle,
\]

(2.61)

where \( S_n^{(k)} \) are the (signed) Stirling numbers of the first kind. They are defined in such a way that \((-1)^{n-k} S_n^{(k)}\) is the number of permutations of \( n \) symbols which have precisely \( k \) cycles. This expression might be useful for deriving various startling mathematical identities, but for our purposes it will be the form \( (L_0 + L_0^\dagger)^n |0\rangle \) which will prove to be most useful.

There is a second kind of \( L_0 \) eigenstates, which are perhaps more obvious, which are obtained simply by conformal transformation (2.8) of the \( L_0 \) eigenstates. As an example consider modes of the \( \tilde{c} \) ghost

\[
\tilde{c}(\tilde{z}) = \sum_{n=\infty}^\infty \frac{\tilde{c}_n}{\tilde{z}^{n-1}},
\]

given by

\[
\tilde{c}_n = \tan \circ c_n = \sum_{m=n}^\infty c_m \oint \frac{d\tilde{z}}{2\pi i} \tilde{z}^{n-2} \cos^2 \tilde{z} (\tan \tilde{z})^{-m+1},
\]

(2.63)

since \( \tilde{c}(\tilde{z}) = \tan \circ c(\tilde{z}) = \cos^2 \tilde{z} c(\tan \tilde{z}) \). Equivalently, using the more conventional passive viewpoint these modes can be expressed as

\[
\tilde{c}_n = \oint \frac{d\tilde{z}}{2\pi i} \tilde{z}^{n-2} \tilde{c}(\tilde{z}) = \sum_{m=n}^\infty c_m \oint \frac{d\tilde{z}}{2\pi i} \frac{1}{(1 + \tilde{z}^2)^2} (\arctan \tilde{z})^{n-2} \tilde{z}^{-m+1}.
\]

(2.64)

First few \( L_0 \) eigenstates are explicitly given by

\[
\begin{align*}
\tilde{c}_1 |0\rangle & = c_1 |0\rangle \\
\tilde{c}_0 |0\rangle & = c_0 |0\rangle \\
\tilde{c}_{-1} |0\rangle & = (c_{-1} - c_1) |0\rangle \\
\tilde{c}_{-2} |0\rangle & = \left( c_{-2} - \frac{2}{3} c_0 \right) |0\rangle \\
\tilde{c}_{-3} |0\rangle & = \left( c_{-3} - \frac{1}{3} c_{-1} + \frac{1}{3} c_1 \right) |0\rangle.
\end{align*}
\]

(2.65)

More complicated examples are given by products of several \( \tilde{\phi}_n \) modes of any number of primary fields. Just to give an example of a case where there are contractions between two mode operators
we use (2.38) to write a weight 5 $L_0$-eigenstate

$$L_{-3}L_{-2}|0\rangle = \left( L_{-3}L_{-2} + \frac{5}{3}L_{-3} \right) |0\rangle. \tag{2.66}$$

We have seen that there are basically two types of $L_0$ eigenstates. Ones which use a $n$-th power of $L_0 + L_0^\dagger$ (or a factor of $B_0 + B_0^\dagger$) and ones which use modes of primary operators $\bar{\phi}_n$. The former ones contain infinite sum of terms in the ordinary $L_0$ basis, whereas the second ones only finite number of them. Looking at (2.38) we see that we really should combine and use these two kinds of states together. One might be worried about overcounting if we include both kinds of states, but note that for instance the state $L_0^4|0\rangle$ with $L_0$ eigenvalue equal to one, is truly impossible to write as a linear combination of states like $\bar{\phi}_n|0\rangle$. In fact the only viable candidate $L_{-1}|0\rangle$ is identically equal to zero.

The star product rules for the above states of the $L_0$ basis can be readily worked out using (2.24). This leads to the following trivial but powerful lemma which belongs to the main results of the paper:

**Lemma:**

Let $\psi_1$ and $\psi_2$ be two eigenstates of $L_0$ with eigenvalues $h_1$ and $h_2$ respectively. Let us further assume that they are linear combinations of states of the form (2.24) with the only operator insertions allowed being $B_0^\dagger$, arbitrary power of $L_0^\dagger$ and any number of the $\bar{c}$ ghosts. Then the star product $\psi_1 * \psi_2$ is an infinite linear combination of $L_0$ eigenstates with eigenvalues $h \geq h_1 + h_2$.

**Proof:**

Let us write a basis of states with a definite $L_0$ eigenvalue $h$ in the form

$$\left( L_0 + L_0^\dagger \right)^n \bar{c}_{-p_1} \bar{c}_{-p_2} \cdots \bar{c}_{-p_k} |0\rangle, \tag{2.67}$$

$$\left( B_0 + B_0^\dagger \right) \left( L_0 + L_0^\dagger \right)^m \bar{c}_{-q_1} \bar{c}_{-q_2} \cdots \bar{c}_{-q_l} |0\rangle, \tag{2.68}$$

where $h = n + p_1 + \cdots + p_k = 1 + m + q_1 + \cdots + q_l$. The first basis element (2.67) can be rewritten up to a numerical factor as

$$\frac{d^{n+(p_1+1)+\cdots+(p_k+1)}}{dr^n d\ell_1^{(p_1+1)} \cdots d\ell_k^{(p_k+1)}} U_1^\dagger U_r \bar{c}(\tilde{x}_1) \cdots \bar{c}(\tilde{x}_k) |0\rangle \bigg| \begin{array}{c} r = 2 \\ \tilde{x}_i = 0 \end{array}. \tag{2.69}$$

Multiplying two states of this form using the formula (1.7) or (2.24)

$$U_1^\dagger U_r \bar{\phi}_1(\tilde{x})|0\rangle * U_s^\dagger U \bar{\phi}_2(\tilde{y})|0\rangle = U_{r+s-1}^\dagger \bar{\phi}_1 \left( \tilde{x} + \frac{\pi}{4}(s-1) \right) \bar{\phi}_2 \left( \tilde{y} - \frac{\pi}{4}(r-1) \right) |0\rangle, \tag{2.70}$$

we see that the total number of derivatives acting on the right hand side will be equal to the sum of the number of derivatives acting on the two factors on the left hand side. Some of the derivatives on the right hand side can act both on $U_1^\dagger U_r$ and the $\bar{c}$ ghosts, but regardless of
where they act they always increase the $\mathcal{L}_0$ eigenvalue by 1. Since setting $r = s = 2$ at the end leaves us with $U_3^\dagger U_3$ apart of powers of $\mathcal{L}_0 + \mathcal{L}_0^\dagger$ and modes of the $\tilde{c}$ ghosts, we have proven only $h \geq h_1 + h_2$ and not the equality.

For the states (2.68) we may use the identities (see Appendix D.1)

\[
\left( \left( B_0 + B_0^\dagger \right) \phi_1 \right) \ast \phi_2 = \left( B_0 + B_0^\dagger \right) \left( \phi_1 \ast \phi_2 \right) + (-1)^{\tilde{g}(\phi_1)} \frac{\pi}{2} \phi_1 \ast B_1 \phi_2,
\]

\[
\phi_1 \ast \left( \left( B_0 + B_0^\dagger \right) \phi_2 \right) = \left( -1 \right)^{\tilde{g}(\phi_1)} \left( B_0 + B_0^\dagger \right) \left( \phi_1 \ast \phi_2 \right) - \left( -1 \right)^{\tilde{g}(\phi_1)} \frac{\pi}{2} \left( B_1 \phi_1 \right) \ast \phi_2,
\]

\[
\left( \left( B_0 + B_0^\dagger \right) \phi_1 \right) \ast \left( \left( B_0 + B_0^\dagger \right) \phi_2 \right) = -\left( -1 \right)^{\tilde{g}(\phi_1)} \frac{\pi}{2} \left( B_0 + B_0^\dagger \right) B_1 \left( \phi_1 \ast \phi_2 \right) + \left( \frac{\pi}{2} \right)^2 \left( B_1 \phi_1 \right) \ast \left( B_1 \phi_2 \right),
\]

and thanks to the fact that $B_1$ and $\left( B_0 + B_0^\dagger \right)$ raise the $\mathcal{L}_0$ eigenvalue by one, we can reduce this case to the previous one.

Let us note that the lemma in its simplest form holds only for the assumed subsector of the string field theory, which fortunately is big enough for the goals of the present paper. As soon as one starts to introduce other operator insertions such as matter operators $\partial X$, $e^{ikX}$ etc., operator contractions seem to spoil the nice property that $h \geq h_1 + h_2$. It would be nice to find a way out, in order to be able to look efficiently for space-time dependent solutions. For the case of Wilson line marginal deformations generated by $i\partial X$ one possibility might be to replace in the above lemma the operator $\mathcal{L}_0$ with $\mathcal{L}_0 + N$, where $N$ is an $\alpha'$ counting operator. This could work, since each contraction of $i\partial X$’s is accompanied by an explicit factor of $\alpha'$.

### 3 Ghost number zero toy model

It has been suggested [34], that since $L_0$ has eigenvalue $-1$ on $c_1|0\rangle$, solving an equation $(L_0 - 1)|\Phi\rangle + |\Phi\rangle \ast |\Phi\rangle = 0$ for ghost number zero field $\Phi$ could teach us something about the true ghost number one solution. Indeed it was found that some of the coefficients of the tachyon solution in the matter sector of the ghost number one theory were strikingly close to the corresponding coefficients in the ghost number zero solutions. Although the precise relationship has never been discovered, and if it exists it is very likely not a simple one, we shall start with an analogous equation

\[
(\mathcal{L}_0 - 1) \Phi + \Phi \ast \Phi = 0,
\]

replacing $L_0$ with $\mathcal{L}_0$ and hoping to find some clues for the ghost number one case. Let us start with an ansatz in the form

\[
\Phi = \sum_{n=0}^{\infty} f_n |n\rangle,
\]

where we have introduced states

\[
|n\rangle = \frac{(-1)^n}{2^n n!} \left( \mathcal{L}_0 + \mathcal{L}_0^\dagger \right)^n |0\rangle.
\]
These states appear in the expansion of the wedge states

\[ |r\rangle = e^{\frac{2\pi i}{2}} \left( L_0 + L_0^\dagger \right) |0\rangle = \sum_{n=0}^\infty (r - 2)^n ||n\rangle \]  

(3.4)

and can be formally written as

\[ ||n\rangle = \oint \frac{dr}{2\pi i (r - 2)^n+1} |r\rangle. \]  

(3.5)

We do not pretend here to give meaning to wedge states \(|r\rangle\) with complex \(r\), we use the residue integral merely as a shorthand for taking derivatives and setting \(r = 2\). Thanks to the commutation relation \([L_0, L_0 + L_0^\dagger] = L_0 + L_0^\dagger\) the states \(||n\rangle\) are eigenstates of \(L_0\)

\[ L_0 ||n\rangle = n ||n\rangle, \]  

(3.6)

and using \(|r\rangle * |s\rangle = |r + s - 1\rangle\) one can derive easily their star products

\[ ||n\rangle * ||m\rangle = \sum_{k=n+m}^\infty \frac{k!}{n!m!(k - n - m)!} ||k\rangle. \]  

(3.7)

The fact that the star product of two states with \(L_0\) weights \(n\) and \(m\) contains weights only greater or equal to \(n + m\) is one of the key observations of the present paper that allowed much of the subsequent progress. Strictly speaking, as we have mentioned earlier, the statement is correct only in certain subsector of the string field theory. We will see in the next section that it is fortunately large enough for the physics of tachyon condensation.

Plugging our ansatz to the equation (3.1) we find a simple set of equations

\[ (n - 1)f_n = - \sum_{0 \leq p, q \leq n} \frac{n!}{p!q!(n - p - q)!} f_p f_q. \]  

(3.8)

First equation for \(n = 0\) is simply \(-f_0 = -f_0^2\) and requires us to set \(f_0 = 1\) or \(f_0 = 0\). In the first case the rest of the coefficients \(f_1, f_2, \ldots\) can be successively and uniquely determined and will be discussed in the next subsection. In the second case one has the freedom to set \(f_1\) to an arbitrary value. These solutions resemble one parameter pure gauge solutions and we shall comment on them in subsection 3.2.

3.1 ‘Tachyon’ solutions

Let us focus on the case \(f_0 = 1\) first. Calculating recursively first few coefficients from the equation (3.8) we find \(f_0 = 1, f_1 = -\frac{1}{2}, f_2 = \frac{1}{6}, f_3 = 0, f_4 = -\frac{1}{30}, \ldots\). Surprisingly these are nothing but the Bernoulli numbers, so that our solution becomes

\[ \Phi = \sum_{n=0}^\infty B_n ||n\rangle. \]  

(3.9)
The Bernoulli numbers $B_n$ are one of the most important number sequences in mathematics, with many properties, the most basic ones are for the readers convenience collected in appendix B

The equation (3.8) appears to be a novel identity for the Bernoulli numbers, somewhat similar to the Euler–Ramanujan identity. We present an elementary proof in the appendix B.

Having found the solution to (3.1) in the $|n\rangle\rangle$ basis we can express it in other forms as well. Using the generating function for the Bernoulli numbers (B.1), geometric series expansion, wedge state conservation laws and definition of the Riemann zeta function, we can write it in various forms

$$\Phi = \sum_{n=0}^{\infty} B_n |n\rangle\rangle = \frac{1}{2} \frac{1}{1 - e^{-\frac{1}{2}(L_0 + L_0^\dagger)}} |0\rangle$$

(3.10)

$$= \frac{1}{2} \sum_{n=0}^{\infty} (L_0 + L_0^\dagger) e^{-\frac{1}{2}(L_0 + L_0^\dagger)} |0\rangle = \frac{1}{2} \sum_{n=0}^{\infty} (L_0 + L_0^\dagger) |n + 2\rangle$$

(3.11)

$$= \sum_{n=0}^{\infty} \frac{1}{n + 2} L_0^\dagger |n + 2\rangle = \sum_{n=0}^{\infty} \frac{1}{2} L_0^\dagger \left( \frac{2}{n + 2} \right) L_0^\dagger + 1 |0\rangle$$

(3.12)

$$= L_0^\dagger 2^\frac{n}{2} \left( \zeta(L_0^\dagger + 1) - 1 \right) |0\rangle$$

(3.13)

demonstrating the richness (or perhaps redundancy) of our formalism. From (3.10) and (3.13) we can see that there is formally a term of the form $0/0$ or $0 \times \infty$ for $L_0 + L_0^\dagger$ or $L_0^\dagger = 0$. One has to be therefore a bit careful. In fact (3.11) and (3.12) cannot be correct, since the expressions are missing the $|0\rangle$ component. The step from (3.10) to (3.11) allows for writing the $L_0 + L_0^\dagger$ factor inside or outside the sum. If we write it outside the sum, we immediately find using (A.6, A.7) that it acts on

$$\sum_{n=0}^{\infty} |n + 2\rangle = \sum_{n=0}^{\infty} \left( |0\rangle - \frac{1}{3} L_2 |0\rangle + \frac{1}{30} L_4 |0\rangle + \frac{1}{18} L_2 L_2 |0\rangle + \cdots \right) +$$

$$+ \sum_{n=0}^{\infty} \frac{1}{(n + 2)^2} \left( \frac{4}{3} L_2 |0\rangle - \frac{4}{9} L_2 L_2 |0\rangle + \cdots \right) +$$

$$+ \sum_{n=0}^{\infty} \frac{1}{(n + 2)^4} \left( -\frac{8}{15} L_4 |0\rangle + \frac{8}{9} L_2 L_2 |0\rangle + \cdots \right) + \cdots .$$

(3.14)

All terms here are regular except the first term which is just the sliver state $|\infty\rangle$ found in multiplied by a divergent factor. Acting with $L_0 + L_0^\dagger$ on $(\sum_{n=0}^{\infty} 1) |\infty\rangle$ produces an ambiguous

As a side remark let us note that by expanding $\sum B_n |n\rangle\rangle$ in the powers of $L_0^\dagger$ Stirling numbers of the first kind appear naturally. Comparing this to the same expansion of $L_0^\dagger 2^\frac{n}{2} \left( \zeta(L_0^\dagger + 1) - 1 \right)$ we find rather curious relation between the Stieltjes constants $\gamma_n$ and products of Bernoulli and Stirling numbers. The sums which appear are only asymptotic series, but they can be summed to arbitrary precision using Padé approximants or exactly via Borel summation.

24
answer which has to be fixed to be the sliver state $|\infty\rangle$ itself with unit coefficient. First it has
to be in the kernel of $L_0 + L_0^\dagger$ and hence proportional to the sliver, second it has to contain
the vacuum $|0\rangle$ with unit coefficient. Adding the sliver to the (3.12) and trading the $L_0^\dagger$ for a
derivative with respect to the wedge angle, we can rewrite it in a simple form

$$
\Phi = |\infty\rangle - \sum_{n=2}^\infty \frac{d}{d\alpha} |n + \alpha\rangle \bigg|_{\alpha=0}.
$$

(3.15)

There is actually a much direct connection between the form $\Phi = \sum B_n |n\rangle$ and wedge state
representation (3.15) which will be useful in the ghost one case. It follows from (2.60) that

$$
\sum_{n=0}^\infty B_n |n\rangle = \sum_{n=0}^\infty \frac{B_n}{n!} \frac{d^n}{dr^n} U_r^\dagger |0\rangle\bigg|_{r=2} = |\infty\rangle - \sum_{n=0}^\infty \frac{B_n}{n!} \left( \frac{d^n}{dr^n} U_r^\dagger |0\rangle \bigg|_{r=\infty} - \frac{d^n}{dr^n} U_r^\dagger |0\rangle \bigg|_{r=2} \right)
$$

$$
= |\infty\rangle - \sum_{n=2}^\infty \frac{d}{dn} |n\rangle,
$$

(3.16)

where we used the fact that $U_r^\dagger |0\rangle = |\infty\rangle + O(1/r^2)$ and hence all the derivatives $\frac{d^n}{dr^n} U_r^\dagger |0\rangle$ vanish
at $r = \infty$, except for $n = 0$. In the last line we have used the Euler–Maclaurin sum formula

$$
\sum_{n=0}^\infty \frac{B_n}{n!} \left[ f^{(n)}(b) - f^{(n)}(a) \right] = \sum_{k=a}^{b-1} f'(k).
$$

(3.17)

In practise, the sum formula is most often used in a form (C.2) as a finite sum $n = 0, \ldots, N$
with a remainder $R_N$. As a series, it is usually rapidly divergent, although there are important
exceptions such as polynomials and exponentials. The Euler–Maclaurin series is often Borel
summable though, as was shown by Hardy [12]. In the ghost number one case we will demonstra-
for the tachyon coefficient, that the Borel summation indeed bridges the solution in the
$L_0$ basis written in terms of Bernoulli numbers and a corresponding sum over wedge states.

The form (3.15) is particularly useful for showing that it is indeed a solution of the equations
of motion. For the kinetic term we find

$$
(L_0 - 1)\Phi = -|\infty\rangle - \sum_{n=2}^\infty \frac{d}{d\alpha} \left( (n + \alpha - 2) \frac{d}{d\alpha} - 1 \right) |n + \alpha\rangle \bigg|_{\alpha=0}
$$

$$
= -|\infty\rangle - \sum_{n=2}^\infty (n - 2) \left( \frac{d}{d\alpha} \right)^2 |n + \alpha\rangle \bigg|_{\alpha=0},
$$

(3.18)

and similarly for the interaction term

$$
\Phi * \Phi = |\infty\rangle + \sum_{n,m=2}^\infty \frac{d}{d\alpha} \frac{d}{d\beta} |n + m + \alpha + \beta - 1\rangle \bigg|_{\alpha=\beta=0}
$$

$$
= |\infty\rangle + \sum_{k=3}^\infty (k - 2) \left( \frac{d}{d\alpha} \right)^2 |k + \alpha\rangle \bigg|_{\alpha=0},
$$

(3.19)
which completes our proof. To calculate the term \((\mathcal{L}_0 - 1)\Phi\) we had to use \(\mathcal{L}_0|\infty\rangle = 0\), which as we discuss in the appendix \(A\) is true only if we first regulate the sliver by replacing it with \(|r\rangle\) for large \(r\), act with \(\mathcal{L}_0\), do all the normal ordering and take the limit \(r \to \infty\) at the end. Without the regularization one would encounter divergent sums in the course of normal ordering.

It could seem therefore, that our solution is not that well behaved after all. Fortunately, this is not the case, as closer inspection of (3.15) reveals. In fact there is a large cancellation between the two terms in (3.15) at large levels. A simple way to see that is to replace the sum with the integral

\[
\Phi \sim |\infty\rangle - \int_2^\infty dn \frac{d}{d\alpha} |n + \alpha\rangle \bigg|_{\alpha = 0} = |0\rangle,
\]

(3.20)

which is quite good, albeit trivial approximation to the exact solution.

We can confirm the cancellation between the sliver and the sum parts by a more direct computation in the standard Virasoro basis of \(L_0\) eigenstates. For example the coefficient of \((L-2)^m|0\rangle\) for the sliver is \((-1)^m m! \sum_{n=2}^\infty \frac{d}{d\alpha} |n + \alpha\rangle \bigg|_{\alpha = 0}\), whereas for the sum part \(\sum_{n=2}^\infty \frac{d}{d\alpha} |n + \alpha\rangle \bigg|_{\alpha = 0}\) it is

\[
\frac{(-1)^m}{3^m m!} \sum_{n=2}^\infty \frac{d}{d\alpha} \left(1 - \frac{4}{(n + \alpha)^2}\right)^m \bigg|_{\alpha = 0}
\]

For finite \(m\) the sum can be expressed readily in terms of Riemann zeta function and one does not see much signs of cancellation. For \(m\) very large however, this infinite sum of Riemann zeta functions can be exactly evaluated up to small corrections

\[
\sum_{n=2}^\infty \frac{d}{d\alpha} \left(1 - \frac{4}{(n + \alpha)^2}\right)^m \bigg|_{\alpha = 0} = 1 + O \left(e^{-A m^{1/3}}\right), \quad A \gtrsim 1.21.
\]

(3.21)

The error can be rigorously bounded from above by the use of Euler–Maclaurin formula, the proof is relegated to the appendix \(C\). We thus see almost perfect cancellation between the two terms in (3.15). One could look for similar cancellations for other coefficients, we have done it also for \((L-4)^m|0\rangle\). This time we find the relevant sum to be

\[
\sum_{n=2}^\infty \frac{d}{d\alpha} \left(1 - \frac{16}{(n + \alpha)^4}\right)^m \bigg|_{\alpha = 0} = 1 + O \left(e^{-B m^{1/5}}\right), \quad B \gtrsim 0.80.
\]

(3.22)

In both cases there is thus a large cancellation between the sliver and the sum parts of the solution and that is the reason why the solution has good properties in level truncation.

Let us finish this section by giving an explicit expression for the coefficients in the standard Virasoro basis. From the form (3.15) it is easy to find

\[
\Phi = |0\rangle + \frac{8\zeta(3) - 9}{3} L_{-2}|0\rangle + \frac{64\zeta(5) + 65}{30} L_{-4}|0\rangle + \frac{64\zeta(5) - 16\zeta(3) - 47}{18} L_{-2} L_{-2}|0\rangle + \cdots
\]

\[
= |0\rangle + 0.2054 L_{-2}|0\rangle - 0.04544 L_{-4}|0\rangle + 0.007248 L_{-2} L_{-2}|0\rangle + \cdots.
\]

</table>

Table 1: Solution of the ghost number zero equations of motion in ordinary level truncation. The lowest level coefficients converge best to the exact answer. The convergence is slower than in the toy model [34], presumably because the level truncation truncates not only the field but also the kinetic term.

Just for comparison, the sliver is

$$|\infty\rangle = |0\rangle - \frac{1}{3} L_{-2}|0\rangle + \frac{1}{30} L_{-4}|0\rangle + \frac{1}{18} L_{-2}L_{-2}|0\rangle + \cdots$$

$$= |0\rangle - 0.33333 L_{-2}|0\rangle + 0.03333 L_{-4}|0\rangle + 0.005556 L_{-2}L_{-2}|0\rangle + \cdots .$$

(3.24)

Although not very obvious from the first four levels, one can easily go to much higher levels, to see clearly that the coefficients of $\Phi$ decay much faster than those of the sliver $|\infty\rangle$.

Finally let us compare our exact solution with a solution obtained by level truncation whose first few coefficients we give in Table 1. The convergence of the level truncation computation is rather slow, presumably due to the fact that in contrast to the equation $(L_0 - 1)\Phi + \Phi^* \Phi = 0,$ here the level truncation affects the equation itself by approximating $L_0.$

3.2 ‘Pure gauge’ solutions

As we mentioned earlier there is another class of solutions to (3.8) which starts as

$$f_0 = 0, \quad f_1 = \beta, \quad f_2 = -2\beta^2, \quad f_3 = 3\beta^2(2\beta - 1), \quad f_4 = -4\beta^2(6\beta^2 - 6\beta + 1), \ldots ,$$

(3.25)

where $\beta$ is an arbitrary parameter determining the solution. It looks quite impossible to guess the form of a general term, but the reader may check that it is given by

$$f_n = n! \oint \frac{dz}{2\pi i} \frac{\lambda z^{n+1}}{\lambda e^z - 1} = -n\lambda \text{Li}_{-n+1}(\lambda) - \delta_{n,1}\lambda,$$

(3.26)

where $\lambda = \frac{\beta}{\beta - 1}$ and Li$_n(z)$ is the polylogarithm function. The solution can be recast in a form similar to (3.15)

$$\Phi_\lambda = \frac{1}{2} \frac{(L_0 + L_0^\dagger)\lambda}{1 - \lambda e^{-\lambda/2(L_0 + L_0^\dagger)}}|0\rangle$$

(3.27)

$$= -\sum_{n=2}^{\infty} \lambda^{n-1} \frac{d}{d\alpha}|n + \alpha\rangle|_{\alpha=0},$$

(3.28)
and now it is a rather trivial task to show that (3.28) is a solution, just as we did for (3.15).

Note that since the coefficients of the wedge states are polynomials in $1/n^2$, the solution (3.28) is convergent for $|\lambda| \leq 1$ and hence makes most sense for $\beta \in (-\infty, 1/2)$. For $|\lambda| > 1$ one attempt could be to use (3.27) to expand around $\lambda = \infty$, but this would generate wedge states with $n = 1, 0, -1, -2, \ldots$. Although one might think that in some sense $|n\rangle = |-n\rangle$ as is true for the coefficients, the presence of $n = 0$ seems to invalidate the expansion. In fact it follows from the empirical study in [55], that wedge states $|n\rangle$ with $-1 < n < 1$ are not well behaved in level truncation. In spite of that, it seems that at least some of the values for $|\lambda| > 1$ could be meaningful.

For example for $\lambda = +\infty$, (i.e. $\beta = 1$) the series truncates after the first term and one finds $\Phi_{\lambda=\infty} = -\frac{1}{2} \left( \mathcal{L}_0 + \mathcal{L}_0^0 \right) |I\rangle = -\frac{1}{2} (K^L_t - K^R_t) |I\rangle$, where $|I\rangle = |1\rangle$ is the identity in the star algebra.\footnote{This state has been discussed previously in [63]. It was used to show that global symmetries generated by $K_n$ can be viewed as part of the gauge symmetry of string field theory.} Although this state does not look as ill behaved as wedge states $|n\rangle$ for $n \sim 0$, similar states have been shown to possess anomalous properties [64].

Finally, let us note that for the special value $\lambda = 1$, i.e. $\beta = \infty$ we find $\Phi_{\lambda=1} = -\sum_{n=2}^{\infty} \partial_n |n\rangle$ which looks just as (3.15) except for the sliver part. It reminds us of Yang-Mills theory, where the instantons can be viewed as singular limits of pure gauge configurations. In fact, one could regard our toy model 'tachyon solution' as a $\lambda \to 1$ limit of a pure gauge solution if one defines $\Phi_\lambda = \lim_{M \to \infty} \left[ \lambda^{M-1} |M\rangle - \sum_{n=2}^{M} \lambda^{n-1} \partial_n |n\rangle \right]$ and takes the limit $\lambda \to 1$ first.

4 Ghost number one – the real thing

Let us now face the real challenge, to solve the ghost-number-one equation of motion $Q_B \Psi + \Psi^* \Psi = 0$ of string field theory. As we have anticipated we will look for solutions in the $B_0 \Psi = 0$ gauge, where $B_0$ was introduced in (1.12). We shall start by constructing the true vacuum solution in the basis of $\mathcal{L}_0$ eigenstates discussed in section 2.5.

One of the methods used to solve string field equations of motion which worked in the Siegel gauge was to use a recursive approach [20]

$$\psi \to -\frac{b_0}{L_0} (\Psi^* \Psi) \quad (4.1)$$

starting with $\Psi^{(0)} \propto c_1 |0\rangle$.\footnote{There are some subtleties to this method, such as the need for adjusting the overall normalization at every step and also tricks to break some peculiar limit cycles. These issues do not affect the present discussion, the interested reader is referred to [20].} One could hope that the same strategy would work in our new gauge. Starting with $\Psi^{(0)} \propto \tilde{c}_1 |0\rangle$ and repeatedly star multiplying and acting with $B_0/\mathcal{L}_0$ (see
(1.15) leaves us in a simple invariant space which we can parameterize as

$$\Psi = \sum_{n,p} f_{n,p} \left( L_0 + L_0^\dagger \right)^n \bar{c}_p |0\rangle + \sum_{n,p,q} f_{n,p,q} \left( B_0 + B_0^\dagger \right) \left( L_0^\dagger + L_0 \right)^n \bar{c}_p \bar{c}_q |0\rangle,$$

(4.2)

where \( n = 0, 1, 2, \ldots \), and \( p, q = 1, 0, -1, -2, \ldots \). This will be thus our ansatz for finding the exact solution. Let us now plug the ansatz into the equations of motion \( Q_B \Psi + \Psi \ast \Psi = 0 \). For the coefficient of lowest level ghost number two state \( \tilde{c}_1 \tilde{c}_0 |0\rangle \) which appears in the equation of motion we find

$$f_{0,1} + \pi \left[ -\frac{1}{2} f_{0,1}^2 + f_{0,1} (f_{1,1} + 2f_{0,1,0}) \right] = 0.$$

(4.3)

Somewhat unexpectedly we see that imposing \( B_0 \) gauge sets \( f_{1,1} + 2f_{0,1,0} = 0 \) and therefore the equation can be solved easily, giving two solutions \( f_{0,1} = 0 \) or \( f_{0,1} = \frac{2}{\pi} \). As we discuss further in the appendix E, the first one corresponds to the pure gauge transformation of the vacuum.

Going further to the next level (i.e. the \( L_0 \) eigenvalue \( h = 0 \)) we have two states. For \( \tilde{c}_1 \tilde{c}_{-1} |0\rangle \) the equation can be trivially satisfied by the usual requirement of twist invariance which works in our gauge and basis as usually. For \( \left( L_0 + L_0^\dagger \right) \tilde{c}_1 \tilde{c}_0 |0\rangle \) we find

$$f_{1,1} + 2f_{0,1,0} + \pi \left[ \frac{1}{4} f_{0,1}^2 - \frac{3}{2} f_{0,1} f_{1,1} - f_{0,1} f_{0,1,0} + f_{1,1}^2 + 2f_{1,1} f_{0,1,0} + 2f_{0,1} (f_{2,1} + f_{1,1,0}) \right] = 0$$

(4.4)

Imposing the \( B_0 \) gauge the equation reduces to

$$\frac{1}{4} f_{0,1}^2 - f_{0,1} f_{1,1} = 0$$

(4.5)

which uniquely determines \( f_{1,1} = \frac{1}{4} f_{0,1} = \frac{1}{4 \pi} \). Had we chosen in the previous step \( f_{0,1} = 0 \), then \( f_{1,1} \) would be a free gauge parameter. It might be surprising that we find pure gauge solutions in our \( B_0 \) gauge, the reason is that the state \( \left[ \left( L_0 + L_0^\dagger \right) \tilde{c}_1 - \left( B_0 + B_0^\dagger \right) \tilde{c}_1 \tilde{c}_0 \right] |0\rangle \) is annihilated by all three operators \( B_0, Q_B \) and \( L_0 \). There are no other states like this, as one can easily check, since the kernel of \( L_0 \) at ghost number one is spanned by just three states. \(^\ddagger\)

\(^\ddagger\)Using the formulas in appendix D, one can show that for any states \( \psi_1, \psi_2 \) which satisfy \( B_0 \psi_1 = B_0 \psi_2 = 0 \) their star product obeys

$$B_0 (\psi_1 \ast \psi_2) = \frac{\pi}{4} \left( B_1^R \psi_1 \ast \psi_2 - (-1)^{g_0 (\psi_1)} \psi_1 \ast B_1^L \psi_2 \right).$$

(4.6)

Since both \( B_1^L \) and \( B_1^R \) increase \( L_0 \) eigenvalue by one, the coefficient in front of a state with \( L_0 = h \) in \( B_0 (\psi_1 \ast \psi_2) \) can receive contributions only from components of \( \psi_1 \) and \( \psi_2 \) with \( h_1 \)

\(^\ddagger\)This state is a bit reminiscent of the ghost dilaton \( (c_1 c_{-1} - \tilde{c}_1 \tilde{c}_{-1}) |0\rangle \) in closed string field theory which is also a \( Q_B \) exact state annihilated by \( b_0 \), but cannot be written as \( Q_B \Lambda \) with \( b_0 \Lambda = 0 \). It would be therefore interesting to study spectrum and interactions of string field theory around this solution.
and $h_2$ such that $h_1 + h_2 + 1 \leq h$, as we proved in section 2.5. Acting with $B_0$ on the equation of motion we have

$$\mathcal{L}_0 \Psi + B_0 (\Psi \ast \Psi) = 0. \quad (4.7)$$

This equation presents an infinite set of equations, one for each state in the Hilbert space at ghost number one. Let us truncate the equation (but not the string field) to the subset of states up to some maximal $h$. Then due to the above identity, and what we have showed above, this truncated system will depend on exactly the right number of coefficients of the string field. This is one of the main advantages of our choice of gauge and basis over traditional Siegel gauge and Virasoro basis.

Solving our equations to the first two $\mathcal{L}_0$ levels we find

$$\Psi = \frac{2}{\pi} \tilde{c}_1 |0\rangle + \frac{1}{2\pi} \left[ \left( \mathcal{L}_0 + \mathcal{L}^1_0 \right) \tilde{c}_1 |0\rangle - \left( B_0 + B^1_0 \right) \tilde{c}_0 |0\rangle \right] + \frac{1}{24\pi} \left[ \left( \mathcal{L}_0 + \mathcal{L}^1_0 \right)^2 \tilde{c}_1 |0\rangle - 2 \left( B_0 + B^1_0 \right) \left( \mathcal{L}_0 + \mathcal{L}^1_0 \right) \tilde{c}_1 \tilde{c}_0 |0\rangle \right] + \frac{\pi}{48} \tilde{c}_{-1} |0\rangle + \cdots. \quad (4.8)$$

Continuing further becomes rather tedious, so we have written Mathematica program to do it for us and going to higher levels we have discovered that all nonzero coefficients at level 12 have factor 691 in the numerator. This number is famous for being the prime numerator of the twelfth Bernoulli number, so it did not take long to guess the full form of the solution

$$\Psi = \sum_{n=0}^{\infty} \sum_{p=-1,1,3,5,...}^{\infty} \frac{\pi^p}{2n+2p+1} \cdot (-1)^n B_{n+p+1} \left( \mathcal{L}_0 + \mathcal{L}^1_0 \right)^n \tilde{c}_{-p} |0\rangle + \sum_{n=0}^{\infty} \sum_{p, q = -1}^{\infty} \frac{\pi^{p+q}}{2n+2(p+q)+3} \cdot (-1)^{n+q} B_{n+p+q+2} \left( B_0 + B^1_0 \right) \left( \mathcal{L}_0 + \mathcal{L}^1_0 \right)^n \tilde{c}_{-p} \tilde{c}_{-q} |0\rangle \quad (4.9)$$

which we have verified for the first 508 equations with 357 variables. Actually only 260 equations with 224 variables played role due to the twist symmetry. The details are presented in appendix E.

Direct proof that (4.9) is a solution of the equation of motion does not seem to be easy. In fact as we have checked the proof requires an infinite number of Euler-like identities like the one in (3.8) proved in appendix E. Much more convenient starting point for the proof is a form analogous to (3.15):

$$\Psi = \lim_{N \to \infty} \left[ \psi_N - \sum_{n=0}^{N} \partial_n \psi_n \right], \quad (4.10)$$

30
\[
\psi_n = \frac{2}{\pi^2} U_{n+2}^\dagger U_{n+2} \left[ \left( \mathcal{B}_0 + \mathcal{B}_0^0 \right) \tilde{c} \left( -\frac{n}{4} \right) \tilde{c} \left( \frac{n}{4} \right) + \frac{n}{2} \left( \tilde{c} \left( -\frac{n}{4} \right) + \tilde{c} \left( \frac{n}{4} \right) \right) \right] |0\rangle. \tag{4.11}
\]

One could derive that from (4.13) by similar manipulations as in (3.10), or by explicit Borel summation. The easiest way to show the equivalence however, is to realize that just as in the ghost number zero toy model, the expressions (4.9) and (4.10) are related via the Euler–Maclaurin series

\[
\sum_{n=0}^{\infty} \frac{B_n}{n!} \left[ f^{(n)}(b) - f^{(n)}(a) \right] = \sum_{k=a}^{b-1} f'(k) \tag{4.12}
\]

with \(a = 0, b = N + 1 \to \infty\) and \(f(k) = -\psi_k\). To see that one has to perform the derivatives with the help of formula (2.56). Before we move on to the somewhat involved proof of the equation of motion, we invite the reader to check that (4.10) is actually in the \(\text{B}_0\) gauge. To see that, one needs only the anticommutator \(\{\mathcal{B}_0, \tilde{c}(\tilde{z})\} = \tilde{z}\) and

\[
\mathcal{B}_0 U_{n+2}^\dagger U_{n+2} = U_{n+2}^\dagger U_{n+2} \left[ \mathcal{B}_0 - \frac{n}{2} \left( \mathcal{B}_0 + \mathcal{B}_0^0 \right) \right] \tag{4.13}
\]

which follows readily from the formulas in appendix D.1.

### 4.1 Proof of the equation of motion

We shall now give a proof that (4.10) is indeed a solution to the equation of motion \(Q_B \Psi + \Psi \ast \Psi = 0\). Let us start by ignoring the first term in (4.10) which, as one can readily verify by an explicit calculation, is effectively zero. By that we mean that all its contractions with Fock space states are zero. It can be also shown using (4.17) that it is irrelevant when star multiplied with itself or the other term in (4.10).

The action of \(Q_B\) on \(\Psi\) is quite simple

\[
Q_B \Psi = -\frac{2}{\pi^2} \sum_{n=0}^{\infty} \frac{d}{dn} \left\{ U_{n+2}^\dagger U_{n+2} \left[ \left( \mathcal{L}_0 + \mathcal{L}_0^0 \right) \tilde{c} \left( -\frac{n}{4} \right) \tilde{c} \left( \frac{n}{4} \right) + \frac{n}{2} \left( \tilde{c} \partial \tilde{c} \left( -\frac{n}{4} \right) + \tilde{c} \partial \tilde{c} \left( \frac{n}{4} \right) \right) \right] \right\} |0\rangle. \tag{4.14}
\]

To calculate the star product \(\Psi \ast \Psi\) it is convenient to rewrite (4.11) as

\[
\psi_n = \frac{2}{\pi} U_{n+2}^\dagger U_{n+2} \left[ B_1^L \tilde{c} \left( -\frac{n}{4} \right) \tilde{c} \left( \frac{n}{4} \right) + \tilde{c} \left( -\frac{n}{4} \right) \right] |0\rangle \tag{4.15}
\]

\[
\psi_n = \frac{2}{\pi} U_{n+2}^\dagger U_{n+2} \left[ -B_1^R \tilde{c} \left( -\frac{n}{4} \right) \tilde{c} \left( \frac{n}{4} \right) + \tilde{c} \left( +\frac{n}{4} \right) \right] |0\rangle \tag{4.16}
\]

\(^{17}\)Let us note equivalent but simpler form \(\psi_n = \frac{1}{2} c_1 |0\rangle \ast (B_1^L - B_1^R) |n\rangle \ast c_1 |0\rangle\), for \(n \geq 1\). Although it will not play a role in the subsequent analysis, it is worth mentioning that after taking the derivative with respect to \(n\) and summing over it, the ghost number zero solution appears naturally. This fact can possibly explain the quasi-pattern found in [34] discussed further in [20]. This new form might be also useful for bringing the solution to the partial isometry or pure-gauge like form advocated in [35].
Using the forms (4.15), (4.16) and the general rules of star multiplication from section 2 one finds

\[ \psi_n \ast \psi_m = \left( \frac{2}{\pi} \right)^2 U_{q+2}^\dagger U_{q+2} \left[ \frac{1}{\pi} \left( B_0 + B_0^\dagger \right) \cbar \left( \frac{\pi}{4} q \right) \cbar \left( -\frac{\pi}{4} q \right) - \frac{1}{2} \left( \cbar \left( \frac{\pi}{4} q \right) + \cbar \left( -\frac{\pi}{4} q \right) \right) \right] \]

\[ \times \left( \cbar \left( \frac{\pi}{4} (r + 1) \right) - \cbar \left( \frac{\pi}{4} (r - 1) \right) \right) |0\rangle, \quad (4.17) \]

where \( q = n + m + 1 \) and \( r = m - n \). It is important to note that the \( q \) and \( r \) dependent parts are factorized. Moreover, when we re-express the double sum over \( n \) and \( m \) as

\[ \sum_{n,m=0}^{\infty} = \sum_{q=1}^{\infty} \sum_{r=-q+1}^{q-1} \]

we see that summation of (4.17) over \( r \) becomes trivial and is given by the first and last terms. Before the summation we have to of course act with \( \partial_m \partial_n = \partial_q^2 - \partial_r^2 \), but that does not spoil this property. Using the identity \( (\partial^2 A) B - A \partial^2 B = \partial \left( A (\partial - \partial) B \right) \) we find

\[ \Psi \ast \Psi = \left( \frac{2}{\pi} \right)^2 \sum_{q=1}^{\infty} \frac{d}{dq} \left\{ U_{q+2}^\dagger U_{q+2} \left[ \frac{1}{\pi} \left( B_0 + B_0^\dagger \right) \cbar \left( \frac{\pi}{4} q \right) \cbar \left( -\frac{\pi}{4} q \right) - \frac{1}{2} \left( \cbar \left( \frac{\pi}{4} q \right) + \cbar \left( -\frac{\pi}{4} q \right) \right) \right] \right\} \]

\[ \times \left( \cbar_q - \cbar_q \right) \left( \cbar \left( \frac{\pi}{4} q \right) - \cbar \left( -\frac{\pi}{4} q \right) \right) \} |0\rangle. \quad (4.18) \]

After a little manipulation one can bring (4.18) to the form of (4.14) with a minus sign, and noting that the \( n = 0 \) term of (4.14) actually vanishes, the equation of motion \( Q_B \Psi + \Psi \ast \Psi = 0 \) is proven.

### 4.2 Proof of Sen’s first conjecture

Now we are going to prove Sen’s first conjecture using the explicit form of the solution (4.10). Sen’s first conjecture states [11, 12], that the energy density of the true vacuum found by solving the open string field theory equations of motion should be equal to minus the tension of the D25 brane i.e. \(-1/(2\pi^2 g_0^2)\). The energy density of a static configuration is minus the action\(^{18}\) so we are going to prove

\[ V(\Psi) = \frac{1}{g_0} \left[ \frac{1}{2} \langle \Psi, Q_B \Psi \rangle + \frac{1}{3} \langle \Psi, \Psi \ast \Psi \rangle \right] = -\frac{1}{2\pi^2 g_0^2}. \quad (4.19) \]

Since \( \Psi \) is a solution of the equations of motion, all we have to show is that

\[ \langle \Psi, Q_B \Psi \rangle = -\frac{3}{\pi^2}. \quad (4.20) \]

\(^{18}\text{Since we are interested in translationally invariant solutions, we normalize our correlators such that they do not depend on the volume of the space. In other words we are setting } V_{25} = 1 \text{ and we are not distinguishing between the energy and its density.}\)
Using the correlators from appendix D.2 we find

\[
\langle \psi_n, Q_B \psi_m \rangle = \frac{1}{\pi^2} \left( 1 + \cos \left( \frac{\pi r}{p} \right) \right) \left( -1 + \frac{p}{\pi} \sin \left( \frac{2\pi}{p} \right) \right) + 2 \sin^2 \left( \frac{\pi}{p} \right) \left[ -\frac{p-1}{\pi^2} + \frac{(p-2)^2 - r^2}{4\pi^2} \cos \left( \frac{\pi r}{p} \right) + \frac{pr}{2\pi^2} \sin \left( \frac{\pi r}{p} \right) \right],
\]

where we have introduced \( p = m + n + 2 \) and \( r = m - n \). We also find

\[
\langle \partial_n \psi_n, Q_B \partial_m \psi_m \rangle = -\frac{4(p-1)}{p^4} \cos \left( \frac{2\pi}{p} \right) + \frac{1}{8p^2} \left[ f_p(r+2) - f_p(r) + f_p(-r+2) - f_p(-r) \right],
\]

where we denote \( f_p(r) = -\left( (p-2)^2 - (r-2)^2 \right) (p^2 - r^2) \cos \left( \frac{\pi r}{p} \right) \).

Let us re-express the double sum as

\[
\sum_{n,m=0}^{\infty} = \sum_{p=2}^{\infty} \sum_{r=-p+2}^{p-2} \text{step 2},
\]

and observe that the special structure of (4.22) with the help of (4.23) gives readily

\[
\sum_{r=-p+2}^{p-2} \langle \partial_n \psi_n, Q_B \partial_m \psi_m \rangle = 0.
\]

This is of course welcome since it shows that the energy of pure gauge solutions \( \Psi_\lambda = -\sum_{n=0}^{\infty} \lambda^{n+1} \partial_n \psi_n \) is manifestly zero. But it also shows that if one carelessly interpreted (4.10) as \( -\sum_{n=0}^{\infty} \partial_n \psi_n \) one would find zero energy, at least with the above order of summation. In fact one could find arbitrary result since the double sum \( \sum_{n,m=0}^{\infty} \langle \partial_n \psi_n, Q_B \partial_m \psi_m \rangle \) is not absolutely convergent.

In our case, however, the sum is properly regularized (4.11) and there is thus no ambiguity left. We would like to stress that the regularization (4.11) is in no way ad-hoc, but was imposed on us by the use of the Euler–Maclaurin formula and confirmed by the analogy with ghost number zero toy model. In the next two subsections we shall provide two other rather orthogonal numerical verifications, which give the same energy with high precision.

With our regularization we thus have

\[
\langle \Psi, Q_B \Psi \rangle = \lim_{N \to \infty} \left[ \langle \psi_N, Q_B \psi_N \rangle - 2 \sum_{m=0}^{N} \langle \psi_N, Q_B \partial_m \psi_m \rangle + \sum_{n=0}^{N} \sum_{m=0}^{N} \langle \partial_n \psi_n, Q_B \partial_m \psi_m \rangle \right].
\]

For the first term one readily finds from (4.21)

\[
\lim_{N \to \infty} \langle \psi_N, Q_B \psi_N \rangle = \frac{1}{2} + \frac{2}{\pi^2}.
\]
For the third term we rewrite the sum over the square \((n, m) \in [0, N] \times [0, N]\) as a sum over the lower left and upper right triangles, i.e.

\[
\sum_{n=0}^{N} \sum_{m=0}^{N} = \sum_{n=p=2}^{N+2} \sum_{r=-p+2}^{p-2} + \sum_{p=N+3}^{2N+2} \sum_{r=-2N+p-2}^{N-p+2}.
\]

The first double sum does not contribute by (4.24), the second one gives

\[
\sum_{n=p=2}^{N+2} \sum_{r=-p+2}^{p-2} \langle \partial_n \psi_n, Q_B \partial_m \psi_m \rangle = \sum_{j=1}^{N} \frac{4}{(2+j+N)^4} \left[ (j^2 - (N+1)^2) \cos \left( \frac{2\pi}{2+j+N} \right) + \right.
\]
\[
\left. (j^2 - 1)(N+1)^2 \cos \left( \frac{\pi}{2+j+N} \right) + j^2 N(N+2) \cos \left( \frac{2\pi j}{2+j+N} \right) \right].
\]

Note that for every fixed \(j\) the summand on the right hand side goes as \(16\pi^2(j^3 - j)/N^4\) for large \(N\). The dominant contribution comes therefore from large \(j\)’s. Let us introduce \(x = j/N\) and expand the summand in \(1/N\) keeping \(x \in (0, 1]\) fixed

\[
\frac{8\pi x^2}{(1+x)^5} \sin \left( \frac{\pi}{2+x} \right) \frac{1}{N} + O \left( \frac{1}{N^2} \right).
\]

Since the sum involves \(N\) bounded terms we can safely ignore the \(O(1/N^2)\) part and the sum of the first term is in the limit nothing but the Riemann definition of an integral. Therefore

\[
\lim_{N \to \infty} \left[ \sum_{n=0}^{N} \sum_{m=0}^{N} \langle \partial_n \psi_n, Q_B \partial_m \psi_m \rangle \right] = \int_0^1 dx \frac{8\pi x^2}{(1+x)^5} \sin \left( \frac{\pi}{2+x} \right) = \frac{1}{2} - \frac{1}{\pi^2}.
\]

Similarly for the middle term in (4.25) we find using (4.21) and \(\partial_m = \partial_p + \partial_r\) expression where we set \(p = N(1+x) + 2, r = (x-1)N\). Expanding in \(N\) keeping \(x = m/N\) fixed we find again Riemann integral

\[
\lim_{N \to \infty} \left[ \sum_{m=0}^{N} \langle \psi_N, Q_B \partial_m \psi_m \rangle \right] = \int_0^1 dx \frac{4\pi x}{(1+x)^3} \sin \left( \frac{\pi}{1+x} \right) = \frac{1}{2} + \frac{2}{\pi^2}.
\]

 Altogether

\[
\langle \Psi, Q_B \Psi \rangle = \frac{1}{2} + \frac{2}{\pi^2} - 2 \left( \frac{1}{2} + \frac{2}{\pi^2} \right) + \frac{1}{2} - \frac{1}{\pi^2} = -\frac{3}{\pi^2},
\]

which completes our proof of Sen’s first conjecture.
4.3 Transforming to the Virasoro basis

In this section we would like to demonstrate that our solution (4.10, 4.11) is a well behaved element of string field theory Hilbert space, just like the Siegel gauge solution found by Sen and Zwiebach in their seminal paper [5]. We shall not delve here into the issue of regularity in string field theory, instead we shall give first few coefficients of the solution in the standard Virasoro basis, which is the one used in level truncation.

As we have already mentioned, the first term in (4.10) does not contribute in level truncation, and thus with a little manipulation we arrive to a convenient, almost normal ordered form

\[ \Psi = -\frac{1}{\pi} \sum_{n=2}^{\infty} \frac{d}{dn} \left\{ \frac{n}{\pi} B_0^\dagger \left[ -\frac{n}{2} \left( -\frac{n}{2} \right) \right] + \tilde{c} \left( -\frac{2n}{2} \right) + \tilde{c} \left( \frac{n}{2} \right) \right\} \].

(4.32)

Using the explicit form of the canonically ordered wedge state (2.20), see also appendix A, and the definitions of \( B_0^\dagger \) and \( \tilde{c} \) we easily derive all the coefficients at low levels. Just for illustration let us write the exact solution up to level 4 following the notation of Sen and Zwiebach:

\[ \Psi = tc_1|0\rangle + uc_{-1}|0\rangle + vL_{-2}c_1|0\rangle + wb_{-2}c_0c_1|0\rangle + +AL_{-4}c_1|0\rangle + BL_{-2}c_1|0\rangle + Cc_{-3}|0\rangle + Db_{-3}c_{-1}|0\rangle + +Eb_{-2}c_{-2}c_1|0\rangle + FL_{-2}c_{-1}|0\rangle + +w_1L_{-3}c_0|0\rangle + w_2b_{-2}c_{-1}c_0|0\rangle + w_3b_{-4}c_0c_1|0\rangle + w_4L_{-2}b_{-2}c_0c_1|0\rangle \] (4.33)

For the first four coefficients (level 0 and level 2) we find

\[ t = \sum_{n=2}^{\infty} \frac{d}{dn} \left[ \frac{n}{\pi} \sin^2 \left( \frac{\pi}{n} \right) \left( -1 + \frac{n}{2\pi} \sin \left( \frac{2\pi}{n} \right) \right) \right] \]
\[ u = \sum_{n=2}^{\infty} \frac{d}{dn} \left[ \left( \frac{4}{n\pi} - \frac{2}{\pi} \sin^2 \left( \frac{\pi}{n} \right) \right) \left( -1 + \frac{n}{2\pi} \sin \left( \frac{2\pi}{n} \right) \right) \right] \]
\[ v = \sum_{n=2}^{\infty} \frac{d}{dn} \left[ \left( \frac{4}{3n\pi} - \frac{n}{3\pi} \sin^2 \left( \frac{\pi}{n} \right) \right) \left( -1 + \frac{n}{2\pi} \sin \left( \frac{2\pi}{n} \right) \right) \right] \]
\[ w = \sum_{n=2}^{\infty} \frac{d}{dn} \left[ \sin^2 \left( \frac{\pi}{n} \right) \left( \frac{8}{3n\pi} - \frac{2n}{3\pi} + \frac{n^2}{3\pi^2} \sin \left( \frac{2\pi}{n} \right) \right) \right]. \] (4.34)

These sums do not appear to have simple analytic expressions, although they can be rewritten in an interesting way using the Bernoulli numbers. We can simply expand the trigonometric functions into their Taylor series and exchange the two infinite sums to find fast converging sums.
such as
\[
  t = \sum_{k=2}^{\infty} (-1)^k (2\pi)^{2k-1} \left( \frac{(2k-1)(2^{2k} - 2 - 2k)}{(2k+1)!} \right) \zeta(2k) = \tag{4.35}
\]
\[
= \sum_{k=2}^{\infty} (2\pi)^{4k-1} \frac{(2k-1)(k+1 - 2^{2k-1})}{(2k)!(2k+1)!} B_{2k}. \tag{4.36}
\]

For practical purposes one can keep the sums (4.34) as they are, since all summands behave as $1/n^4$ for large $n$, and can be easily evaluated numerically with arbitrary precision.\(^{19}\)

We have computed the exact coefficients with nine digit precision up to level 10, some numerical results are given in appendix F.\(^{20}\) Let us present here the complete list of the exact coefficients up to level 4:

\[
\begin{array}{cccc}
  t & = & 0.55346558 & A = -0.030277583 \\
u & = & 0.45661043 & B = 0.0045805832 \\
v & = & 0.13764616 & C = -0.16494614 \\
w & = & -0.14421001 & D = 0.16039444 \\
\end{array}
\]

One thing one can do with these coefficients is to check whether the solution obeys the expected symmetries. From the explicit form (4.10, 4.11) or (4.32) one sees that $K_{\text{matter}}^1 \Psi = 0$, since $K_{\text{matter}}^1$ commutes with all the terms, including the common factor $U_n^\dagger U_n$. It is a general rule, that if a solution of $Q_B \Psi + \Psi^* \Psi = 0$ is annihilated by a star algebra derivative $D$, it must be annihilated also by $[Q_B, D]_{\pm}$. For the case at hand, it is easy to check

\[
\begin{align*}
  5A + 3B + v & = 0 \quad \text{(4.37)} \\
  w_1 & = 0 \quad \text{(4.38)} \\
  20A + 12B + 4D - 4F - 8w_1 & = 0 \quad \text{(4.39)} \\
  15A + 9B + v + w - 10w_1 + 5w_3 + 3w_4 & = 0 \quad \text{(4.40)}
\end{align*}
\]

as dictated by $K_{\text{matter}}^1 \Psi = [K_{\text{matter}}^1, Q_B] \Psi = 0$. Actually one can see those identities to be true also from the explicit expressions (4.34) before the sums are carried out.

In Siegel gauge there is somewhat unexpected $SU(1,1)$ symmetry\(^{36}\)\(^{31}\)\(^{32}\)\(^{20}\), which implies $(c\partial c)_0 \Psi = 0$. Note that $(c\partial c)_0$ is a star algebra derivative, whose commutator with $Q_B$ is zero. This invariance enforces the Siegel gauge $b_0 \Psi = 0$. In addition it implies a constraint $C + 3D = 0$ and even more constraints at higher levels. It is definitely of some interest to see whether our $B_0$ gauge solution possesses similar symmetries. Given the fact that we have

\(^{19}\)To speed up the convergence it is convenient to sum first explicitly given number of terms (e.g. first one hundred), expand the remaining terms in powers of $1/n$ keeping only first few orders and sum them exactly using the Riemann zeta function. Note that in the $1/n$ expansion only terms $1/n^4, 1/n^6, 1/n^8 \ldots$ appear.

\(^{20}\)To be completely honest, at level 10 due to inefficiency of our computer program, we left our solution expressed in terms of $L^\text{tot}_n$ and the ghosts, instead of $L^\text{matter}_n$ and the ghosts. This does not affect the check on the D-brane energy as given below, which we were primarily interested in.
expressions like (4.34) we can look for such symmetries systematically. Surprisingly we have found one more independent identity
\begin{equation}
2A + 4D - 3E + 2F - 3w_2 + 3w_4 = 0.
\end{equation}
We were not able to find any simple origin, it might be just an accidental symmetry. Apart of \( K_1^{\text{matter}} \Psi = [K_1^{\text{matter}}, Q_B] \Psi = 0 \) there is one more obvious symmetry \( K_1 B_1 B_0 \Psi = 0 \) which gives some exact constraints manifest in level truncation, but they become nontrivial only at level 6. To complete the discussion of symmetries we remind the reader at this point of the obvious twist symmetry
\begin{equation}
(-1)^{L_0-1} \Psi = \Psi,
\end{equation}
which we in fact imposed when solving the equations of motion in the \( L_0 \) basis, and which our solution shares with the Siegel gauge solution. Finally, there is yet another symmetry, which as far as we can see, is obvious only from the solution (4.34) in the \( L_0 \) basis. All the terms with \( L_0 \) eigenvalue equal to \( m \), are multiplied by the Bernoulli number \( B_{m+1} \). Now, all odd index Bernoulli numbers vanish except \( B_1 \) and it turns out that the term multiplied by \( B_1 \) is annihilated by all three operators \( Q_B, B_0 \) and \( L_0 \). We can thus write the symmetry as
\begin{equation}
(-1)^{L_0-1} L_0 \Psi = L_0 \Psi.
\end{equation}
It would be interesting to see if it can be translated to the Virasoro basis.

One slight disadvantage of the \( B_0 \) gauge is that the gauge fixing condition is broken by level truncation. As we noted earlier, by virtue of (4.13) the solution indeed obeys \( B_0 \Psi = 0 \) exactly, but after truncating it to level 4 the gauge conditions become
\begin{align}
w_i &= 0, \quad i = 1, 2, 3, 4 \\
\frac{2}{3} E + w &= 0,
\end{align}
out of which only \( w_1 = 0 \) is true exactly. The last condition is true within 83\% and for \( w_{2,3,4} \) we can only say that they are two to three times smaller than similar coefficients without \( c_0 \). We hope that this level dependent gauge fixing would not pose problems and that the numerical high level computations of Moeller and Taylor [19] and Gaiotto and Rastelli [20] would converge to our solution. On the other hand, we do not expect convergence properties superior to the Siegel gauge, because of our experience with the ghost number zero equation discussed in section 3.

Finally we would like to demonstrate that our solution yields the correct D25-brane energy density also in level truncation. Note that this is the main problem with the identity based solutions [38]. To check the energy we have evaluated the kinetic term \( \langle \Psi, Q_B \Psi \rangle \) up to level 10. The values are summarized in the following table
\[
\begin{array}{cccccc}
L = 0 & L = 2 & L = 4 & L = 6 & L = 8 & L = 10 \\
-1.007766 & -1.007815 & -1.004499 & -1.003217 & -1.002556 & -1.002130
\end{array}
\]

Table 2: Energy density normalized by the D-brane tension at various levels of truncation of the exact solution. The numbers which appear are \( \langle \Psi, Q_B \Psi \rangle \) divided by \( 3/\pi^2 \).

### 4.4 Padé approximants and Borel summation

Instead of passing through the representation in terms of wedge states or using level truncation one could attempt to compute the energy density or coefficients in the Virasoro basis directly from the tachyon solution written in terms of Bernoulli numbers. As we shall see both tasks lead to divergent series, but ones which can be handled with. Let us start by ‘regularizing’ our solution by replacing \( \Psi \) with \( z^{L_0} \Psi \). In the \( \mathcal{L}_0 \) level expansion different levels will acquire different integer powers of \( z \). The ‘regularization’ is then removed in the limit \( z \to 1 \). We have put regularization in quotation marks, since as we shall see \( z \) does not quite regularize the energy nor the Virasoro coefficients but merely provides an expansion parameter for an asymptotic series.

#### Energy

Let us start with the computation of the energy as a formal expansion in \( z \). Using the explicit solution and few correlators from appendix D.2 we arrive to

\[
\langle \Psi, z^{L_0} Q_B z^{L_0} \Psi \rangle = -\frac{4}{\pi^2 z^2} + \left( \frac{1}{12} + \frac{1}{3\pi^2} \right) - \left( \frac{1}{90} + \frac{\pi^2}{1920} \right) z^2 + \left( \frac{17}{5040} - \frac{11\pi^2}{17920} - \frac{\pi^4}{193536} \right) z^4 + \left( -\frac{113}{60480} + \frac{2413\pi^2}{1935360} - \frac{137\pi^4}{580680} - \frac{\pi^6}{22118400} \right) z^6 + \cdots .
\]

(4.46)

Trying to evaluate the series numerically for \( z = 1 \) one immediately finds that the series is divergent. The most common method for dealing numerically with divergent series is the Padé approximation. This, a bit mysterious, but often very successful method approximates a series outside its radius of convergence by a rational function. Given a formal power series \( f(z) \sim \sum a_n z^n \), Padé approximant \( P_{N,M}^N(z) \) is a ratio of two polynomials of degree \( N \) and \( M \), such that its power series matches the one of \( f(z) \) up to \( z^{N+M} \). In table 3 we give a Padé approximation \( P_{n+2}^n \) for even \( n = 0, \ldots, 18 \) and compare it with the naive evaluation which can be viewed as \( P_{2n}^n \). Note that both \( P_{n+2}^n \) and \( P_{2n}^n \) match (4.46) to the same order.

The first column with \( P_{2n}^n \) is also nothing but the definition of the energy in the \( \mathcal{L}_0 \)-level truncation. Interestingly we see that with level 2 we get very close to the exact value and up \[21\]The closed form expression we found for the series contains six fold sum of a product of two Bernoulli numbers, six factorials (five of them in the denominator) and some powers of 2 and \( \pi \). We didn’t dare to simplify it, however we noticed that at given order of \( z^n \) the term with the highest power of \( \pi \) simplifies to \( -\frac{1}{2(n+2)!} |B_{n+2}| \left( \frac{\pi}{2} \right)^n \) for \( n \geq 1 \). There is an easy proof which uses the Euler identity (B.3).
to level 6 we are still within few percent. At higher levels the divergent character of the series starts to show up.\footnote{This raises the unwelcome possibility that ordinary $L_0$-level truncation in Siegel gauge would show up a similar behavior, perhaps at some higher level $\geq 20$. The overshooting of the correct energy at level 14 found by Gaiotto and Rastelli \cite{Gaiotto:2003aw} could be attributed to it. It is not clear to us whether the high level extrapolations of \cite{Gaiotto:2003bb,Gaiotto:2003aw} resolve the issue.}

Given the relative ease of evaluating (4.46) we carried out the expansion up to $z^{50}$ and to our surprise we found that to this order the Padé approximations do not improve much beyond the $10^{-6}$ accuracy. Looking separately at the contribution of the first term in (4.9) only, we found that the convergence is rather irregular with a rough pattern of plateaux of constant accuracy and occasional bigger jumps towards better accuracy. It seems that to reach accuracy of $10^{-9}$ one would need at least a Padé approximant $P_{50}^{50}$. The somewhat irregular convergence is in sharp contrast with the behavior of other series such as the celebrated Euler series $\sum (-1)^n n! z^n$ or $\sum B_n z^n$, (for which we know the exact answer by Borel summation), and where we checked that the Padé approximants converge to the exact answer monotonically.

\textit{Tachyon coefficient}

Let us now see how one can get the tachyon coefficient $t$ directly from (4.9). As in the case of the energy we ‘regularize’ our solution by considering $z^{L_0} \Psi$ and the tachyon coefficient will become $z$ dependent. Let us write $t = t_1 + t_2$ for the two contributions coming from the two

\begin{table}
\begin{tabular}{|c|c|c|}
\hline
$n$ & $P_{2n}^2$ & $P_{n+2}^n$ \\
\hline
$n = 0$ & -1.3333 & -1.33333333 \\
$n = 2$ & -1.0015 & -0.99501646 \\
$n = 4$ & -0.98539 & -1.00100097 \\
$n = 6$ & -1.0327 & -1.00032831 \\
$n = 8$ & -1.3054 & -1.00100097 \\
$n = 10$ & 6.7582 & -1.00003423 \\
$n = 12$ & 256.34 & -0.99999846 \\
$n = 14$ & -21575 & -0.99999945 \\
$n = 16$ & -3.6391 \times 10^6 & -0.999999819 \\
$n = 18$ & 6.5671 \times 10^7 & -1.00000064 \\
\hline
\end{tabular}
\end{table}

Table 3: The Padé approximation for the normalized energy $\frac{\pi^2}{3} \langle \Psi, z^{L_0} Q_B z^{L_0} \Psi \rangle$ evaluated at $z = 1$. The first column is in fact a trivial approximation, a naively summed series with behavior typical for asymptotic series. The second column nicely confirms Sen’s first conjecture despite somewhat irregular convergence at higher orders.
terms in (4.9). Using (D.14) from appendix D.2 one finds

\[
t_1(z) = \sum_{n=0}^{\infty} \sum_{p=-1 \atop p \text{ odd}}^{\infty} z^{n+p} \frac{(-1)^n}{n!} \left( \frac{\pi}{2} \right)^p \frac{B_{n+p+1}}{2^{n+p+1}} (p-1)_n \left[ \frac{2^p}{(p+1)!} \left( -1 \right)^{\frac{p+1}{2}} + \frac{1}{2} \delta_{p,-1} \right], \quad (4.47)
\]

\[
t_2(z) = \sum_{n=0}^{\infty} \sum_{p=-1 \atop p \text{ odd}}^{\infty} \sum_{q=0 \atop q \text{ even}}^{\infty} z^{n+p+q+1} \frac{(-1)^{n+q}}{n!} \left( \frac{\pi}{2} \right)^{p+q} \frac{B_{n+p+q+2}}{2^{n+p+q+2}} (p+q)_n \times \left[ \frac{2^p}{(p+1)!} \left( -1 \right)^{\frac{p+1}{2}} + \frac{1}{2} \delta_{p,-1} \right] \left[ \frac{2^q}{(q+1)!} \left( -1 \right)^{\frac{q+2}{2}} - \delta_{q,0} \right], \quad (4.48)
\]

which as one can easily check are again divergent series due to the presence of Bernoulli numbers and the Pochhammer symbol \((x)_n = x(x+1)\ldots(x+n-1)\). Before attempting the Borel summation which may not always work and often requires some labor we propose as a rule of thumb to check the series first with Padé approximants.\(^{23}\) We have found that the Padé approximants \(P_N^t\) to \(t_{1,2}(z)\) evaluated at \(z = 1\) approach the expected values

\[
t_1 = \frac{\pi}{2} + \sum_{k=1}^{\infty} (-1)^k \left( \frac{2\pi}{2k+1} \right)^{2k+1} \frac{k}{(2k+2)!} \zeta(2k+1) = 0.277658977\ldots \quad (4.49)
\]

\[
t_2 = -t_1 + \sum_{k=1}^{\infty} (-1)^k \left( \frac{2\pi}{2k-1} \right)^{2k-1} \frac{(2k-1)}{(2k+1)!} \left( \frac{2^{2k}-2k-2}{2^{2k}} \right) \zeta(2k) = 0.275806609\ldots \quad (4.50)
\]

in a similar manner as the energy, or perhaps a bit faster. Originally we found these exact expressions by performing the Borel summation, but they can be most easily derived from (4.10) and (4.11). Note that the first term in (4.10) contributes \(\pi/2\) in (4.49) and \(-\pi/2\) in (4.50) inside \(t_1\). Although it is not true in general that the Padé approximation to a sum of functions is a sum of their Padé approximations, we see that the sum of Padé approximants to \(t_1\) and \(t_2\) at \(z = 1\) approaches the correct value \(t = 0.553465587\ldots\). One could perform the Padé approximation directly for the sum \(t_1 + t_2\) with the same results, although for finite \(N\) the results differ.

Let us now sketch how one can perform Borel summation for the series (4.47)-(4.48). This was actually our first computation of \(t\) before we discovered the simple representation in terms of wedge states. First observe that both expressions (4.47)-(4.48) contain a common part which can be summed separately for \(r \geq 2\) and \(\text{Re } z > 0\)

\[
\sum_{n=0}^{\infty} (r-2)_n \frac{B_{n+r}}{n!} \left( \frac{z}{2} \right)^{n+r-1} = (-1)^r \left[ \frac{(r-1)(r-2)}{z} + \frac{r-2}{2} + \frac{z}{12} \sum_{j=0}^{r-3} \frac{2^j}{(2j)!} \right] j+2 (r-1)! \psi_{j+1} \left( \frac{z}{2} \right) \left( j+3 \right)! (r-j-3)! \right].
\]

\[\quad (4.51)\]

\(^{23}\)There is actually a theorem that under certain conditions both Borel summation and Padé approximation lead to the same result. I thank J. Fischer for a discussion on this issue.
In this formula $\psi_n(z) = (-1)^{n+1} n! \sum_{k=0}^{\infty} (z+k)^{-n-1}$ denotes the polygamma function. For lower values $r = 0$ and $r = 1$ the sum on the left hand side terminates and one finds $2z^{-1} + 1 + z/12$ and $-(z+6)/12$ respectively. Using this result one can readily derive

$$t_1(z) = \frac{\pi}{2z} + \sum_{k=1}^{\infty} (-1)^k \left( \frac{2\pi}{z} \right)^{2k+1} \frac{k}{(2k+2)!} \zeta \left( 2k+1, \frac{2}{z} \right)$$

$$t_2(z) = -t_1(z) + \frac{1}{z} \sum_{k=1}^{\infty} (-1)^k \left( \frac{2\pi}{z} \right)^{2k-1} \frac{(2k-1) \left( \frac{2^{2k} - 2k - 2}{(2k+1)!} \right) \zeta \left( 2k, \frac{2}{z} \right)}{(2k-1)!}$$

where $\zeta(n,z) = \sum_{k=0}^{\infty} (k+z)^{-n}$ is the Hurwitz zeta function. For the sum $t(z) = t_1(z) + t_2(z)$ we find finally

$$t(z) = \frac{1}{z} \sum_{k=1}^{\infty} (-1)^k \left( \frac{2\pi}{z} \right)^{2k-1} \frac{(2k-1) \left( \frac{2^{2k} - 2k - 2}{(2k+1)!} \right) \zeta \left( 2k, \frac{2}{z} \right)}{(2k-1)!}$$

Let us make few comments. The easiest way to obtain (4.55) is by using the wedge state representation (4.10, 4.11). Note that the action of $z L_0$ effectively replaces all factors of $n$ with $nz$. From (4.54) for $z = 1$ follows immediately (4.35), one has to use the identity $\zeta(n, 2) = \zeta(n) - 1$ and observe that the term $-1$ does not contribute. Finally observe that the function $t(z)$ is holomorphic at $z = \infty$ (the functions $t_1(z)$ and $t_2(z)$ have first order poles there which cancel each other). On the contrary it has an essential singularity at $z = 0$ as can be seen from (4.55), since $z = 0$ is a cumulation point of essential singularities at $z = -2/n$. This explains why the series (4.47) and (4.48) have zero radius of convergence.

5 Conclusions and outlook

We have found the first exact and fully explicit nonsingular solution describing the non-perturbative tachyon vacuum in Witten's cubic open bosonic string field theory. We also definitely proved Sen's first conjecture, which relates the value of the tachyon potential at the minimum to the D-brane tension known from the annulus computation. Good evidence was presented that our solution is quite regular from the point of view of level truncation. It would be interesting to confirm it by direct numerical computations.

We have presented our solution in two different forms. In the first form, the solution is written in the basis of $L_0$ eigenstates, and is given in terms of Bernoulli numbers. In this basis it was rather straightforward to find the solution, although it was not easy to prove that it actually is a solution. Another advantage of this basis is that it is rather easy to study exactly a large
sector of the full infinite-dimensional gauge symmetry and thus clearly discriminate the tachyon solution from pure gauge solutions.

The second form can be most elegantly obtained from the first one by noticing that it is an Euler–Maclaurin series of certain sum over wedge states with ghost insertions. For this form of the solution it was fairly easy to prove that it solves the equations of motion, and that it obeys Sen’s first conjecture.

Clearly now we are at a stage where many new exciting things can be done. There are still two other Sen’s conjectures that remain to be proved. We believe that with the tools developed in this paper the cohomology of the kinetic operator at the vacuum can be studied rather easily, and hopefully shown to be empty. To study space-time-dependent solutions, such as higher codimension D-branes or rolling tachyon backgrounds could also be possible with the presented methods, although the presence of nontrivial contractions among matter operators makes their study a challenge. We hope that one could also study the question of how closed strings emerge at the tachyon vacuum. It seems very likely that our techniques could be used for efficient computation of off-shell string amplitudes in the $B_0$ gauge, which would be much simpler than those in the Siegel gauge.

In this paper we focused solely on the open bosonic string field theory. It seems quite possible that our methods extend to the Berkovits superstring field theory, since it is based on Witten’s associative star product. On the other hand, for closed string field theory [59], we are much less optimistic because of the multitude of higher order vertices and especially because of the level matching condition $b_0^6\Psi = 0$, which does not fit well into our algebraic framework. So far all attempts to eliminate the level matching condition, or put it on the same footing as a gauge choice have been unsuccessful.

**Acknowledgments**

I am grateful to Ian Ellwood for collaboration at the initial stages of this work. I am indebted to Barton Zwiebach for useful discussions and especially for detailed reading of the manuscript which helped clarify many issues and improve the presentation. I would also like to thank organizers of Benasque Center for Science workshop on string theory for providing lovely environment while this work was in progress.
A Comments on surface states

The wedge states discussed extensively in section 2 are a prime example of more general surface states [54, 16]. The surface states are in one-to-one correspondence with conformal maps \( f(z) \) holomorphic inside the unit disk \( |z| < 1 \). They are defined by the relation

\[
\langle f | \phi \rangle = \langle f \circ \phi \rangle , \quad \forall \phi .
\] (A.1)

In the operator formalism they can be expressed as \( \langle f | = \langle 0 | U_f \), where \( U_f = \exp(\sum v_n L_n) \) is an exponential of non-negatively moded Virasoro generators. The coefficients \( v_n \) can be thought of as Laurent coefficients of a vector field \( v(z) = \sum v_n z^{n+1} \) which is related to the map \( f(z) \) by the Julia equation \( v(z) \partial_z f(z) = v(f(z)) \). In practise, given \( v(z) \) the equation is fairly easy to integrate to find \( f(z) \) [67], the inverse problem is much harder and usually one has to resort to an iterative procedure to determine the coefficients of the vector field. One class of solutions [58] is particularly useful however, the maps

\[
f_{n,t}(z) = \frac{z}{(1 - tnz^n)^{1/n}}
\] (A.2)

are generated by a vector field \( v(z) = tz^{n+1} \), so that \( U_{f_{n,t}} = e^{tL_n} \). These maps played pivotal role recently in the study of butterfly projectors [68, 69, 67] within the context of vacuum string field theory.

Apart of their importance for the butterfly projectors these maps can be taken as some kind of a basis for holomorphic maps. Any map \( f(z) \) holomorphic at the origin \( z = 0 \) and vanishing there can be uniquely decomposed as

\[
f(z) = f_{0,0} \circ f_{1,t_1} \circ f_{2,t_2} \circ \ldots .
\] (A.3)

In a sense this is a complete parametrization of the space of conformal maps holomorphic at the origin.\footnote{There is also another, as far as we can see unrelated, parametrization of this space using harmonic moments which can be thought of as times of dispersionless Toda hierarchy. This has been applied to the study of wedge states [70] and of the three-vertex [71].} Given a power series expansion around the origin, this decomposition is unique. It can be easily implemented on a computer since \( f_{n,t} = z + tz^{n+1} + O(z^{2n+1}) \). The decomposition (A.3) is useful because using the composition rule \( U_{f \circ g} = U_f U_g \) (reflecting the fact that \( U_f \) form a representation of the conformal group) the operator \( U_f \) can be written as

\[
U_f = e^{t_0 L_0} e^{t_1 L_1} e^{t_2 L_2} \ldots .
\] (A.4)

For the surface states \( \langle f | = \langle 0 | U_f \) the first two exponentials are of course irrelevant. Expanding the other exponentials in powers of \( L_n \) yields automatically canonically ordered form

\[
\langle f | = \sum \frac{k_2 k_3 k_4 \ldots}{k_2! k_3! k_4! \ldots} \langle 0 | L_2^{k_2} L_3^{k_3} L_4^{k_4} \ldots ,
\] (A.5)
which is very useful in level truncation. This decomposition was found to take very simple form for the identity state \[25\] and also for the 'nothing state' projector in \[69, 67\].

For the purposes of the present paper, where we use at several occasions the level truncation to check and illustrate certain exact computations, we need a decomposition (A.4) for the wedge states. With the help of a computer we easily find for \(f_r = \tan(\frac{2}{r} \arctan z)\)

\[
U_r \equiv U_{f_r} = \left(\frac{2}{r}\right)^L e^{u_2 L_2} e^{u_4 L_4} e^{u_6 L_6} e^{u_8 L_8} e^{u_{10} L_{10}} \ldots, \tag{A.6}
\]

where the coefficients \(u_n\) are given by

\[
\begin{align*}
  u_2 &= -\frac{r^2 - 4}{3r^2} \\
  u_4 &= \frac{r^4 - 16}{30r^4} \\
  u_6 &= -\frac{16(r^2 - 4)(r^2 - 1)(r^2 + 5)}{945r^6} \\
  u_8 &= \frac{(r^2 - 4)(109r^6 + 436r^4 - 944r^2 + 1344)}{11340r^8} \\
  u_{10} &= -\frac{16(r^2 - 4)(r^2 - 1)(9r^6 + 45r^4 - 64r^2 + 160)}{22275r^{10}}.
\end{align*}
\tag{A.7}
\]

Note that all the coefficients vanish for \(r = 2\), i.e. the vacuum, but also \(u_6 = u_{10} = 0\) for \(r = 1\) in accord with the observation of Ellwood et al. \[25\].

**Conservation laws**

Conservation laws in string field theory are quite a useful tool. We use them to tell us what is the action of a given mode of an arbitrary operator on a surface state, or any kind of \(n\)-vertex. They were first studied systematically by Rastelli and Zwiebach in \[54\], although some of them appeared in the literature much earlier. In what follows we will be mainly interested in the so called Virasoro conservation laws associated with the energy-momentum tensor and for simplicity we shall assume zero central charge.

The basic conservation laws for arbitrary surface state \(\langle f \rangle = \langle 0 | U_f\) can be written trivially as

\[
\langle f | f^{-1} \circ L_{-n} = 0 \tag{A.8}
\]

since \(f^{-1} \circ L_{-n} = U_f^{-1} L_{-n} U_f\) and \(L_{-n}\) annihilates the vacuum \(\langle 0 \rangle\). In the language of \[54\] one would write

\[
\langle f | \oint v^w(w) T_{ww}(w) dw = 0 \tag{A.9}
\]

for any vector field in the global coordinate \(w\) that is holomorphic everywhere including infinity except possibly the puncture. Transforming to the local coordinate \(z\) gives

\[
\langle f | \oint v^z(z) T_{zz}(z) dz = 0. \tag{A.10}
\]
Using the transformation law for the vector field $v^z(z) = (f'(z))^{-1} v^w(w)$ one finds conservation laws

$$\langle f \mid \oint \frac{dw}{2\pi i} f'(w)^{-n+1} \sum_{m=-n}^{\infty} \frac{L_m}{w^{m+2}} \rangle = 0, \quad (A.11)$$

which are identical to (A.8). An example of such conservation laws for the sliver was given in (2.40).

The disadvantage of this form of conservation laws is that it expresses an action of an operator $L_n$ for $n \geq -1$ not as a sum of operators $L_k$ with $k \leq -2$ acting on $|f\rangle$ but it involves also operators $L_k$ with $-2 < k < n$, for which one would like to use the conservation laws again. It is clearly desirable to have more direct way of writing the conservation laws one needs.

There is actually a trick to do that. The key observation is that the $b(z)$ ghost has the same conservation laws as the energy-momentum tensor $T(z)$ with zero central charge. For the $b$ ghost the conservation laws in the right form follow readily from the Neumann matrix representation. Thus the task is reduced to find the Neumann matrix such that in the ghost sector

$$\langle f |_{\text{ghost}} = \langle 0 | e^{\sum c_p S_{pq} b_q}. \quad (A.12)$$

There is a simple way to do it. We can simply evaluate the correlator

$$\langle f | b_{-n} c_{-m} c \partial c \partial^2 c(0) | 0 \rangle \quad (A.13)$$

in two different ways and match the results. Using the fact that $\langle f \rangle = \langle 0 | U_f$ and performing the conformal transformation on the ghosts we find

$$\langle f | b(z) c(w) c \partial c \partial^2 c(0) | 0 \rangle = \frac{(f'(z))^2}{f'(w)} \left( \frac{f(w)}{f(z)} \right)^3 \frac{2}{f(w) - f(z)}. \quad (A.14)$$

and therefore

$$\langle f | b_{-n} c_{-m} c \partial c \partial^2 c(0) | 0 \rangle = \oint \frac{dz}{2\pi i} \oint \frac{dw}{2\pi i} \frac{1}{z^{n-1}} \frac{1}{w^{m+2}} \left( \frac{f'(z)}{f'(w)} \right)^3 \frac{2}{f(w) - f(z)}. \quad (A.15)$$

On the other hand using the normalization $\langle c \partial c \partial^2 c(0) \rangle = -2$ (i.e. $\langle c_{-1} c_0 c_1 \rangle = 1$) we get

$$\langle 0 | e^{\sum c_p S_{pq} b_q} b_{-n} c_{-m} c \partial c \partial^2 c(0) | 0 \rangle = 2 S_{nm}, \quad (A.16)$$

and hence

$$S_{nm} = \oint \frac{dz}{2\pi i} \oint \frac{dw}{2\pi i} \frac{1}{z^{n-1}} \frac{1}{w^{m+2}} \left( \frac{f'(z)}{f'(w)} \right)^3 \frac{1}{f(w) - f(z)}, \quad (A.17)$$

25I thank Barton Zwiebach for suggesting the method.
The conservation laws then read

\[ \langle f | b_n \rangle = -\sum_{m=2}^{\infty} S_{nm} \langle f | b_{-m} \rangle, \quad (A.18) \]

\[ \langle f | L_n \rangle = -\sum_{m=2}^{\infty} S_{nm} \langle f | L_{-m} \rangle. \quad (A.19) \]

One application where we used the conservation laws \( (A.19) \) was to test the frequently used conservation law for the wedge states

\[ L_0|\tau\rangle = \frac{2-r}{r} L_0^1|\tau\rangle, \quad (A.20) \]

which follows directly from \( (2.57) \). This conservation law can be also derived following Rastelli and Zwiebach using a vector field

\[ v^w(w) = 2(1 + w^2) \arccot w. \quad (A.21) \]

This vector field is not globally defined, but is holomorphic everywhere outside the unit circle including the infinity, so that \( (A.9) \) still holds for a contour encircling the infinity. By deforming the contour onto the unit circle and passing to the local coordinate one finds

\[ v^z(z) = (r - 2)(1 + z^2) \arctan z + r(1 + z^2) \arccot z \quad (A.22) \]

from which

\[ \langle \tau | (rL_0^1 + (r - 2)L_0) \rangle = 0 \quad (A.23) \]

follows, and hence also \( (A.20) \). Although we have derived or proved \( (A.20) \) in many ways we wanted to see whether it really works in level truncation. Using \( (A.19) \) we calculated the \( L_{-2} \) coefficient of \( L_0|\tau\rangle \) and compared with the expected result \( \frac{8(2-r)}{3r^2} L_{-2}|0\rangle + \cdots \) from the right hand side of \( (A.20) \). The numerical agreement turned out to be quite good for finite \( r \), but for \( r \) set to infinity \( L_0|\infty\rangle \) did not seem to converge, although formally it can be set to zero. This only stresses the importance of the observation made in section 3 and further discussed in appendix C that the sliver and the sum part of \( (3.15) \) cancel each other to a large extent.
B Bernoulli numbers

The Bernoulli numbers are among the most important number sequences in number theory. They are defined through

\[
\frac{x}{e^x - 1} = \sum_{n=0}^{\infty} \frac{B_n x^n}{n!}.
\]  

(B.1)

The first few nontrivial numbers are \( B_0 = 1, B_1 = -\frac{1}{2}, B_2 = \frac{1}{6}, B_4 = -\frac{1}{30}, B_6 = \frac{1}{42}, B_8 = -\frac{1}{30}, B_{10} = \frac{5}{66}, B_{12} = -\frac{691}{2730}, \ldots \) The obey number of remarkable properties, the most basic ones are

\[
B_{2k+1} = 0, \quad \forall k \geq 1
\]  

(B.2)

\[
\sum_{k=0}^{n} \frac{B_k}{k!} \frac{1}{(n + 1 - k)!} = 0, \quad \forall n \geq 1.
\]  

(B.3)

Well known is also the Euler identity

\[
(n + 1)B_n = -\sum_{k=2}^{n-2} \frac{n!}{k!(n-k)!} B_k B_{n-k}, \quad \forall n \geq 3.
\]  

(B.4)

There are number of other linear, quadratic or higher order identities [72]. It appears however that the ones we have discovered by solving the string field theory equations of motion were previously unknown. The first one is quite similar to the Euler identity

\[
(n - 1)B_n = -\sum_{0 \leq p, q \leq n} \frac{n!}{p!q!(n-p-q)!} B_p B_q, \quad \forall n \geq 0.
\]  

(B.5)

A simple proof using (B.3) goes as follows. Let us write the right hand side of (B.5) as

\[
-B_n - \sum_{q=0}^{n-1} \sum_{p=0}^{n-q} \frac{n!(n-p-q+1)}{plq!(n-p-q+1)!} B_p B_q = -B_n + \sum_{q=0}^{n-1} \sum_{p=1}^{n-q} \frac{n!}{(p-1)!q!(n-p-q+1)!} B_p B_q =
\]

\[
-B_n + \sum_{p=1}^{n} \sum_{q=0}^{n-p} \frac{n!}{(p-1)!q!(n-p-q+1)!} B_p B_q = (n-1)B_n.
\]

In the first sum only the \(-p\) term from the factor \((n-p-q+1)\) in the numerator was contributing thanks to (B.3). In the last sum only \(p = n, q = 0\) term was contributing thanks to the same identity.

Another important fact about Bernoulli numbers we need, is their asymptotics

\[
B_{2k} = 2(-1)^{k-1} \frac{(2k)!}{(2\pi)^{2k}} \zeta(2k) = 2(-1)^{k-1} \frac{(2k)!}{(2\pi)^{2k}} \left( 1 + O \left( 2^{-2k} \right) \right).
\]  

(B.6)
C Proof of the sum-sliver cancellation

In this appendix we shall apply the Euler–Maclaurin formulato establish rigorous lower bound on positive constant \( A_p \) such that

\[
\sum_{k=2}^{\infty} \left. \frac{d}{d\alpha} \left[ 1 - \left( \frac{2}{k + \alpha} \right)^p \right]^M \right|_{\alpha=0} = 1 + O\left( e^{-A_p M^{1/(p+1)}} \right). \tag{C.1}
\]

This in turn will imply the estimates (3.21, 3.22) proving thus the cancellation between the two terms in \( |\infty⟩ - \sum_{n=2}^{\infty} \partial_n |n⟩ \) for two classes of high level coefficients, namely \((L−2)^M |0⟩\) and \((L−4)^M |0⟩\).

The Euler–Maclaurin formula states that (see e.g. [73, 74])

\[
\sum_{k=a}^{b} f(k) = \sum_{n=0}^{N} \frac{B_n}{n!} \left[ f^{(n-1)}(b) - f^{(n-1)}(a) \right] + R_N, \tag{C.2}
\]

where \( B_n \) are the Bernoulli numbers (see appendix B), and by \( f^{(-1)} \) we denote the primitive function \( \int f(t)dt \). The remnant \( R_N \) for arbitrary \( N \) is given by

\[
R_N = \frac{1}{N!} \int_{a}^{b} B_N(t-[t])f^{(N)}(t)dt, \tag{C.3}
\]

where \( B_n(x) \) are the Bernoulli polynomials and \([t]\) denotes the integer part of \( t \). For a given function, the Euler–Maclaurin formula is typically useful only up to certain maximal \( N \) which minimizes the error. This is because of the eventual factorial growth of the Bernoulli numbers and polynomials.\(^{26}\)

Applying the formula (C.2) to our sum and taking the harmless limit \( b \to \infty \) we see that for \( 0 < n \leq N < M \) the \((n-1)\)-th derivatives of our function \( f(t) = \partial_t \left[ 1 - \left( \frac{2}{t} \right)^p \right]^M \) all vanish at \( t = 2 \) and \( t = \infty \). Thus it is only the first term in (C.2) with \( n = 0 \) and the remnant \( R_N \) which contribute. For the upper bound on the remnant one can use \( |B_N(x)| \leq |B_N| \) for \( x \in [0, 1] \) for \( N \) even and hence

\[
|R_N| \leq \frac{|B_N|}{N!} \int_{2}^{\infty} |f^{(N)}(t)|dt. \tag{C.4}
\]

The strategy is now to find a value of \( N, 0 < N < M \) such that \( |R_N| \) is minimized. For that we need accurate estimate of \( \int_{2}^{\infty} |f^{(N)}(t)|dt \) which is actually the hardest part of the proof.

Naive expansion of \( \frac{d^{N+1}}{dt^{N+1}} \left[ 1 - \left( \frac{2}{t} \right)^p \right]^M \) into the binomial series, taking the absolute value of each term and integrating it, wouldn’t work. The estimate would be too crude and useless, since it would not take into account that at \( t = 2 \) the integrand vanishes.

\(^{26}\)The Euler–Maclaurin formula written for infinite \( N \) without a remnant in most cases presents an asymptotic series which can be summed via Borel summation technique [92]. The cases when the series converges by itself are rare and the most prominent examples are polynomials and exponentials.
Let us start with the formula for derivative of a composite function

\[
\frac{d^n}{dx^n} F(\phi(x)) = \sum_{m=0}^{n} \frac{n!}{\prod_{j} p_j!} \left( \phi^{(j)}(x) \right)^{p_j} \sum_{\sum p_j = n} \prod_{j} \left( \frac{d^{m_j} y}{dy^{m_j}} \right) \left( \phi(\phi_j(x)) \right)^{p_j}. \quad (C.5)
\]

Inserting the identity in the forms of 1 = \(\oint \frac{dz}{2\pi i} z^{n+1} \prod_j z^{p_j} \) and 1 = \(\oint \frac{dw}{2\pi i} w^{m+1} \prod_j w^{p_j} \), and performing the sum over all \(p_j\)’s we find

\[
\frac{d^n}{dx^n} F(\phi(x)) = n! \sum_{m=0}^{n} \frac{d^m F}{dy^m} \oint \frac{dz}{2\pi i} \frac{1}{z^{n+1}} \frac{1}{m!} \left[ \phi(x + z) - \phi(x) \right]^m. \quad (C.6)
\]

Let us set \(F(y) = y^M, \phi(x) = 1 - (\frac{x}{2})^p\) and assume \(n > 0\). Then by using \(\phi(x + z) - \phi(x) = (\frac{x}{2})^p \left[ 1 - (1 + \frac{x}{2})^{-p} \right]\) and with the help of binomial expansion for the \(m\)-th power, we find easily by direct integration

\[
\int_2^{\infty} \left| \frac{d^n}{dx^n} \left[ 1 - \left( \frac{2}{x} \right)^p \right]^M \right| \leq \frac{M! 2^{-n+1} p^{-1}}{\Gamma(M + n - 1/p + 1)} \sum_{m=1}^{n} \sum_{k=1}^{m} \frac{\Gamma\left(m + \frac{n-1}{p}\right)}{k!(m-k)!(pk-1)!}. \quad (C.7)
\]

The double sum on the right hand side can be replaced by the maximal term times a factor of \(n^2\) which is not going to affect the leading behavior. The maximum is achieved for \(m = n\) and \(k = c_p n\) where \(c_p\) is a solution to

\[
\left( 1 + \frac{1}{pc_p} \right)^p = \frac{c_p}{1 - c_p},
\]

i.e. \(c_2 = 0.738, c_4 = 0.758\) for the cases of interest. Now setting \(n = N + 1\), using \(B_N/N! \sim (2\pi)^{-N}\) we can minimize the remnant. The minimum is attained for \(n \propto M^{1/(p+1)}\) and by calculating the exact coefficient we find

\[
|R_N| \leq K_p e^{-A_p M^{1/(p+1)}}, \quad (C.8)
\]

where \(K_p\) is some finite constant and \(A_p = \left(4\pi \frac{1-c_p}{1+pc_p}\right)^{p/(p+1)}\). Again for the cases of interest we find \(A_2 = 1.210\) and \(A_4 = 0.799\) which seem to be smaller by a factor of four from what numerical fits would suggest. To obtain more precise estimate of \(A_p\) and not just upper bound would be more challenging, since \(B_N(t - [t])\) is a periodic function and large cancellations in \(C.3\) are taking place. Anyway it is nice, that apart of proving an upper bound we were able to capture the qualitative behavior, i.e. the power of \(M^{1/(p+1)}\) in the exponent.
D Collection of useful formulas

D.1 $\mathcal{B}_0$-gauge formulas

We define

\[ B_0 = \oint \frac{d\bar{z}}{2\pi i} \bar{z} b_{\bar{z}}(\bar{z}) = \tan \circ b_0 = b_0 + \sum_{k=1}^{\infty} \frac{2(-1)^{k+1}}{4k^2 - 1} b_{2k} = b_0 + \frac{2}{3} b_2 - \frac{2}{15} b_4 + \cdots \quad (D.1) \]

\[ B_0^L = \oint \frac{d\bar{z}}{2\pi i} \bar{z} b_{\bar{z}}(\bar{z}) = b_0 + \sum_{k=1}^{\infty} \frac{2(-1)^{k+1}}{4k^2 - 1} b_{-2k} = b_0 + \frac{2}{3} b_{-2} - \frac{2}{15} b_{-4} + \cdots \quad (D.2) \]

\[ B_1 = \oint \frac{d\bar{z}}{2\pi i} \bar{z} b_{\bar{z}}(\bar{z}) = b_1 + b_{-1} \quad (D.3) \]

\[ B_1^L = \oint_{C_L} \frac{d\bar{z}}{2\pi i} b_{\bar{z}}(\bar{z}) = \frac{1}{2} B_1 + \frac{1}{\pi} \left( B_0 + B_0^L \right) \quad (D.4) \]

\[ B_1^R = \oint_{C_R} \frac{d\bar{z}}{2\pi i} b_{\bar{z}}(\bar{z}) = \frac{1}{2} B_1 - \frac{1}{\pi} \left( B_0 + B_0^L \right) \quad (D.5) \]

where the open contours $C_L$ and $C_R$ are the left half ($\text{Re} \, \bar{z} > 0$) and the right half ($\text{Re} \, \bar{z} < 0$) of the unit circle. These objects clearly satisfy $B_1^L + B_1^R = B_1$ and further

\[ B_1^L (\phi_1 * \phi_2) = (B_1^L \phi_1) * \phi_2, \quad (D.6) \]

\[ B_1^R (\phi_1 * \phi_2) = (-1)^{\text{gn}(\phi_1)} \phi_1 * (B_1^R \phi_2), \quad (D.7) \]

\[ B_1 (\phi_1 * \phi_2) = (B_1 \phi_1) * \phi_2 + (-1)^{\text{gn}(\phi_1)} \phi_1 * (B_1 \phi_2). \quad (D.8) \]

The first two equations are manifestations of the fact that Witten’s star product glues together right part of the first string with the left part of the second string, so that $B_1^L$ acting on the first string can be pulled out of the product. Same is true for $B_1^R$ on the second string with appropriate Grassman sign. The last equation tells us, that $B_1$ is a graded derivation of the star algebra.

We also frequently need to commute $B_0^L$ through the operator $U_r = (2/r)^{\xi_0}$, or $B_0$ through $U_r^{\dagger}$

\[ U_r B_0^L U_r^{-1} = \frac{2-r}{r} B_0 + \frac{2}{r} B_0^L, \]

\[ U_r^{\dagger} B_0 U_r^{\dagger-1} = \frac{2}{r} B_0 + \frac{2-r}{r} B_0^L, \]

\[ U_r^{-1} B_0^L U_r = \frac{r-2}{2} B_0 + \frac{r}{2} B_0^L, \]

\[ U_r^{\dagger} B_0 U_r^{\dagger-1} = \frac{r}{2} B_0 + \frac{r-2}{2} B_0^L. \quad (D.9) \]

Useful anticommutators are

\[ \{ B_0, \bar{c}(\bar{z}) \} = \bar{z}, \]

\[ \{ B_1, \bar{c}(\bar{z}) \} = 1. \quad (D.10) \]
D.2 Some correlators

Using the definitions \( \tilde{c}(x) = \cos^2(x) c(\tan x) \) and the fact that inversion acts simply as a translation \( I \circ \tilde{c}(x) = \tilde{c}(x - \pi/2) = \tilde{c}(x + \pi/2) \) we readily derive\(^\text{27}\)

\[
\begin{align*}
\langle \tilde{c}(x) \tilde{c}(y) \tilde{c}(z) \rangle &= \sin(x - y) \sin(x - z) \sin(y - z), \\
\langle I \circ \tilde{c}(x) \tilde{c}(y) \tilde{c}(z) \rangle &= \cos(x - y) \cos(x - z) \sin(y - z), \\
\langle I \circ \tilde{c}(x) I \circ \tilde{c}(y) \tilde{c}(z) \rangle &= \sin(x - y) \cos(x - z) \cos(y - z), \\
\langle I \circ \tilde{c}(x) I \circ \tilde{c}(y) I \circ \tilde{c}(z) \rangle &= \sin(x - y) \sin(x - z) \sin(y - z), \\
\langle \tilde{c}(x) \tilde{c} \partial \tilde{c}(y) \rangle &= -\sin(x - y)^2, \\
\langle I \circ \tilde{c}(x) \tilde{c} \partial \tilde{c}(y) \rangle &= -\cos(x - y)^2. \quad (D.11)
\end{align*}
\]

Useful correlators involving the \( \mathcal{B}_0 + \mathcal{B}_0^\dagger \) operator are

\[
\begin{align*}
\langle I \circ \tilde{c}(x) I \circ \tilde{c}(-x) \left( \mathcal{B}_0 + \mathcal{B}_0^\dagger \right) \tilde{c}(y) \tilde{c}(-y) \rangle &= 2y \sin(2x) \cos(x + y) \cos(x - y) + 2x \sin(2y) \cos(x + y) \cos(x - y) \quad (D.12) \\
\langle I \circ \tilde{c}(x) I \circ \tilde{c}(-x) \left( \mathcal{B}_0 + \mathcal{B}_0^\dagger \right) \tilde{c} \partial \tilde{c}(y) \rangle &= -x \left( \cos^2(x + y) + \cos^2(x - y) \right) + (y \partial_y - 1) \sin(2x) \cos(x - y) \cos(x + y). \quad (D.13)
\end{align*}
\]

Evaluating the above correlators for particular modes is not necessarily a simple task. We can use \( \langle c_{-1} c_0 c_1 \rangle = 1 \) and

\[
\begin{align*}
\tilde{c}_{-2k} &= (-1)^k \frac{2^{2k}}{(2k + 1)!} c_0 + \cdots, \\
\tilde{c}_{-(2k-1)} &= (-1)^k \frac{2^{2k}}{(2k)!} \frac{c_1 - c_{-1}}{2} + \delta_{k,0} \frac{c_1 + c_{-1}}{2} + \cdots, \quad (D.14)
\end{align*}
\]

where the dots indicate modes other than \( c_{-1}, c_0 \) and \( c_1 \). We then find

\[
\langle (\tilde{c}_p)^\dagger Q_B \tilde{c}_{-q} \rangle = \frac{2^{p+q+1}}{(p+1)!(q+1)!} (-1)^{\frac{p+q}{2}} - \frac{1}{2} \delta_{p,-1} \delta_{q,-1}. \quad (D.15)
\]

Assuming \( p_1 \) and \( q_1 \) to be odd and \( p_2 \) and \( q_2 \) to be even we find further:

\[
\begin{align*}
\langle (\tilde{c}_{-p_1})^\dagger \tilde{c}_{-q_1} \tilde{c}_{-q_2} \rangle &= -(-1)^{\frac{p_1}{2}} \frac{2^{q_2}}{(q_2 + 1)!} \left[ \delta_{q_1,-1} \left( \frac{2^{p_1}}{(p_1 + 1)!} \right) (-1)^{\frac{p_1+1}{2}} + \delta_{p_1,-1} \left( \frac{2^{q_1}}{(q_1 + 1)!} \right) (-1)^{\frac{q_1+1}{2}} \right], \quad (D.16) \\
\langle (\tilde{c}_{-p_1})^\dagger (\tilde{c}_{-p_2})^\dagger \left( \mathcal{B}_0 + \mathcal{B}_0^\dagger \right) \tilde{c}_{-q_1} \tilde{c}_{-q_2} \rangle &= -\left[ \delta_{p_2,0} (-1)^{\frac{q_2}{2}} \frac{2^{q_2}}{(q_2 + 1)!} + \delta_{q_2,0} (-1)^{\frac{p_2}{2}} \frac{2^{p_2}}{(p_2 + 1)!} \right] \left[ \delta_{p_1,-1} \frac{2^{q_1}}{(q_1 + 1)!} (-1)^{\frac{q_1+1}{2}} + \delta_{q_1,-1} \frac{2^{p_1}}{(p_1 + 1)!} (-1)^{\frac{p_1+1}{2}} \right]. \quad (D.17)
\end{align*}
\]

\(^\text{27}\)All the correlators are taken on the upper half-plane. Also, it would be more consistent with our previous notation if all \( x, y \) and \( z \) had a tilde.
E  Details for ghost number one equation of motion

In this appendix we provide few intermediate steps for plugging the ansatz \( \Psi \) into the equation of motion \( Q_B \Psi + \Psi \Psi = 0 \). The action of the BRST charge \( Q_B \) is quite simple, since it annihilates the vacuum, commutes with \( \widehat{L} \) and its anticommutator with \( \widehat{B} \) is \( \widehat{L} \).

Least obvious is perhaps the action on the \( \tilde{c} \) ghost \( \{ Q_B, \tilde{c}(\tilde{z}) \} = \tilde{c}\tilde{\partial}\tilde{c}(\tilde{z}) \), which takes the same form as in the \( z \) coordinate. For the first term in the equation of motion we find easily

\[
Q_B \Psi = \sum_{n,k,l} \left[ \frac{k - l}{2} f_{n,k+l} + f_{n-1,k,l} \right] \widehat{L}^n \tilde{c}_k \tilde{c}_l |0\rangle - \widehat{B} \sum_{n,k,l,q} (k - l) f_{n,k+l,q} \widehat{L}^n \tilde{c}_k \tilde{c}_l |q\rangle. \tag{E.1}
\]

For the second term \( \Psi \Psi \) we use results from section \[25] Denoting the two terms in \[1,2a\] as \( \Psi = \Psi^{(1)} + \Psi^{(2)} \), the second one containing the \( (B_0 + \tilde{B}_0) \) factor, we find

\[
\Psi^{(1)} \Psi^{(1)} = \sum_{N,n,m,l,p,q} (-1)^k \left( \frac{\pi}{4} \right)^{k+l} D^N_{n,m,l,k} \left( k + p - 2 \right) \left( l + q - 2 \right) f_{n+k+p,m+l+q} \widehat{L}^n \tilde{c}_p \tilde{c}_q |0\rangle \tag{E.2}
\]

\[
\Psi^{(1)} \Psi^{(2)} = \frac{\pi}{2} \sum_{N,n,m,l,p,q} (-1)^k \left( \frac{\pi}{4} \right)^{k+l} D^N_{n,m,k,l,0} \left( k + p - 2 \right) \left( l + q - 2 \right) f_{n+k+l,m,q} \widehat{L}^n \tilde{c}_p \tilde{c}_q |0\rangle +
\]

\[
\sum_{N,n,m,k,k+l,p,q} \left( \frac{\pi}{4} \right)^{k+l} \left( k_1 + k_2 + l \right) (-1)^{k_1} D^N_{n,m,k,l,k_1} f_{n+p+k,l} \widehat{L}^n \tilde{c}_p \tilde{c}_q |0\rangle
\]

\[
\left( \frac{k_1 + p_1 - 2}{k_1} \right) \left( \frac{k_2 + p_2 - 2}{k_2} \right) \left( l + q - 2 \right) \widehat{L}^n \tilde{c}_p \tilde{c}_q |0\rangle \tag{E.3}
\]

\[
\Psi^{(2)} \Psi^{(1)} = \frac{\pi}{2} \sum_{N,n,m,l,p,q} (-1)^k \left( \frac{\pi}{4} \right)^{k+l} D^N_{n,m,0,k+l} \left( k + p - 2 \right) \left( l + q - 2 \right) f_{n+k+q,m,l} \widehat{L}^n \tilde{c}_p \tilde{c}_q |0\rangle +
\]

\[
\sum_{N,n,m,k,k+l,p,q} \left( \frac{\pi}{4} \right)^{k+l} \left( k_1 + k_2 + l \right) (-1)^{k_1+l} D^N_{n,m,k,l,k_1} f_{n+p+k,q} \widehat{L}^n \tilde{c}_p \tilde{c}_q |0\rangle
\]

\[
\left( \frac{k_1 + p_1 - 2}{k_1} \right) \left( \frac{k_2 + p_2 - 2}{k_2} \right) \left( l + q - 2 \right) \widehat{L}^n \tilde{c}_p \tilde{c}_q |0\rangle \tag{E.4}
\]

\[
\Psi^{(2)} \Psi^{(2)} = \pi^2 \sum_{N,n,m,q_1,q_2,l_1,l_2} (-1)^{l_1} \left( \frac{\pi}{4} \right)^{l_1+l_2} D^N_{n,m,l_1,l_1} \left( l_1 + q_1 - 2 \right) \left( l_2 + q_2 - 2 \right) f_{n+q_1,m,l_2} \widehat{L}^n \tilde{c}_q \tilde{c}_q |0\rangle +
\]

\[
- \frac{\pi}{2} \sum_{N,n,m,p_1,p_2,q_1,q_2,k_1,k_2,l_1,l_2} \left( \frac{\pi}{4} \right)^{k_1+l_1+k_2+l_2} (-1)^{k_1+l_1} D^N_{n,m,k_1,k_2,l_1,l_2} f_{n+p_1+l_1,k_1} f_{n+p_2+q_1} \widehat{L}^n \tilde{c}_p \tilde{c}_q |0\rangle \times
\]

\[
\left( \frac{k_1 + p_1 - 2}{k_1} \right) \left( \frac{l_1 + q_1 - 2}{l_1} \right) \left( \frac{k_2 + p_2 - 2}{k_2} \right) \left( l_2 + q_2 - 2 \right) \widehat{B} \widehat{B} \widehat{L}^n \tilde{c}_p \tilde{c}_q \tilde{c}_q |0\rangle. \tag{E.5}
\]
where
\[
D_{n,m,k,l}^{N} = \frac{n!m!}{N!} (2)^{n+m-N} \int \frac{dr}{2\pi i} \int \frac{ds}{2\pi i} (r + s - 3)^{N} (r - 2)^{n+1} (s - 2)^{n+1} (r - 1)^{k} (s - 1)^{l}
\]
\[
= \frac{n!m!}{N!} (2)^{n+m-N} \sum_{j=0}^{N} \binom{N}{j} \binom{k}{n-j} \binom{N-j+l}{m}.
\]  
(E.6)

Although the twelve-fold sum with up to seven binomial factors looks prohibitively complicated, it is actually quite easy to plug the expressions to the computer. Imposing twist symmetry, i.e. \( f_{n,p} = 0 \) for \( p \) even and \( f_{n,p,q} = 0 \) for \( p + q \) even, we find
\[
0 = f_{0,1} + \pi \left[ \frac{1}{2} f_{0,1}^{2} + f_{0,1} (f_{1,1} + 2f_{0,1,0}) \right]
\]  
(E.7)

\[
0 = f_{1,1} + 2f_{0,1,0} + \pi \left[ \frac{1}{4} f_{0,1}^{2} - \frac{3}{2} f_{0,1} f_{1,1} - f_{0,1} f_{0,1,0} + f_{1,1}^{2} + 2f_{1,1} f_{0,1,0} + 2f_{0,1} (f_{2,1} + f_{1,1,0}) \right]
\]
\[
0 = f_{2,1} + 2f_{1,1,0} + \pi \left[ -\frac{1}{16} f_{0,1}^{2} + \frac{5}{8} f_{0,1} f_{1,1} - f_{1,1}^{2} - 2f_{0,1} f_{2,1} + 3f_{1,1} f_{2,1} + f_{0,1} (3f_{3,1} + 2f_{2,1,0}) + \frac{1}{4} f_{0,1} f_{0,1,0} - f_{1,1} f_{0,1,0} + 2f_{2,1} f_{0,1,0} - f_{0,1} f_{1,1,0} + 2f_{1,1} f_{1,1,0} \right]
\]
\[
0 = f_{0,-1} + \pi \left[ \frac{1}{2} f_{0,1} f_{0,-1} + f_{0,1} (-f_{0,-1} + 2f_{0,0,-1}) \right] + \pi^{3} \left[ \frac{1}{32} f_{0,1}^{2} - \frac{3}{16} f_{0,1} f_{1,1} + \frac{1}{4} f_{1,1}^{2} + \frac{1}{4} f_{0,1} f_{2,1} - \frac{1}{2} f_{1,1} f_{2,1} + \frac{1}{8} f_{0,1} f_{0,1,0} - \frac{1}{2} f_{1,1} f_{0,1,0} + f_{2,1} f_{0,1,0} - f_{0,1} f_{2,1,0} + 2f_{0,1} f_{1,1,0} \right]
\]
\[
0 = 3f_{0,-1} + \pi \left[ -\frac{3}{2} f_{0,-1} f_{0,1} + 3f_{0,-1} f_{1,1} + 2f_{0,1} f_{0,1,-2} \right] + \pi^{3} \left[ -\frac{1}{32} f_{0,1}^{2} + \frac{3}{16} f_{0,1} f_{1,1} - \frac{3}{4} f_{0,1} f_{2,1} + \frac{3}{2} f_{0,1} f_{3,1} + \frac{3}{8} f_{0,1} f_{0,1,0} - \frac{3}{2} f_{1,1} f_{0,1,0} + 3f_{2,1} f_{0,1,0} \right]
\]  
\[
\ldots .
\]  
(E.8)

These equations are equations for the coefficients of \( \tilde{c}_{1} \tilde{c}_{0} |0\rangle, (\mathcal{L}_{0} + \mathcal{L}_{0}^{0}) \tilde{c}_{1} \tilde{c}_{0} |0\rangle, (\mathcal{L}_{0} + \mathcal{L}_{0}^{0})^{2} \tilde{c}_{1} \tilde{c}_{0} |0\rangle, \tilde{c}_{0} \tilde{c}_{-1} |0\rangle, \tilde{c}_{1} \tilde{c}_{-2} |0\rangle, \ldots \) in the equation of motion \( Q_{B} \Psi + \Psi \# \Psi = 0 \). It is interesting to see that imposing the \( B_{0} \) gauge condition
\[
f_{n,p,0} + \frac{n+1}{2} f_{n+1,p} = 0
\]  
(E.9)

eliminates all the terms in the round brackets, and therefore the equations become exactly solvable one after each other. We have proved this general pattern in section 4. For example the first equation implies
\[
f_{0,1} = \frac{2}{\pi}, \quad \text{or} \quad f_{0,1} = 0.
\]

In the first case \( f_{0,1} = \frac{2}{\pi} \) we readily find
\[
f_{1,1} = \frac{1}{2\pi}, \quad f_{2,1} = \frac{1}{24\pi}, \quad f_{0,-1} = \frac{\pi}{48}, \quad f_{3,1} = -\frac{4}{3\pi^{2}} f_{0,1,-2}
\]  
53
and so on. Continuing up to level 12, i.e. finding coefficients like \( f_{12,1} \), it is easy to guess the complete form

\[
f_{n,-p} = \frac{\pi^p}{2^n2^{p+1}n!}(-1)^n B_{n+p+1}, \quad p \text{ odd,} \tag{E.10}
\]

\[
f_{n,-p-q} = \frac{\pi^{p+q}}{2^{n+2(p+q)+3}n!}(-1)^{n+q} B_{n+p+q+2}, \quad p+q \text{ odd,} \tag{E.11}
\]

and hence (4.9) follows. The only proof that our guess is a true solution is given in section 4.1 using the wedge state representation. From the mathematical point of view, it would be interesting to find a direct proof using the form (4.9), since this would presumably lead to an infinite set of Euler–Ramanujan type of identities for Bernoulli numbers.

**Pure gauge solutions**

In the second case \( f_{0,1} = 0 \) we find \( f_{1,1} = \beta \) to be a free parameter which determines

\[
f_{2,1} = -\frac{\pi}{2} \beta^2, \quad f_{0,-1} = -\frac{\pi^3}{8} \beta^2.
\]

Going one step further we would find

\[
f_{3,1} = \frac{\pi}{8} \beta^2 + \frac{\pi}{4} \beta^3, \quad f_{1,-1} = \frac{3\pi^3}{16} \beta^2 + \frac{3\pi^4}{8} \beta^3, \quad f_{0,1,-2} = -\frac{3\pi^3}{32} \beta^2 - \frac{3\pi^4}{16} \beta^3.
\]

This solution clearly corresponds to a pure gauge. One particular value of \( \beta \) deserves perhaps a special attention. For \( \beta = -\frac{1}{2\pi} \) we found that all the terms \( f_{3,1}, f_{1,-1}, f_{0,1,-2} \) vanish, it seems that the solution shares the symmetry (4.43) with the tachyon solution. The other low level coefficients for this value of \( \beta \) are given by

\[
f_{2,1} = -\frac{1}{8\pi}, \quad f_{0,-1} = -\frac{\pi}{16};
\]

\[
f_{4,1} = \frac{1}{384\pi}, \quad f_{2,-1} = -f_{1,1,-2} = \frac{\pi}{128}, \quad f_{0,-3} = \frac{\pi^3}{256}.
\]

</tbody>
</table>

It is worth noticing that the coefficients of the states $L_{-2}^n c_1|0⟩$ decay quite rapidly, at a similar rate as in the Siegel gauge. This can be contrasted with identity based solution, where the decay is much slower, leading eventually to the divergence of the energy.
