Abstract

The description of dispersion forces within the framework of macroscopic quantum electrodynamics in linear, dispersive, and absorbing media combines the benefits of approaches based on normal-mode techniques of standard quantum electrodynamics and methods based on linear response theory in a natural way. It renders generally valid expressions for both the forces between bodies and the forces on atoms in the presence of bodies, while showing very clearly the intimate relation between the different types of dispersion forces. By considering examples, the influence of various factors like form, size, electric and magnetic properties, or intervening media on the forces is addressed. Since the approach based on macroscopic quantum electrodynamics does not only apply to equilibrium systems, it can be used to investigate dynamical effects such as the temporal evolution of forces on arbitrarily excited atoms.

Key words: dispersion force, macroscopic quantum electrodynamics, Casimir effect, van der Waals force, atom–surface interaction, intermolecular potential, atomic polarizability, magnetodielectric medium, multilayer structure, spontaneous decay, weak atom–field coupling, strong atom–field coupling, Rabi oscillation

1 Introduction

Dispersion forces originate from the electromagnetic interaction between electrically neutral objects which do not carry permanent electric and magnetic moments. They have been of increasing interest because of their important impact on many areas of science. In particular, the extremely miniaturized components in nanotechnology can be strongly affected by dispersion forces. Recent progress in experimental techniques have led to accurate measurements of dispersion forces, which have confirmed some of the theoretical predictions while posing new questions at the same time.

1.1 Dispersion forces

The prediction of dispersion forces is one of the most prominent achievements of quantum electrodynamics (QED), where they can be regarded as being a
consequence of quantum ground-state fluctuations. In order to understand how quantum fluctuations lead to dispersion forces, it may be helpful to first recall the corresponding classical situation. According to classical electrodynamics, electrically neutral, unpolarized material objects will not interact with each other, even if they are polarizable. An interaction can only occur if (i) at least one of the objects is polarized or (ii) an electromagnetic field is applied to at least one of the objects. In the former case the object’s polarization will give rise to an electromagnetic field, which can induce a polarization of the other polarizable object(s); in the latter case the applied field induces a polarization of the object, which in turn gives rise to an electromagnetic field acting on the other object(s). Both cases result in polarized objects interacting with each other via an electromagnetic field, the interaction and the resulting attractive forces between them being a consequence of the departure from the classical ground state—unpolarized objects and vanishing electromagnetic field.

In QED, the state that most closely corresponds to the classical ground state is given by the material objects being in their (unpolarized) quantum ground states and the electromagnetic field being in its vacuum state, such that both the electromagnetic field and the polarization of all objects vanish on the quantum average. At first glance, one could hence expect the absence of any interaction between the objects. However, the Heisenberg uncertainty principle necessarily implies the existence of ground state fluctuations, i.e., both (i) fluctuating polarizations of the objects and (ii) a fluctuating electromagnetic field will always be present. These fluctuations give rise to an interaction between the objects—a purely quantum effect which is manifested in the dispersion forces acting on them. At finite temperatures, additional thermal fluctuations come into play.

Thus, dispersion forces—also known as Casimir or van der Waals forces—^2—are ever-present long-range forces between atoms and/or macroscopic bodies, i.e., they exist even if the interacting objects are electrically neutral and do not carry electric or magnetic moments. Naturally, dispersion forces have many important consequences. On a microscopic level, they influence, e.g., the properties of weakly bound molecules [1, 2]. A prominent macroscopic signature of dispersion forces is the well-known correction to the equation of state of an ideal gas, leading to the more general van der Waals equation. ^3 But dispersion forces also influence the macroscopic properties of liquids and solids, such as the anomalies of water [4], the magnetic, thermal, and optical properties of solid oxygen [5], or the melting behavior of van der Waals crystals [6].

^2 Often, the term Casimir force is used to denote dispersion forces on a macroscopic level, whereas dispersion forces on a microscopic level are referred to as van der Waals forces.

^3 In fact, it was in this context that the existence of dispersion forces was first predicted, for a historical review, see Ref. [3].
The influence of dispersion forces becomes even more pronounced in the presence of interfaces between different phases and/or media. Atom-surface dispersion interactions drive the adsorption of inert gas atoms to solid surfaces [7,8,9], influence the wetting properties of liquids on such surfaces [8,10,11], and lead to the phenomenon of capillarity [12]. The mutual dispersion attractions of colloidal particles suspended in a liquid [13] influence the stability of such suspensions [14,15]; unless sufficiently balanced by repulsive forces, they lead to a clustering of the particles, commonly known as flocculation [16,17].

The abovementioned relevance of dispersion forces to material sciences and physical chemistry being rather obvious, it is perhaps more surprising to note that they also play a role in astrophysics and biology. Thus, dispersion forces initiate the preplanetary dust aggregation leading to the formation of planets around a star [18]. Furthermore, they are needed for an understanding of the interaction molecules with cell membranes [19,20] or of cell adhesion driven by mutual cell-membrane interactions [19,21]. Recently, dispersion forces have been found to be responsible for the remarkable abilities of some gecko [22] and spider species [23] to climb smooth, dry surfaces.

1.2 Experimental observations

A force between two macroscopic bodies can most easily be measured in a quasistatic way, where the bodies are brought close together and the force to be measured is compensated by a force of known magnitude. In the first use of this idea for measuring dispersion forces, the compensating force was provided by a Hookean spring and the distance of the bodies was measured by means of optical interferometry [24]. In this way, forces between two dielectric [24,25,26,27,28] or metallic plates [29,30,31,32] were investigated. Difficulties in aligning the plates were overcome by using alternative setups of a plate interacting with a spherical lens [28,33,34,35], two interacting spheres [36], or crossed cylinders [36,37]. Magnetic forces generated by electric currents were also used to compensate dispersion forces, where via feedback the force values could be inferred from current measurements [38,39,40,41]. The typical outcome of all these experiments was the observation of attractive forces, which follow $1/z^4$ and $1/z^3$ power laws for the plate–plate and plate–sphere geometries, respectively, with $z$ denoting the object–object separation (see Ref. [42] for a review). However, owing to the rather low accuracy—the main limitations being the presence of electrostatic forces due to residual charges, the roughness of the samples, the lack of accurate position control, and the low resolution of the actual force measurements—the early results remained controversial. This is best illustrated by the fact that differing power laws [25] and even signs [29] were found.

---

\[ \text{Note that the plate–sphere separation was much smaller than the sphere radius.} \]
Substantial progress was made by using a torsion-balance scheme [43], where very smooth bodies, piezoelectric devices for position control, and capacitive force detection were used to measure the force between a metallic sphere and plate with high accuracy, thereby confirming an attractive force proportional to $1/z^3$. This experiment has been followed by a number of experiments, which have profited by recent developments in nanotechnology (for an overview, see Refs. [44,45]). By attaching a microsphere to the cantilever of an atomic force microscope (playing the role of the spring) and monitoring the dispersion-force induced bending of the cantilever via deflection of an optical beam, the force between the sphere and a nearby surface was measured to obtain very accurate results for various metals [46,47,48,49,50] and/or dielectrics [51,52], including the influence of finite conductivity [46,47,49] as well as surface roughness [48,50]. It was further demonstrated that one-dimensional periodic surface corrugations can lead to a sinusoidally varying tangential force in addition to the attractive normal Casimir force [50,53,54]. A similar experimental setup was used to measure the force between two dielectric cylinders [55] or spheres [56]. Dispersion forces have also been measured by means of a micromachined torsion-balance scheme, where a small plate suspended by two thin rods rotates in response to the Casimir force exerted by a nearby microsphere, and this tilting is monitored by capacitive measurements. The scheme was used to study the force between dissimilar metals [57,58] and to demonstrate its dependence on the thickness of the interacting objects [59,60]. Changing the objects' reflectivity in the visible region by means of hydrogen deposition was found to have no observable influence on the force [60,61], indicating that it should depend on the frequency-dependent body properties in some integral form.

Dispersion forces can also be measured in a dynamical setup, based on the idea that any interaction will affect the relative motion of two objects. In the first experimental realization of this idea, a spherical lens was mounted on a loud speaker and periodically driven, thereby inducing—by means of the Casimir force—a similar motion of a nearby plate mounted on a microphone [62,63]. Detection of the amplitude of the induced oscillations led to accurate force measurements. This idea has been applied in modern experiments to infer the Casimir force from the periodic motion of an object, such as a microsphere oscillating at the tip of an atomic force microscope cantilever while interacting with a surface [64,65], or an oscillating micromachined torsion balance interacting with a rigidly mounted sphere [57,58,66,67]. Dynamical measurements of this kind can also provide high-precision results for atom–body dispersion interactions, which was demonstrated by observing the change of the oscillatory motion of a single excited ion trapped in a standing electromagnetic wave [68], or of cold gases of (ground-state) atoms confined in a magnetic trap [69] or an optical lattice [70], induced by their dispersion interaction with a nearby surface. In the latter experiment, a temperature dependence of dispersion forces was observed.
Controlled dynamical measurements of dispersion forces on atoms have only become feasible recently due to the availability of efficient techniques to cool and trap single atoms. In the early experiments, scattering techniques were employed, which are of course much simpler to implement. Atom–atom interactions have been observed by scattering a beam of ground-state atoms with known narrow velocity profile off a second beam of atoms with thermal velocity distribution \([71,72,73]\) or a stationary target gas \([74,75,76,77]\), where an attractive \(1/z^7\) force was found. Scattering techniques have also been employed to probe the interactions of atoms with anisotropic molecules \([78,79,80]\) and even the interaction of excited atoms with ground-state atoms \([81]\), where in the latter case a strong enhancement of the force was observed. Evidence of atom–body forces was first found by observing the deflection of a beam of ground-state atoms or molecules passing near the surface of a metallic or dielectric cylinder, the results suggesting an attractive \(1/z^4\) force \([82,83,84,85]\). \(^5\) In a similar scheme, the deflection of atoms passing between two metallic plates was monitored by observing the atom flux losses due to the sticking of atoms to the plates. In doing so, a strong enhancement of the force on excited atoms was observed \([86]\). It was further found \([87,88]\) that the distance dependence of the ground-state force changes from a \(1/z^4\) power law for small atom–surface separations (nonretarded regime) to the more rapidly decreasing \(1/z^5\) power law as soon as the separations exceed the relevant transition wavelengths of the atoms and the bodies (retarded regime \(^6\)).

It has turned out that introducing a controllable compensating force is also useful in the context of atom-scattering experiments; this is the central idea of the evanescent-wave mirror: A laser beam is incident on the surface of a dielectric from the inside at a sufficiently shallow angle, such that total reflection leads to an exponentially decaying electric field at its exterior. An atom placed in the vicinity of the body will interact with this evanescent field, leading to an optical potential. If the laser frequency is larger than the relevant atomic transition frequency (blue detuning), then this potential is repulsive; thus creating the required compensating force, which can be controlled by varying the laser frequency and intensity. In this way, dispersion forces on ground-state atoms can be measured by monitoring the reflection of the atoms incident on evanescent-wave mirrors \([89,90,91]\). Alternatively, compensating forces can be provided by the magnetic fields created by magnetic films, the strength being controlled by varying the film thickness \([92]\).

Effects due to the wave nature of the atomic motion become relevant for small values of the (center-of-mass) momentum, such that the atomic de Broglie

\(^5\) In the experiments, the minimum atom–surface separation was so small that to a good approximation, the cylinder surfaces can be regarded as planar.

\(^6\) Note that the abovementioned measurements of Casimir forces between macroscopic bodies typically operate in the retarded regime.
wavelength becomes sufficiently large. In this case quantum reflection of an atom from the potential associated with the atom-body force may occur [93]. Quantum reflection of ground-state [94,95,96,97] or excited atoms [98,99] incident on the surface of dielectric bodies was observed in various experiments, where a detailed measurement of the atom–surface dispersion potential was achieved by recording the reflectivities at different normal velocities. Another prominent wave phenomenon that can be exploited for the measurement of atom–body potentials is the diffraction of an atom wave incident on a transmission grating forming a periodic array of parallel slits. When passing the slits (which may be regarded as being small planar cavities), the atomic matter wave acquires a phase shift due to the dispersion potential, which affects the interference pattern forming behind the slits. By comparing the experimental observations with theoretical simulations, the nonretarded interaction of ground-state [100,101,102,103] as well as excited atoms [104,105,106] with dielectrics has been measured.

Spectroscopic measurements provide a powerful indirect method for studying atom–body dispersion interactions. Here, the fact is exploited that the dispersion potential of an atom can be identified with the position-dependent shift of the respective atomic energy level [107]. The resulting shifts of the atomic transition frequencies can be observed by spectroscopic means. As the shifts are usually much more noticeable for excited levels, this approach yields good estimates of the dispersion potentials of atoms in excited energy eigenstates. This was demonstrated in experiments measuring dispersion potentials of atoms inside planar [108,109,110] and spherical metallic cavities [111,112] or near a dielectric half space [113,114], and of an ion near a metal plate [115]. In this context, selective reflection spectroscopy of atomic gases has proven to be a particularly powerful method [116]. It is based on the fact that the reflection of a laser beam incident on a gas cell is modified due to the laser-induced polarization of the gas atoms, which in turn is strongly influenced by the dispersion interaction of the atoms with the walls of the cell. By comparing measured reflectivity spectra with theoretically computed ones, very accurate information on the nonretarded dispersion interaction of atoms with dielectric plates [117,118,119,120,121,122] was obtained, including the potentials of atoms in very short-lived excited energy eigenstates, which are difficult to study by scattering methods. Note that the dispersion interaction with metallic plates is much more difficult to observe via selective reflection spectroscopy [123]. As a major achievement, the method has shown that the dispersion forces on excited atoms can be repulsive [124,125].
1.3 Applications

Taking advantage of the substantially improved sensitivity of dispersion-force measurements, comparison of the experimental results with theoretical predictions can nowadays even be used to place constraints on other short-scale interactions of fundamental interest, such as non-standard gravitational forces [44,58,69,126,127,128,129]. In addition, dispersion forces have become of increasing importance in applied science such as nanotechnology and related fields. While providing a powerful tool for surface control, e.g., in near-field scanning microscopy [130,131], they can also be a disturbing factor whose influence will become more and more pronounced with proceeding miniaturization. In particular, they can lead to an undesired and permanent sticking of (small) objects to surfaces [132,133,134]. A similarly disturbing effect is observed when atom traps are operated near surfaces, where dispersion forces can diminish the depths of magneto-optical traps, thereby imposing limits upon the near-surface operation of such traps [135,136]. Traps that are based on evanescent waves [137,138,139,140,141] necessarily operate in the near-surface regime so that dispersion forces automatically come into play. The influence of dispersion forces also needs to be taken into account when constructing evanescent-wave based elements for atom guiding [142,143,144,145,146].

Dispersion forces are indispensable in atom optics [147], where mirrors and beam splitters for atomic matter waves have been constructed based on the dispersion interactions of atoms with flat surfaces and transmission gratings, respectively. Transmission gratings can be used to realize Mach–Zehnder-type interferometers for atoms [102]. Flat quantum reflective mirrors provide a focusing mechanism when dispersion and gravitational forces are combined with in an appropriate way [148]. In addition, by locally enhancing the reflectivity of the mirrors via a Fresnel reflection structure [149], reflection holograms for atomic matter waves can be realized [150]. The efficiency of atomic mirrors can also be enhanced by using evanescent-wave mirrors, which can even operate quantum-state selectively [151]. As recently reported, the quantum reflection of ultracold gases at dielectric surfaces gives rise to interesting phenomena, such as the excitation of solitons and vortex structures [152].

Further impact on the application of dispersion forces has been given by the recent proposal [153] and subsequent fabrication [154] of materials with tailored magnetodielectric properties, also known as metamaterials. Metamaterials displaying simultaneous negative permittivity and permeability in some frequency range allow for the existence of travelling electromagnetic waves whose electric-field, magnetic-field, and wave vector form a left-handed triad [160].

---

7 For the current state-of-art of metamaterial fabrication, see, e.g., Refs. [155,156,157,158,159].
8 For this reason materials with these properties are commonly referred to as left-
leading to a number of unusual effects. It is yet an open question whether left-handed properties can lead to interesting phenomena in the context of dispersion forces and to what extent metamaterials can be exploited to tailor the shape and sign of these forces. An interesting behavior of dispersion forces may also occur in conjunction with soft-magnetic alloys, such as permalloy or mumetal [161,162]. After heating and rapid cooling (a process called annealing), these materials are in a state of extremely high permeability; values of more than $5 \times 10^4$ have been reported for mumetal [163].

1.4 Theoretical approaches

As already mentioned, dispersion forces arise from quantum zero-point fluctuations, namely the fluctuating charge and current distributions of the interacting objects and the vacuum fluctuations of the (transverse) electromagnetic field. If the separation of the objects is smaller than the wavelengths of the relevant field fluctuations, then the latter can be disregarded, allowing for a simplified treatment of dispersion forces. In this nonretarded regime, dispersion forces are dominated by the Coulomb interaction of fluctuating charge densities. Within a leading-order multipole expansion, this interaction may further be approximated by a dipole–dipole interaction. This approach was first used by London, who employed second-order perturbation theory to derive an attractive $1/z^7$ force between two ground-state atoms [164]. The idea of deriving dispersion forces from dipole–dipole interactions by means of perturbation theory was later applied to calculate three- [165,166,167,168,169,170,171], four- [172], or $N$-atom interaction potentials [173,174,175,176]. Lennard-Jones showed [177] that the interaction of an atom with a perfectly conducting plate can be treated on an equal footing, by using the image-charge method. Considering the dipole–dipole interaction of the atom with its own image in the plate (instead of a second atom) within first-order perturbation theory, he found an attractive $1/z^4$ force. The influence of fluctuating magnetic dipoles [178,179,180], electric quadrupoles [181] or higher multipoles [182,183] as well as permanent electric [164,168,184,185] and magnetic dipoles [184] on the atom–atom interaction has also been discussed. In this way, it was found that the force between a magnetizable and a polarizable one is repulsive and proportional to $1/z^5$, in contrast to the attractive $1/z^7$ force between two polarizable atoms. Furthermore, studying the interaction of atoms prepared in excited energy eigenstates showed that the contributions to the force which arise from real, resonant transitions can be attractive or repulsive [168,179,184]. (For further reading regarding the atom–atom interaction, refer to Refs. [186,187,188]). Similar extensions have been accomplished regarding the interaction of atoms with (planar) bodies. Quadrupole [189] and higher-handed materials.
order multipole atomic moments [190,191,192] were included in the interaction of ground-state atoms with perfectly conducting plates, and extensions of the image-charge method to the interaction of ground-state [193,194] or atoms in excited energy eigenstates [195] with planar dielectric bodies were given.

The method can be further improved by describing the atom and the body on an equal footing in terms of their charge densities and expressing the resulting interaction potential in terms of electrostatic linear response functions of the two systems. This was first demonstrated for a ground-state atom interacting with a realistic metallic half space exhibiting nonlocal properties [196]. The approach was demonstrated to lead to a finite value of the interaction potential in the limit $z \to 0$ [190,200,201,202,203]. For sufficiently large values of $z$, the force on an atom in front of a half space can be given by an asymptotic power series in $1/z$ [196,206,207,208,209], where the leading-order $1/z^4$ term, which is given in terms of the atomic dipole polarizability and the local dielectric permittivity of the half space, reduces to the perfect conductor result in the limit of infinite permittivity. Next-order corrections are due to the atomic quadrupole polarizability on the one hand [203] and the leading-order nonlocal response on the other hand [196]. The response-function expression for the interaction of ground-state objects with a half space has been used to calculate the forces on an ion [210] or permanently polarized atom [211,212] in front of a metallic half space, an anisotropic molecule in front of a dielectric half space [213] as well as the interaction of two atoms in front of a metallic [214,215] or dielectric half space [216]. Extensions include the interaction of an atom in an excited energy eigenstate with a metallic [217] or birefringent dielectric half space [218], nonperturbative effects [219] or effects due to a constant external magnetic field [220], and the interaction of single ground-state atoms/molecules with bodies of various shapes, where perfectly conducting [221], metallic [222,223], or dielectric spheres [221], metallic [224,225] or dielectric cylinders [226], and perfectly conducting planar [227] or metallic spherical cavities [228,229] have been considered.

The interaction of two macroscopic bodies was first treated by a pairwise summation over the microscopic London forces between the atoms constituting the bodies [230,231], yielding an attractive $1/z^3$ force between two semi-infinite half spaces [230,232]. Though applicable to bodies of various shapes (cf. also Refs. [200,233]), the method could only yield approximate results due to the restriction to two-atom interactions. By modeling the body atoms by harmonic oscillators, the interaction energy of the bodies could be shown to be a sum

---

9 In contrast to the quantities appearing in earlier attempts to treat metals in a more realistic way [197,198,199], the two response functions are directly accessible to measurements.

10 For the dispersion interaction between two dielectric half spaces, this was shown in Refs. [204,205].
of all possible many-atom interaction potentials [230,232]. Applications to the interaction of two half spaces [175] and two spheres [234] were studied. Microscopic calculations of the dispersion interaction between bodies were soon realized to be very cumbersome, in particular for more involved geometries. In an alternative approach based on macroscopic electrostatics, the interaction energy can be derived from the eigenmodes of the electrostatic Coulomb potential, which are subject to the boundary conditions imposed by the surfaces of discontinuity [235,236] (for an overview, cf. Ref. [45]). The method was used to calculate Casimir forces between dielectric spheres [236], dielectric spherical cavities [237], metallic half spaces exhibiting nonlocal properties [208], rough dielectric half spaces [238,239], and electrolytic half spaces separated by a dielectric [240].

Even though electrostatic methods have been developed into a sophisticated theory covering various aspects of dispersion forces, they can only render approximate results valid in the nonretarded limit, where the object separations are sufficiently small so that the influence of the transverse electromagnetic field can be disregarded. This was first demonstrated by Casimir and Polder [107,241]. Using a normal-mode expansion of the quantized electromagnetic field inside a planar cavity bounded by perfectly conducting plates, they showed that the force between the plates can be derived from the separation-dependent total electromagnetic energy. In a similar way, they obtained the force on an atom near one of such plates and the force between two atoms in free space from the ground-state energy of the respective system in leading-order perturbation theory. The difficulty that the energies hence obtained were divergent was overcome by subtracting the respective diverging energies corresponding to infinite object separation, leading to finite, position-dependent results. Casimir and Polder had thus developed a unified theory to describe dispersion interactions over a large range of distances. In particular, they recovered the results of the nonretarded limit and found that in the retarded limit the atom–atom, atom–plate, and plate–plate forces remain attractive, but decrease more rapidly as $1/z^8$, $1/z^5$, and $1/z^4$, respectively.

Normal-mode techniques have since widely been used to study dispersion interactions. The two-atom interaction has been confirmed in various ways [242,243,244,245,246,247,248,249,250,251,252,253,254,255,256], inter alia by basing the calculations on the multipolar-coupling scheme [242,244,253] in place of the minimal-coupling scheme originally used by Casimir and Polder, and relativistic corrections have been considered [257]. Extensions include the interaction of three [246,254,258,259,260,261] or more atoms [262,263], the influence of higher-order multipole moments [264] and permanent dipole moments [265] on the two-atom force, the interaction between anisotropically polarizable atoms [266], and that between a polarizable and a magnetizable atom [267,268,269,270,271,272,273] (for an overview, cf. Ref. [274]). In particular, it was found that in the retarded limit the force between a polarizable and a mag-
netizable atom is repulsive as in the nonretarded limit, but follows the same $1/z^8$ power law as that between two polarizable atoms. Furthermore, the interaction of atoms in excited energy eigenstates [275,276,277,278,279,280,281] and the influence of external conditions such as finite temperature [272,282,283,284,285], applied electromagnetic fields [284], or additional bodies [266,286,287,288] on the atom–atom interaction have been studied. In particular, when the interatomic separation exceeds the thermal wavelength, the force decreases more slowly ($\sim 1/z^7$) than in the zero-temperature limit. Similarly, the Casimir–Polder result for the atom–plate interaction has been confirmed [246,247,248,249,251,268,289], atoms that carry permanent electric dipole moments [290] or are magnetizable [291] have been considered, and the influence of finite temperature [283,292] as well as force fluctuations [293] has been studied. In close analogy to the atom–atom interaction, it was found that the interaction between a magnetizable atom and a perfectly conducting plate is repulsive, and that the force decreases more slowly ($\sim 1/z^4$) than in the zero-temperature limit as soon as the atom–plate separation exceeds the thermal wavelength. In contrast to the atom–atom interaction, the atom–plate potential for an atom in an excited energy eigenstate was found to show an oscillatory behavior in the retarded limit [250,286,294,295], thereby making the effect of the transverse electromagnetic field more explicit. In addition, atoms interacting with bodies of different shapes and materials have been considered, such as perfectly conducting planar [290,296,297,298,299,300] or cylindrical cavities [301,302], metallic [303], dielectric [304,305,306,307], or even magnetodielectric half spaces [308], or dielectric planar [309,310] or spherical cavities [311].

Needless to say that the pioneering work of Casimir and Polder on dispersion forces has also stimulated further studies of the problem of body–body interactions (for reviews see Refs. [44,312]). Apart from confirming the original results [313,314], normal-mode techniques have been employed to include effects that arise from finite temperatures [315], the presence of a dielectric medium between the plates [316], or even virtual electron–positron pairs [317,318] (where the latter was found to be negligibly small). As in the case of atom–body interactions, various other geometries and materials have been considered, such as two dielectric [319,320,321,322,323], locally [324,325,326] or nonlocally responding metallic half spaces [327], two plates that are polarizable and magnetizable [328,329,330,331,332,333,334], the faces of a perfectly conducting rectangular cavity [335,336], two dielectric multilayer stacks [337], two dielectric spheres [338], a perfectly conducting plate and a small dielectric sphere [339], or a sphere and a surrounding spherical cavity [340]. The results qualitatively resemble the findings for the atom–atom and atom–body interactions. In particular, retardation was found to lead to a stronger asymptotic decrease of the forces, which is softened due to thermal effects as soon as the separations exceed the thermal wavelengths; and the force between a polarizable object and a magnetizable object was found to be repulsive. Perhaps a more surprising result is the fact that two birefringent plates may exert a
nonvanishing dispersion torque on each other [341,342]. Moreover, the problem of Casimir energies of single bodies\textsuperscript{11} has been addressed, motivated by a conjecture made by Casimir [343], according to which an attractive Casimir energy of an electron (modeled as a small perfectly conducting sphere) should be able to counterbalance the repulsive self-energy of the electron charge and thus explain its stability.\textsuperscript{12} However, the energy of a perfectly conducting sphere was found to be repulsive [344,345], with similar findings for a weakly dielectric sphere [346,347,348,349]. On the contrary, the Casimir energy of a weakly dielectric cylinder was found to be attractive, in agreement with expectations [347,350]. The physical significance of Casimir energies of single objects is yet unclear; in particular it was shown by pairwise summation over microscopic dispersion energies that dispersion energies of macroscopic objects are in fact dominated by the always attractive volume and surface energies, and may hence never be observed [351]. In standard calculations, of Casimir energies, these volume and surface energies are either not considered from the very beginning or discarded during regularization procedures [349].

Normal-mode techniques have proved to be a powerful tool for studying dispersion forces (cf. also Refs. [3,352]). Nevertheless, some principal limitations of the approach have become apparent recently, in particular in view of the new challenges in connection with recent improvements on the experimental side. So, normal-mode calculations can become extremely cumbersome when applied to object geometries relevant to practice, or when a realistic description of the electromagnetic properties of the interacting objects is required. The limitations are also illustrated by the controversy regarding the low-temperature behavior of dispersion forces on bodies (for a recent account of the debate, see Ref. [353] and references therein). The answer to this question requires detailed knowledge of the complicated interplay of positional, thermal, and spectral factors. To see this, one has to bear in mind that, in general, a large range of frequencies contributes to the forces, where the relative influence of different frequency intervals is determined by the object–object separation, temperature, and the frequency dependence of the object properties. As a consequence, approximations such as long-/short-range, high-/low-temperature or perfect-reflectivity limits become intrinsically intertwined. A typical material property relevant to dispersion forces is the permittivity, which is a complex function of frequency, with the real and the imaginary part being responsible for dispersion and absorption, respectively. In particular, absorption, which introduces additional noise into a system, inhibits the application of normal-mode expansion on a macroscopic level. This point was first taken into account by Lifshitz

\textsuperscript{11}The Casimir energy of a single body can be defined as the geometry-dependent part of the total electromagnetic energy, where the notion geometry-dependent part is subject to ambiguities, cf. the discussion below. For further reading on the Casimir energy of a single body, cf. Ref. [312].

\textsuperscript{12}For a further discussion of this idea, cf. Ref. [3].
in his calculation of the dispersion force between two dielectric half spaces at finite temperature [354,355], where he derived the force from the average of the stress tensor of the fluctuating electromagnetic field at the surfaces of the half spaces, with the source of the field being the fluctuating noise current within the dielectric matter. The required average was obtained by noting that the current fluctuations are linked to the imaginary part of the permittivity via the fluctuation-dissipation theorem. In this way, Lifshitz could express the force in terms of the exact dielectric response of the half spaces. The Lifshitz theory has been applied and extended by a number of authors (for an overview see Refs. [44,312]), who studied the influence of different frequency ranges [356,357,358,359], effects of finite temperatures [360,361,362,363] and surface roughness [364], and other planar structures such as electrolytic half spaces separated by a dielectric [365], magnetodielectric half spaces [366], metallic plates of finite thickness [367], metallic half spaces exhibiting nonlocal properties [362,368], and even dielectric multilayer systems [369] (for further reading, cf., e.g., Ref. [233]). A typical approximation for treating small deviations from planar structures (like a sphere that is sufficiently close by a plate [325]) is the proximity force approximation, where it is assumed that the interaction of two objects with gently curved surfaces can be obtained by simply integrating the energy per unit area along the surfaces [370].

While the debate regarding the temperature dependence of the force between real metallic half spaces still seems unsettled, general consensus is reached that inclusion or neglect of material absorption (i.e., use of a Drude-type or a plasma-type permittivity) leads to the disagreeing results [353]. It is worth noting that the forces in a planar structure can be reexpressed in terms of (frequency-dependent) reflection coefficients directly accessible from experiments. This formulation of the theory has been applied to metallic [372,373] and dielectric half spaces [374], metallic half spaces with nonlocal properties [375], dielectric multilayer stacks [376], and, in some approximation, to rough metalic half spaces [377,378,379,380], where the surface roughness gives rise to a tangential force component [381].

Lifshitz’s idea of expressing dispersion forces in terms of response functions is of course not restricted to planar systems, but can be extended to arbitrary geometries. This can be achieved by expressing the results obtained by normal-mode expansion in terms of the Green tensor of the (classical) electromagnetic field [382,383,384]. Alternatively, the Green tensor, which contains all the necessary information on the shape and the relevant electromagnetic properties of the objects, can be introduced by applying path-integral techniques [385,386] or employing the fluctuation-dissipation theorem [387]. The theory has been used to study the force between two perfectly conducting plates [382,388], a perfectly conducting plate and a perfectly permeable plate [384], two dielectric

---

13Recently, validity limits for the proximity force approximation in the case of perfectly conducting objects have been discussed on the basis of numerical calculations [371].
half spaces [323,389], two dielectric plates [387], and, in some approximation, the force between two perfectly conducting spheres [384,388] and between a perfectly conducting sphere and a perfectly conducting plate [388], and the force and the torque between weakly dielectric objects of arbitrary shapes [383]. In particular, it was shown that the force between two mirror-symmetric dielectric objects is always attractive [390]. Casimir energies of a perfectly conducting sphere [382], a dielectric sphere [386], magnetodielectric sphere [391], and a perfectly conducting cylinder [392] have also been studied in this way.

The concept of linear response theory has also been widely used to study dispersion forces on atoms. In particular, it can be shown that the interaction energy between a ground-state atom and the electromagnetic vacuum in leading-order perturbation theory can be expressed in terms of the linear response functions of the two systems, i.e., the atomic polarizability on the one hand, and the Green tensor of the electromagnetic field on the other hand, thus rendering a general expression for the force on an atom in the presence of arbitrary bodies [200,393,394,395,396]. The method, which can easily be extended to thermal fields [397,398,399], also applies to the dispersion interaction of two ground-state atoms in free space [393,397] or in the presence of bodies [216]. However, it cannot directly be applied to atoms in excited energy eigenstates, where it is necessary to again start from the leading-order interaction energy and only express the field contribution in terms of the respective response function [400,401]. Linear response theory has been used to study the dispersion interaction of a single ground-state atom with a multitude of bodies, such as perfectly conducting plates [393,394,396,397], dielectric [394,396,398,402], and magnetodielectric half spaces [403], metallic half spaces exhibiting nonlocal properties [395,404] and/or surface roughness [395,405] or being covered by a thin overlayer [406], perfectly conducting [407] and dielectric spheres [386,408,409,410], dielectric cylinders [408,411,412,413], perfectly conducting or dielectric planar cavities [414] as well as dielectric spherical [415], cylindrical [412], or wedge-shaped cavities [386,410]. Moreover, the force on an atom in an excited energy eigenstate in front of a perfectly conducting [400,401] or dielectric [401] or birefringent dielectric half space [416] has been considered, and the interaction of two ground-state atoms embedded in a dielectric medium [417], placed near a perfectly conducting [418] or dielectric half space [402,419] or inside a perfectly conducting [418,420] or dielectric planar cavity [421] has been studied.

Finally, relations between microscopic and macroscopic dispersion forces have been established whose validity is no longer restricted to the nonretarded limit. Modeling macroscopic bodies by a collection of harmonic-oscillator atoms in-

---

14 Note that the method is the natural extension of the approach based on the electrostatic response function, which is now replaced by the response function for the complete electromagnetic field including its transverse part.
teracting with the electromagnetic field and calculating the total energy of the interacting system, both the the force on a single ground-state atom in the presence of a dielectric half space and the force between two dielectric half spaces were derived from microscopic atom–atom interactions [422], where the former result was later extended beyond the harmonic-oscillator model [423]. A harmonic-oscillator model of atoms, with the atoms being coupled to a heat bath, was used to derive the force between absorbing dielectric half spaces, confirming the result of Lifshitz theory [424]. The microscopic-model calculations show that only in the limit of weakly polarizable bodies, i.e., small values of the susceptibilities, a pairwise sum over two-atom forces is sufficient to obtain the total force, stressing once more the importance of many-atom interactions in the context of body-assisted dispersion forces. Pairwise summation of two-atom interactions can be used to obtain an approximate description of the interaction between intricately shaped objects, e.g., bodies with rough surfaces [425],15 or of atom–body/body–body interactions involving excited atoms and/or bodies [280,281,428]. Conversely, from well-known formulas for the body–body interaction, formulas for the atom–body interaction [354,355,385,386,429,430,431,432,433,434,435] as well as the atom–atom interaction [285,354,355,432,435,436] can be obtained in the limit of the respective susceptibilities being asymptotically small.

As we have seen, various concepts have been developed to describe dispersion forces, which, to some extent, are based on different basic assumptions and hence impose different limitations upon the applicability. The QED concepts based on normal-mode expansion of the quantized electromagnetic field typically suffer from the fact that when macroscopic bodies come into play, these bodies should be regarded as nonabsorbing and hence also nondispersive. To overcome this difficulty, arguments from other theories, such as the fluctuation–dissipation theorem of statistical physics, must be borrowed. On the contrary, the concepts based on linear response theory abandon an explicit field quantization and employ the fluctuation–dissipation theorem from the beginning. However, the applicability of methods that make use of the fluctuation–dissipation theorem by some means or other is limited to equilibrium systems—a disadvantage when dynamical aspects of excited atoms are to be considered. All concepts have in common that macroscopic bodies are typically described in terms of macroscopic electrodynamics, i.e., boundary conditions at surfaces of discontinuity and/or constitutive relations. In this article we therefore follow the formalism of macroscopic QED in media (as developed, e.g., in Refs. [437,438,439]) from the very beginning to give a unified approach to dispersion forces which does not only combine the benefits of normal-mode QED and linear response theory in a natural way but also

15 For bodies with small deviations from the planar geometry, the result of pairwise summation can be improved by introducing a correction factor obtained from Lifshitz theory [426,427].
accentuates the common origin of and intimate relations between the different types of forces and extends the range of application.

The further contents of the article are organized as follows. In Sec. 2 the main features of the quantization of the electromagnetic field in linear, dispersing and absorbing media and the interaction of the medium-assisted field with atoms is outlined, with special emphasis on magnetodielectric media described in terms of spatially varying permittivities and permeabilities which are complex functions of frequency. On this basis, in Sec. 3, very general formulas for the force on a macroscopic body due to its interaction with other macroscopic bodies are presented, which are valid for arbitrarily shaped bodies as all the relevant properties of the bodies are fully expressed in terms of the Green tensor of the associated macroscopic Maxwell equations. Both Casimir stress and Casimir force are introduced, and a very general relation to many-atom van der Waals forces is established. In particular, it is shown that both the force on a single ground-state atom interacting with a body and the force between two ground-state atoms can be obtained as limiting cases of the general formulas. In Sec. 4, forces on individual atoms interacting with the body-assisted electromagnetic field are studied in more detail, with special emphasis on explicitly solving the corresponding quantum mechanical interaction problem. It is demonstrated how the force on one or two ground-state atoms in the presence of magnetodielectric bodies can be calculated by leading-order perturbation theory, the results agreeing with those obtained in Sec. 3. A number of examples is studied, where it is shown that dispersion forces are often given by simple asymptotic power laws in the retarded and nonretarded limits. The force on a single atom initially prepared in an arbitrary excited quantum state is calculated by solving the atom-field dynamics, leading to explicitly time-dependent results. Some concluding are given in Sec. 5.

2 Elements of QED in linear, causal media

It is well known that the properties of the electromagnetic field in media can significantly differ from those observed in free space, and hence, the interaction of the field with atoms can strongly be influenced by the presence of media. In classical electrodynamics, linear media are commonly described in terms of phenomenologically introduced macroscopic electric and magnetic susceptibilities (or permittivities and permeabilities, respectively) available from measurable data. This concept, which can be transferred to quantum electrodynamics, has the benefit of being universally valid, because it uses only very general physical properties, without the need for specific microscopic matter models and involved ab initio calculations.
2.1 The medium-assisted electromagnetic field

The medium-assisted electromagnetic field in the absence of free charges or currents obeys the macroscopic Maxwell equations, which in the Fourier domain read

\[
\nabla \cdot \hat{\mathbf{B}}(\mathbf{r}, \omega) = 0, \\
\n\nabla \times \hat{\mathbf{E}}(\mathbf{r}, \omega) - i\omega \hat{\mathbf{B}}(\mathbf{r}, \omega) = 0, \\
\varepsilon_0 \nabla \cdot \hat{\mathbf{E}}(\mathbf{r}, \omega) = \hat{\rho}_\text{in}(\mathbf{r}, \omega), \\
\kappa_0 \nabla \times \hat{\mathbf{B}}(\mathbf{r}, \omega) + i\omega \varepsilon_0 \hat{\mathbf{E}}(\mathbf{r}, \omega) = \hat{\mathbf{j}}_\text{in}(\mathbf{r}, \omega)
\]

(\kappa_0 = \mu_0^{-1}), where the internal charge and current densities of the magnetodielectric media \(\hat{\rho}_\text{in}(\mathbf{r}, \omega)\) and \(\hat{\mathbf{j}}_\text{in}(\mathbf{r}, \omega)\) are the sources for the electric field \(\hat{\mathbf{E}}(\mathbf{r}, \omega)\) and the induction field \(\hat{\mathbf{B}}(\mathbf{r}, \omega)\). Note that the picture-independent Fourier components \(\hat{\mathcal{O}}(\mathbf{r}, \omega)\) of an operator field \(\hat{\mathcal{O}}(\mathbf{r})\) are defined according to

\[
\hat{\mathcal{O}}(\mathbf{r}) = \int_0^\infty d\omega \hat{\mathcal{O}}(\mathbf{r}, \omega) + \text{H.c.}
\]

so that \(\hat{\mathcal{O}}(\mathbf{r}, \omega, t) = e^{-i\omega(t-t')}\hat{\mathcal{O}}(\mathbf{r}, \omega, t')\) in the Heisenberg picture. Since the internal charge and current densities are subject to the continuity equation

\[
-i\omega \hat{\rho}_\text{in}(\mathbf{r}, \omega) + \nabla \cdot \hat{\mathbf{j}}_\text{in}(\mathbf{r}, \omega) = 0,
\]

they may be related to polarization and magnetization fields \(\hat{\mathbf{P}}(\mathbf{r}, \omega)\) and \(\hat{\mathbf{M}}(\mathbf{r}, \omega)\) as follows:

\[
\hat{\rho}_\text{in}(\mathbf{r}, \omega) = -\nabla \cdot \hat{\mathbf{P}}(\mathbf{r}, \omega), \\
\hat{\mathbf{j}}_\text{in}(\mathbf{r}, \omega) = -i\omega \hat{\mathbf{P}}(\mathbf{r}, \omega) + \nabla \times \hat{\mathbf{M}}(\mathbf{r}, \omega).
\]

Upon introducing the displacement field

\[
\hat{\mathbf{D}}(\mathbf{r}, \omega) = \varepsilon_0 \hat{\mathbf{E}}(\mathbf{r}, \omega) + \hat{\mathbf{P}}(\mathbf{r}, \omega)
\]

and the magnetic field

\[
\hat{\mathbf{H}}(\mathbf{r}, \omega) = \kappa_0 \hat{\mathbf{B}}(\mathbf{r}, \omega) - \hat{\mathbf{M}}(\mathbf{r}, \omega),
\]

the inhomogeneous Maxwell equations (3) and (4) can hence be written in the familiar equivalent form

\[
\nabla \cdot \hat{\mathbf{D}}(\mathbf{r}, \omega) = 0, \\
\n\nabla \times \hat{\mathbf{H}}(\mathbf{r}, \omega) + i\omega \hat{\mathbf{D}}(\mathbf{r}, \omega) = 0,
\]
where the source terms associated with the internal charge and current densities are now contained in the displacement and magnetic fields.

In particular in the case of linearly and locally responding magnetodielectric media, Eqs. (9) and (10) take the form

\[ \hat{\mathbf{P}}(\mathbf{r}, \omega) = \varepsilon_0[\varepsilon(\mathbf{r}, \omega) - 1]\hat{\mathbf{E}}(\mathbf{r}, \omega) + \hat{\mathbf{P}}_N(\mathbf{r}, \omega), \quad (13) \]

\[ \mathbf{M}(\mathbf{r}, \omega) = \kappa_0[1 - \kappa(\mathbf{r}, \omega)]\hat{\mathbf{B}}(\mathbf{r}, \omega) + \mathbf{M}_N(\mathbf{r}, \omega) \quad (14) \]

\[ [\kappa(\mathbf{r}, \omega) = \mu^{-1}(\mathbf{r}, \omega)], \text{ with } \varepsilon(\mathbf{r}, \omega) \text{ and } \mu(\mathbf{r}, \omega) \text{ being the (relative) electric permittivity and magnetic permeability of the media, respectively. Causality implies that } \varepsilon(\mathbf{r}, \omega) \text{ and } \mu(\mathbf{r}, \omega), \text{ which vary with space in general, are complex-valued functions of } \omega, \text{ with the Kramers–Kronig relations being satisfied [440]. According to the fluctuation–dissipation theorem, } \hat{\mathbf{P}}_N(\mathbf{r}, \omega) \text{ and } \mathbf{M}_N(\mathbf{r}, \omega) \text{ are the (linear) noise polarization and magnetization, respectively, associated with the (linear) absorption described by the imaginary parts of } \varepsilon(\mathbf{r}, \omega) [\text{Im}\varepsilon(\mathbf{r}, \omega) > 0] \text{ and } \mu(\mathbf{r}, \omega) [\text{Im}\mu(\mathbf{r}, \omega) > 0]. \text{ For simplicity, in Eqs. (13) and (14) the material is assumed to be isotropic.}^{16} \]

Substituting Eqs. (9), (10), (13), and (14) into Eq. (12) and making use of Eq. (2), one can verify that the electric field obeys the inhomogeneous Helmholtz equation

\[ \left[ \nabla \times \kappa(\mathbf{r}, \omega) \nabla \times - \frac{\omega^2}{c^2} \varepsilon(\mathbf{r}, \omega) \right] \hat{\mathbf{E}}(\mathbf{r}, \omega) = i\omega \mu_0 \hat{\mathbf{j}}_N(\mathbf{r}, \omega), \quad (15) \]

where the source term is determined by the noise current density

\[ \hat{\mathbf{j}}_N(\mathbf{r}, \omega) = -i\omega \hat{\mathbf{P}}_N(\mathbf{r}, \omega) + \nabla \times \mathbf{M}_N(\mathbf{r}, \omega). \quad (16) \]

Note that noise current density and noise charge density

\[ \hat{\mathbf{P}}_N(\mathbf{r}, \omega) = -\nabla \cdot \hat{\mathbf{P}}_N(\mathbf{r}, \omega) \quad (17) \]

fulfills the continuity equation,

\[ -i\omega \hat{\mathbf{P}}_N(\mathbf{r}, \omega) + \nabla \cdot \hat{\mathbf{j}}_N(\mathbf{r}, \omega) = 0 \quad (18) \]

[recall Eqs. (6)–(8)]. The solution to Eq. (15) can be given in the form

\[ \hat{\mathbf{E}}(\mathbf{r}, \omega) = i\omega \mu_0 \int d^3r' \mathbf{G}(\mathbf{r}, \mathbf{r}', \omega) \cdot \hat{\mathbf{j}}_N(\mathbf{r}', \omega), \quad (19) \]

\[ ^{16} \text{The theory can be extended to arbitrary media, by starting from the general linear response relation between the current density and the electric field. Formulas in this article which do not explicitly refer to material properties (but solely via the Green tensor) are valid for arbitrary linear media.} \]
which, according to Eq. (2), implies that

$$\bar{B}(r, \omega) = \mu_0 \int d^3 r' \nabla \times G(r, r', \omega) \cdot \hat{j}_N(r', \omega).$$

(20)

Here, $G(r, r', \omega)$ is the (classical) Green tensor, which is defined by the equation

$$\left[ \nabla \times \kappa(r, \omega) \nabla - \frac{\omega^2}{c^2} \varepsilon(r, \omega) \right] G(r, r', \omega) = \delta(r - r')I$$

(21)

($I$: unit tensor) together with the boundary condition

$$G(r, r', \omega) \to 0 \quad \text{for} \quad |r - r'| \to \infty.$$  

(22)

It should be pointed out that the Green tensor is uniquely defined by Eqs. (21) and (22) provided that the strict inequalities Im$\varepsilon(r, \omega) > 0$ and Im$\mu(r, \omega) > 0$ hold. Note that it is a holomorphic function of $\omega$ in the upper complex half plane and and has the following useful properties ($A^T_{ij} = A_{ji}$):

$$G^*(r, r', \omega) = G(r, r', -\omega^*),$$

(23)

$$G(r, r', \omega) = G^T(r', r, \omega),$$

(24)

$$\int d^3 s \left\{ -\text{Im} \kappa(s, \omega) [\nabla_s \times G(s, r, \omega)]^T \cdot [\nabla_s \times G^*(s, r', \omega)] 
+ \frac{\omega^2}{c^2} \text{Im} \varepsilon(s, \omega) G(r, s, \omega) \cdot G^*(s, r', \omega) \right\} = \text{Im} G(r, r', \omega).$$

(25)

Noise polarization and magnetization, and hence, the noise current density can be related to dynamical variables of the combined system (i.e., the system which consists of the electromagnetic field and the magnetodielectric matter, including the dissipate system responsible for absorption), as follows [437,438]:

$$\bar{P}_N(r, \omega) = i \sqrt{\frac{\hbar \varepsilon_0}{\pi}} \text{Im} \varepsilon(r, \omega) \hat{f}_e(r, \omega),$$

(26)

$$\bar{M}_N(r, \omega) = \sqrt{\frac{\hbar \kappa_0}{\pi}} \text{Im} \kappa(r, \omega) \hat{f}_m(r, \omega) = \sqrt{\frac{\hbar}{\pi \mu_0 |\mu(r, \omega)|^2}} \text{Im} \mu(r, \omega) \hat{f}_m(r, \omega),$$

(27)

where the dynamical variables $\hat{f}_e(r, \omega)$ and $\hat{f}_m(r, \omega)$ ($\lambda \in \{e, m\}$) are attributed to collective excitations of the combined system—in agreement with quantization schemes on the basis of microscopic harmonic-oscillator models of dispersing and absorbing dielectric matter [441,442]—and obey the Bosonic commutation relations

$$[\hat{f}_{\lambda i}(r, \omega), \hat{f}^\dagger_{\lambda' i'}(r', \omega')] = \delta_{\lambda \lambda'} \delta_{ii'} (r - r') \delta(\omega - \omega'),$$

(28)

$$[\hat{f}_{\lambda i}(r, \omega), \hat{f}_{\lambda' i'}(r', \omega')] = 0.$$  

(29)
By substituting Eqs. (26) and (27) into Eq. (19), on recalling Eq. (16), we may express the medium-assisted electric field in terms of the dynamical variables \( \hat{f}_\lambda(r, \omega) \) and \( \hat{f}_\lambda'(r, \omega) \) to obtain

\[
\hat{E}(r, \omega) = \sum_{\lambda=e,m} \int d^3r' \, G_\lambda(r, r', \omega) \cdot \hat{f}_\lambda(r', \omega),
\]

where

\[
G_e(r, r', \omega) = i \frac{\omega^2}{c^2} \sqrt{\frac{\hbar}{\pi \varepsilon_0}} \frac{\text{Im} \varepsilon(r', \omega)}{\text{Im} \varepsilon(\omega)} G(r, r', \omega),
\]

\[
G_m(r, r', \omega) = i \frac{\omega}{c} \sqrt{-\frac{\hbar}{\pi \varepsilon_0}} \frac{\text{Im} \kappa(r', \omega)}{\text{Im} \kappa(\omega)} [\nabla_{r'} \times G(r', \omega)]^T,
\]

so that, according to Eq. (5),

\[
\hat{E}(r) = \int_0^\infty d\omega \, \hat{E}(r, \omega) + \text{H.c.}
\]

\[
= \sum_{\lambda=e,m} \int_0^\infty d\omega \, \int d^3r' \, G_\lambda(r, r', \omega) \cdot \hat{f}_\lambda(r', \omega) + \text{H.c.}
\]

Note that the relation (25) can be written in the more compact form

\[
\sum_{\lambda=e,m} \int d^3s \, G_\lambda(r, s, \omega) \cdot G_\lambda^*(r', s, \omega) = \frac{\hbar \mu_0}{\pi} \omega^2 \text{Im} G(r, r', \omega). 
\]

By starting from Eq. (30) and making use of the Maxwell equations (2) and (12) together with Eqs. (9), (10), (13), (14), (26), and (27), the other electromagnetic-field quantities such as \( \hat{B}(r), \hat{D}(r), \) and \( \hat{H}(r) \) can be expressed in terms of the dynamical variables \( \hat{f}_\lambda(r, \omega) \) and \( \hat{f}_\lambda'(r, \omega) \) in a straightforward way. In particular, one derives

\[
\hat{B}(r, \omega) = \frac{1}{i \omega} \sum_{\lambda=e,m} \int d^3r' \, \nabla \times G_\lambda(r, r', \omega) \cdot \hat{f}_\lambda(r', \omega),
\]

and hence,

\[
\hat{B}(r) = \int_0^\infty d\omega \, \hat{B}(r, \omega) + \text{H.c.}
\]

\[
= \sum_{\lambda=e,m} \int_0^\infty \frac{d\omega}{i \omega} \int d^3r' \, \nabla \times G_\lambda(r, r', \omega) \cdot \hat{f}_\lambda(r', \omega) + \text{H.c.}
\]

In view of the treatment of the interaction of the medium-assisted electromagnetic field with atoms, it may be expedient to express the electric and
induction fields in terms of potentials,

\[
\hat{E}(\mathbf{r}) = -\nabla \hat{\phi}(\mathbf{r}) - \dot{\mathbf{A}}(\mathbf{r}),
\]
\[
\hat{B}(\mathbf{r}) = \nabla \times \dot{\mathbf{A}}(\mathbf{r}).
\]  

(37)  

(38)

In Coulomb gauge, \(\nabla \cdot \dot{\mathbf{A}}(\mathbf{r}) = 0\), the first and second terms on the r.h.s. of Eq. (37) are equal to the longitudinal (\(||\)) and transverse (\(\perp\)) parts of the electric field, respectively. From Eq. (33) it then follows that \(\nabla \hat{\phi}(\mathbf{r})\) and \(\dot{\mathbf{A}}(\mathbf{r})\) can be expressed in terms of the dynamical variables \(\hat{f}_\lambda(r, \omega)\) and \(\hat{f}^\dagger_\lambda(r, \omega)\) as

\[
\nabla \hat{\phi}(\mathbf{r}) = -\hat{E}|| (\mathbf{r}) = -\sum_{\lambda=e,m} \int_0^\infty \frac{d\omega}{\omega} \int d^3r' \parallel G_{\lambda}(\mathbf{r}, \mathbf{r'}, \omega) \cdot \hat{f}_\lambda(\mathbf{r'}, \omega) + \text{H.c.},
\]
\[
\dot{\mathbf{A}}(\mathbf{r}) = \sum_{\lambda=e,m} \int_0^\infty \frac{d\omega}{\omega} \int d^3r' \perp G_{\lambda}(\mathbf{r}, \mathbf{r'}, \omega) \cdot \hat{f}^\dagger_\lambda(\mathbf{r'}, \omega) + \text{H.c.}
\]  

(39)  

(40)

Note that the longitudinal (transverse) part of a vector field is given by

\[
F^{\parallel(\perp)}(\mathbf{r}) = \int d^3r' \delta^{\parallel(\perp)}(\mathbf{r} - \mathbf{r'}) \cdot F(\mathbf{r'}),
\]

where

\[
\delta^{\parallel}(\mathbf{r}) = -\nabla \nabla \left( \frac{1}{4\pi r} \right), \quad \delta^{\perp}(\mathbf{r}) = \delta(\mathbf{r}) \mathbf{l} - \delta^{\parallel}(\mathbf{r})
\]

(41)  

(42)

(and for a tensor field accordingly).

The commutation relations for the electromagnetic fields can be deduced from the commutation relations for the dynamical variables \(\hat{f}_\lambda(r, \omega)\) and \(\hat{f}^\dagger_\lambda(r, \omega)\) as given by Eqs. (28) and (29). In particular, it can be shown [437,438] that the electric and induction fields obey the well-known (equal-time) commutation relations

\[
[\hat{E}_i(\mathbf{r}), \hat{B}_{i'}(\mathbf{r'})] = -i\hbar \varepsilon_{0}^{-1} \epsilon_{i'i} \partial_k \delta(\mathbf{r} - \mathbf{r'}),
\]
\[
[\hat{E}_i(\mathbf{r}), \hat{E}_{i'}(\mathbf{r'})] = 0 = [\hat{B}_i(\mathbf{r}), \hat{B}_{i'}(\mathbf{r'})].
\]

(43)  

(44)

Introducing the canonical momentum field associated with the (transverse) vector potential,

\[
\hat{\Pi}(\mathbf{r}) = -\varepsilon_0 \hat{E}^{\perp}(\mathbf{r}),
\]

one can also prove that the (equal-time) commutation relations

\[
[\hat{A}_i(\mathbf{r}), \hat{\Pi}_{i'}(\mathbf{r'})] = i\hbar \delta^{\perp}_{i'i} (\mathbf{r} - \mathbf{r'}),
\]
\[
[\hat{A}_i(\mathbf{r}), \hat{A}_{i'}(\mathbf{r'})] = 0 = [\hat{\Pi}_i(\mathbf{r}), \hat{\Pi}_{i'}(\mathbf{r'})]
\]

(45)  

(46)  

(47)

are fulfilled.
It is an almost trivial consequence of the quantization scheme that upon choosing the Hamiltonian of the combined system to be

\[ \hat{H}_{mf} = \sum_{\lambda=\epsilon,m} \int d^3r \int_0^\infty d\omega \mu_0 \omega^2 \hat{f}_\lambda(r,\omega) \cdot \hat{f}_\lambda(r,\omega), \quad (48) \]

the Heisenberg equations of motion

\[ \dot{\hat{O}} = \frac{i}{\hbar} [\hat{H}_{mf}, \hat{O}] \quad (49) \]

generate the correct Maxwell equations in the time domain,

\[ \nabla \times \hat{\mathbf{E}}(r) + \dot{\hat{\mathbf{B}}}(r) = 0, \quad (50) \]
\[ \nabla \times \hat{\mathbf{H}}(r) - \dot{\hat{\mathbf{D}}}(r) = 0. \quad (51) \]

Note that the Maxwell equations \( \nabla \cdot \hat{\mathbf{B}}(r) = 0 \) and \( \nabla \cdot \hat{\mathbf{D}}(r) = 0 \) are fulfilled by construction.

The Hilbert space can be spanned by Fock states obtained in the usual way by repeated application of the creation operators \( \hat{f}_\lambda^\dagger(r,\omega) \) on the ground state \(|\{0\}\rangle\) which is defined by

\[ \hat{f}_\lambda(r,\omega)|\{0\}\rangle = 0 \quad \forall \lambda, r, \omega. \quad (52) \]

Note that the ground state includes the vacuum state of the medium-assisted electromagnetic field. In particular, from Eq. (30) together with the commutation relations (28) and (29) we derive, on using the integral relation (34),

\[ \langle \{0\}| \hat{E}_\nu(r,\omega) \hat{E}_\nu^\dagger(r',\omega')|\{0\}\rangle = \pi^{-1}\mu_0 \omega^2 \delta(\omega - \omega') \text{Im} G_{ii'}(r, r', \omega), \quad (53) \]

which reveals that the vacuum fluctuations of the electric field are determined by the imaginary part of the Green tensor—in full agreement with the fluctuation-dissipation theorem.

As already mentioned, it is assumed that \( \text{Im} \varepsilon(r, \omega) > 0 \) and \( \text{Im} \mu(r, \omega) > 0 \) everywhere. Even in almost empty regions or regions where absorption is very small and can be neglected, the imaginary parts of the permittivity and permeability must not be set equal to zero in the integrands of expressions of the type (33). To allow for empty-space regions, the limits \( \text{Im} \varepsilon(r, \omega) \rightarrow 0 \) and \( \text{Im} \mu(r, \omega) \rightarrow 0 \) may be performed \textit{a posteriori}, i.e., after taking the desired expectation values and having performed all spatial integrals. In this sense the theory provides the quantized electromagnetic field in the presence of an arbitrary arrangement of linear, causal magnetodielectric bodies characterized by their permittivities and permeabilities, where \( \text{Im} \varepsilon(r, \omega) \geq 0 \) and \( \text{Im} \mu(r, \omega) \geq 0 \).
2.2 Atom–field interaction

Let us consider a system of nonrelativistic particles of masses $m_\alpha$ and charges $q_\alpha$ which form an atomic system, e.g., an atom or a molecule, interacting with the medium-assisted electromagnetic field. The Hamiltonian governing the dynamics of the atomic system (briefly referred to as atom in the following) in the absence of the medium-assisted electromagnetic field is commonly given in the form

$$
\hat{H}_{at} = \sum_\alpha \frac{\hat{p}_\alpha^2}{2m_\alpha} + \frac{1}{2} \int \mathrm{d}^3r \hat{\rho}_{at}(\mathbf{r})\hat{\varphi}_{at}(\mathbf{r}),
$$

(54)

where $\hat{\rho}_{at}(\mathbf{r})$ and $\hat{\varphi}_{at}(\mathbf{r})$, respectively, are the charge density and the scalar potential which are attributed to the atom,

$$
\hat{\rho}_{at}(\mathbf{r}) = \sum_\alpha q_\alpha \delta(\mathbf{r} - \mathbf{\hat{r}}_\alpha),
$$

(55)

$$
\hat{\varphi}_{at}(\mathbf{r}) = \int \frac{\mathrm{d}^3r'}{4\pi \varepsilon_0|\mathbf{r} - \mathbf{r}'|} \frac{\hat{\rho}_{at}(\mathbf{r}')}{4\pi \varepsilon_0|\mathbf{r} - \mathbf{r}'|},
$$

(56)

and the standard commutation relations

$$
[\hat{r}_{\alpha i}, \hat{p}_{\alpha' i'}] = i\hbar \delta_{\alpha \alpha'} \delta_{ii'},
$$

(57)

$$
[\hat{r}_{\alpha i}, \hat{r}_{\alpha' i'}] = 0 = [\hat{p}_{\alpha i}, \hat{p}_{\alpha' i'}]
$$

(58)

hold. Obviously, $\hat{\varphi}_{at}(\mathbf{r})$ and $\hat{\rho}_{at}(\mathbf{r})$ obey the equation

$$
\varepsilon_0 \Delta \hat{\varphi}_{at}(\mathbf{r}) = -\hat{\rho}_{at}(\mathbf{r}),
$$

(59)

and the continuity equation

$$
\dot{\hat{\rho}}_{at}(\mathbf{r}) + \nabla \cdot \hat{\mathbf{j}}_{at}(\mathbf{r}) = 0
$$

(60)

is fulfilled, where the atomic current density $\hat{\mathbf{j}}_{at}(\mathbf{r})$ reads

$$
\hat{\mathbf{j}}_{at}(\mathbf{r}) = \frac{1}{2} \sum_\alpha q_\alpha \left[ \hat{\mathbf{r}}_\alpha \delta(\mathbf{r} - \mathbf{\hat{r}}_\alpha) + \delta(\mathbf{r} - \mathbf{\hat{r}}_\alpha) \hat{\mathbf{r}}_\alpha \right].
$$

(61)

It may be useful [443,444] to introduce center-of-mass and relative coordinates

$$
\mathbf{\hat{r}}_A = \sum_\alpha \frac{m_\alpha}{m_A} \mathbf{\hat{r}}_\alpha, \quad \mathbf{\hat{r}}_\alpha = \mathbf{\hat{r}}_\alpha - \mathbf{\hat{r}}_A
$$

(62)

($m_A = \sum_\alpha m_\alpha$), with the appropriate associated momenta being

$$
\mathbf{\hat{p}}_A = \sum_\alpha \mathbf{\hat{p}}_\alpha, \quad \mathbf{\hat{p}}_\alpha = \mathbf{\hat{p}}_\alpha - \frac{m_\alpha}{m_A} \mathbf{\hat{p}}_A.
$$

(63)
Combining Eqs. (54) and (63), the atomic Hamiltonian may be written in the form
\[
\hat{H}_{\text{at}} = \frac{\hat{p}_{A}^2}{2m_{A}} + \sum_{\alpha} \frac{\hat{p}_{\alpha}^2}{2m_{\alpha}} + \frac{1}{2} \int d^{3}r \hat{\rho}_{\text{at}}(\mathbf{r}) \hat{\varphi}_{\text{at}}(\mathbf{r})
\]
\[
= \frac{\hat{p}_{A}^2}{2m_{A}} + \sum_{n} E_{n} |n \rangle \langle n |,
\]
where \(E_{n}\) and \(|n \rangle\) are the eigenenergies and eigenstates of the internal Hamiltonian. From the commutation relations (57) and (58) it then follows that the nonvanishing commutators of the new variables are
\[
[\hat{r}_{\alpha i}, \hat{p}_{A'j}] = i\hbar \delta_{ij'},
\]
\[
[\hat{p}_{\alpha i}, \hat{p}_{A'j'}] = i\hbar \delta_{ii'} \left( \delta_{\alpha \alpha'} - \frac{m_{\alpha'}}{m_{A}} \right).
\]
In particular, when \(m_{\alpha'}/m_{A} \ll 1\), then
\[
[\hat{r}_{\alpha i}, \hat{p}_{\alpha'j'}] \simeq i\hbar \delta_{ii'} \delta_{\alpha \alpha'}.
\]

Further atomic quantities that will be of interest are the atomic polarization \(\hat{P}_{\text{at}}(\mathbf{r})\) and magnetization \(\hat{M}_{\text{at}}(\mathbf{r})\) [445],
\[
\hat{P}_{\text{at}}(\mathbf{r}) = \sum_{\alpha} q_{\alpha} \hat{r}_{\alpha} \int_{0}^{1} d\sigma \left( \mathbf{r} - \hat{r}_{A} - \sigma \hat{r}_{\alpha} \right),
\]
\[
\hat{M}_{\text{at}}(\mathbf{r}) = \frac{1}{2} \sum_{\alpha} q_{\alpha} \int_{0}^{1} d\sigma \left[ \delta(\mathbf{r} - \hat{r}_{A} - \sigma \hat{r}_{\alpha}) \hat{r}_{\alpha} \times \hat{r}_{\alpha} - \hat{r}_{\alpha} \times \hat{r}_{\alpha} \delta(\mathbf{r} - \hat{r}_{A} - \sigma \hat{r}_{\alpha}) \right],
\]
and it can be shown that for neutral atoms, the atomic charge and current densities are related to the atomic polarization and magnetization according to
\[
\hat{\rho}_{\text{at}}(\mathbf{r}) = -\nabla \cdot \hat{P}_{\text{at}}(\mathbf{r})
\]
and
\[
\hat{j}_{\text{at}}(\mathbf{r}) = \hat{\mathbf{p}}_{\text{at}}(\mathbf{r}) + \nabla \times \hat{M}_{\text{at}}(\mathbf{r}) + \hat{j}_{\mathbf{r}}(\mathbf{r}),
\]
where
\[
\hat{j}_{\mathbf{r}}(\mathbf{r}) = \frac{1}{2} \nabla \times \left[ \hat{P}_{\text{at}}(\mathbf{r}) \times \hat{r}_{A} - \hat{r}_{A} \times \hat{P}_{\text{at}}(\mathbf{r}) \right],
\]
which is due to the center-of-mass motion, is known as the Röntgen current density [253,443]. Note that Eqs. (59) and (70) imply that
\[
\varepsilon_{0} \nabla \hat{\varphi}_{\text{at}}(\mathbf{r}) = -\hat{\mathbf{p}}_{\text{at}}(\mathbf{r}).
\]

Expanding the delta functions in Eqs. (68) and (69) in powers of the relative coordinates \(\mathbf{r}_{\alpha}\), we see that the leading-order terms are the electric and
magnetic dipole densities associated with the atom,
\begin{align}
\hat{P}_{at}(r) &= \hat{d}\delta(r - \hat{r}_A), \\
\hat{M}_{at}(r) &= \hat{m}\delta(r - \hat{r}_A),
\end{align}
(74)
(75)
where the electric and magnetic atomic dipole moments read
\begin{align}
\hat{d} &= \sum_{\alpha} q_{\alpha} \hat{r}_{\alpha} = \sum_{\alpha} q_{\alpha} \hat{r}_{\alpha}, \\
\hat{m} &= \frac{1}{4} \sum_{\alpha} q_{\alpha} \left( \hat{r}_{\alpha} \times \hat{r}_{\alpha} - \hat{r}_{\alpha} \times \hat{r}_{\alpha} \right).
\end{align}
(76)
(77)
Note that the second equality in Eq. (76) only holds for neutral atoms. Using the atomic Hamiltonian (64) together with the commutation relation (66) and the definition (63), one can easily verify the useful relation
\[ \sum_{\alpha} \frac{q_{\alpha}}{m_{\alpha}} \langle m | \hat{p}_{\alpha} | n \rangle = i\omega_{mn} d_{mn} \]
(78)
[\omega_{mn} = (E_m - E_n)/\hbar, \quad d_{mn} = \langle m | d | n \rangle],
which in turn implies the well-known sum rule
\[ \frac{1}{2\hbar} \sum_{m} \omega_{mn} (d_{mm}d_{mn} + d_{mn}d_{mm}) = \sum_{\alpha} \frac{q_{\alpha}^2}{2m_{\alpha}} I. \]
(79)

2.2.1 Minimal coupling

Having established the separate Hamiltonians of the medium-assisted field and the atom, we next consider the atom–field interaction. According to the minimal coupling scheme (cf., e.g., Ref. [253]), this may be done by making the replacement \( \hat{p}_{\alpha} \rightarrow \hat{p}_{\alpha} - q_{\alpha} \hat{A}(\hat{r}_{\alpha}) \) in the atomic Hamiltonian (54), summing the Hamiltonians of the medium-assisted field and the atom and adding the Coulomb interaction of the atom with the medium-assisted field, leading to [437,444]
\[ \hat{H} = \sum_{\lambda = e,m} \int d^3 r \int_0^\infty d\omega \hbar \omega \hat{f}_{\lambda}^1(r, \omega) \cdot \hat{f}_{\lambda}(r, \omega) + \frac{1}{2} \sum_{\alpha} m_{\alpha}^{-1} \left[ \hat{p}_{\alpha} - q_{\alpha} \hat{A}(\hat{r}_{\alpha}) \right]^2 \\
+ \frac{1}{2} \int d^3 r \hat{\rho}_{at}(r) \hat{\phi}_{at}(r) + \int d^3 r \hat{\rho}_{at}(r) \hat{\phi}(r) \\
= \hat{H}_{mf} + \hat{H}_{at} + \hat{H}_{int}, \]
(80)
(81)
where \( \hat{\phi}(r) \) and \( \hat{A}(r) \) must be thought of as being expressed in terms of the dynamical variables \( \hat{f}_{\lambda}^1(r, \omega) \) and \( \hat{f}_{\lambda}^2(r, \omega) \) according to Eqs. (39) and (40). Hence, the atom–field interaction energy reads
\[ \hat{H}_{int} = \sum_{\alpha} q_{\alpha} \hat{\phi}(\hat{r}_{\alpha}) - \sum_{\alpha} \frac{q_{\alpha}}{m_{\alpha}} \hat{p}_{\alpha} \cdot \hat{A}(\hat{r}_{\alpha}) + \sum_{\alpha} \frac{q_{\alpha}^2}{2m_{\alpha}} \hat{A}^2(\hat{r}_{\alpha}). \]
(82)
Note that the scalar product of $\mathbf{p}_\alpha$ and $\hat{\mathbf{A}}(\hat{\mathbf{r}}_\alpha)$ commutes in the Coulomb gauge.

The total electromagnetic field in the presence of the atom reads

$$
\hat{\mathbf{E}}(\mathbf{r}) = \mathbf{E}(\mathbf{r}) - \nabla \hat{\varphi}_{\text{at}}(\mathbf{r}), \quad \hat{\mathbf{B}}(\mathbf{r}) = \mathbf{B}(\mathbf{r}),
$$

$$
\hat{\mathbf{D}}(\mathbf{r}) = \mathbf{D}(\mathbf{r}) - \varepsilon_0 \nabla \hat{\varphi}_{\text{at}}(\mathbf{r}), \quad \hat{\mathbf{H}}(\mathbf{r}) = \mathbf{H}(\mathbf{r}).
$$

(83)

(84)

Obviously, $\hat{\mathbf{B}}(\mathbf{r})$ and $\hat{\mathbf{D}}(\mathbf{r})$ obey the Maxwell equations

$$
\nabla \cdot \hat{\mathbf{B}}(\mathbf{r}) = 0,
$$

(85)

$$
\nabla \cdot \hat{\mathbf{D}}(\mathbf{r}) = \hat{\rho}_{\text{at}}(\mathbf{r}),
$$

(86)

and it is a straightforward calculation [437,444] to verify that the Hamiltonian (80) generates the remaining two Maxwell equations

$$
\nabla \times \hat{\mathbf{E}}(\mathbf{r}) + \hat{\mathbf{B}}(\mathbf{r}) = 0,
$$

(87)

$$
\nabla \times \hat{\mathbf{H}}(\mathbf{r}) - \hat{\mathbf{D}}(\mathbf{r}) = \hat{\mathbf{j}}_{\text{at}}(\mathbf{r}),
$$

(88)

and the Newton equations of motion for the charged particles,

$$
m_{\alpha} \ddot{\mathbf{r}}_\alpha = q_{\alpha} \hat{\mathbf{E}}(\mathbf{r}_\alpha) + \frac{1}{2} q_{\alpha} \left[ \dot{\mathbf{r}}_\alpha \times \hat{\mathbf{B}}(\mathbf{r}_\alpha) - \hat{\mathbf{B}}(\mathbf{r}_\alpha) \times \dot{\mathbf{r}}_\alpha \right],
$$

(89)

where

$$
\dot{\mathbf{r}}_\alpha = m_{\alpha}^{-1} \left[ \mathbf{p}_\alpha - q_{\alpha} \hat{\mathbf{A}}(\hat{\mathbf{r}}_\alpha) \right].
$$

(90)

In many cases of practical interest one may assume that the atom is small compared to the wavelength of the relevant electromagnetic field. It is hence useful to employ center-of-mass and relative coordinates [Eqs. (62) and (63)] and apply the long-wavelength approximation by performing a leading-order expansion of the interaction Hamiltonian (82) in terms of the relative particle coordinates $\hat{\mathbf{r}}_\alpha$. Considering a neutral atom and recalling Eq. (39), we easily derive

$$
\hat{H}_{\text{int}} = -\mathbf{d} \cdot \hat{\mathbf{E}}(\hat{\mathbf{r}}_A) - \sum_{\alpha} \frac{q_{\alpha}}{m_{\alpha}} \mathbf{p}_\alpha \cdot \hat{\mathbf{A}}(\hat{\mathbf{r}}_\alpha) + \sum_{\alpha} \frac{q_{\alpha}^2}{2m_{\alpha}} \hat{\mathbf{A}}^2(\hat{\mathbf{r}}_\alpha).
$$

(91)

Note that the last term on the r.h.s. of Eq. (91) is independent of the relative particle coordinates, and hence does not act on the internal state of the atom. When considering processes caused by strong resonant transitions between different internal states of the atom, it may therefore be neglected.
2.2.2 Multipolar coupling

An equivalent description of the atom–field interaction that is widely used is based on the multipolar-coupling Hamiltonian.\(^\dag\) For a neutral atom, the transition from the minimal-coupling Hamiltonian (80) to the multipolar-coupling Hamiltonian is a canonical transformation of the dynamical variables corresponding to a unitary transformation, with the respective transformation operator being given by

\[
\hat{U} = \exp \left[ \frac{i}{\hbar} \int d^3r \hat{P}_{\text{at}}(r) \cdot \hat{A}(r) \right], \tag{92}
\]

with \(\hat{A}(r)\) and \(\hat{P}_{\text{at}}(r)\) being defined by Eqs. (40) and (68), respectively. This transformation is commonly known as the Power–Zienau–Woolley transformation \([447,448]\); obviously it does not change \(\hat{r}_\alpha'\),

\[
\hat{r}_\alpha' = \hat{U} \hat{r}_\alpha \hat{U}^\dagger = \hat{r}_\alpha, \tag{93}
\]

and a straightforward calculation yields \([437,444]\)

\[
\hat{p}_\alpha' = \hat{U} \hat{p}_\alpha \hat{U}^\dagger = \hat{p}_\alpha - q_\alpha \hat{A}(\hat{r}_\alpha) - \int d^3r \hat{\Xi}_\alpha(r) \times \hat{B}(r) \tag{94}
\]

and

\[
\hat{f}'_\lambda(r, \omega) = \hat{U} \hat{f}_\lambda(r, \omega) \hat{U}^\dagger = \hat{f}_\lambda(r, \omega) + \frac{1}{\hbar \omega} \int d^3r' \hat{P}_\text{at}^\dagger(r') \cdot G^*_\lambda(r', r, \omega), \tag{95}
\]

where

\[
\hat{\Xi}_\alpha(r) = q_\alpha \hat{r}_\alpha \int_0^1 d\sigma \sigma \delta(\mathbf{r} - \mathbf{r}_A - \sigma \hat{r}_\alpha) - \frac{m_\alpha}{m_A} \sum_\beta q_\beta \hat{r}_\beta \int_0^1 d\sigma \sigma \delta(\mathbf{r} - \mathbf{r}_A - \sigma \hat{r}_\beta) + \frac{m_\alpha}{m_A} \hat{P}_{\text{at}}(r). \tag{96}
\]

Now we may express the minimal-coupling Hamiltonian (80) in terms of the transformed variables to obtain the multipolar-coupling Hamiltonian in the form

\[
\hat{H} = \sum_{\lambda=e,m} \int d^3r \int_0^\infty d\omega \hbar \omega \hat{f}'_\lambda(r, \omega) \cdot \hat{f}'_\lambda(r, \omega) + \frac{1}{2\varepsilon_0} \int d^3r \hat{P}^2_\text{at}(r)
\]

\[
+ \sum_\alpha \frac{1}{2m_\alpha} \left[ \hat{p}_\alpha' + \int d^3r \hat{\Xi}'_\alpha(r) \times \hat{B}'(r) \right]^2 - \int d^3r \hat{P}'_\text{at}(r) \cdot \hat{E}'(r). \tag{97}
\]

\(^\dag\)For an extension of the formulas given below to the case of more than one atoms, see Ref. [446].
Here, $\hat{E}'(r)$ and $\hat{B}'(r)$, respectively, are given by Eqs. (33) and (36), with $\hat{f}(r, \omega) [\hat{F}(r, \omega)]$ being replaced with $\hat{f}'(r, \omega) [\hat{F}'(r, \omega)]$. Note that $\hat{r}'_\alpha = \hat{r}_\alpha$, $\hat{r}'_A = \hat{r}_A$, $\hat{P}'_\alpha = \hat{P}_\alpha$, $\hat{P}'_A = \hat{P}_A$, $\hat{\Xi}'_\alpha(r) = \hat{\Xi}_\alpha(r)$, $\hat{B}'(r) = \hat{B}(r)$, but

$$
\hat{E}'(r) = \hat{E}(r) + \varepsilon_0^{-1} \hat{P}'_\alpha(r),
$$

(98)

which means that the transformed (medium-assisted) electric field $\hat{E}'(r)$ has the physical meaning of a displacement field in contrast to $\hat{E}(r)$, which has the physical meaning of an electric field.

The Hamiltonian (97) can be decomposed into three parts,

$$
\hat{H} = \hat{H}_{\text{mf}} + \hat{H}_{\text{at}} + \hat{H}_{\text{int}'},
$$

(99)

where $\hat{H}_{\text{mf}}$ is given by Eq. (48) with the primed variables in place of the unprimed ones,

$$
\hat{H}_{\text{mf}} = \sum_{\lambda=e,m} \int d^3 r \int_0^\infty d\omega \hbar \omega \hat{f}'(r, \omega) \cdot \hat{f}'(r, \omega),
$$

(100)

$\hat{H}_{\text{at}}$ is the atomic Hamiltonian,

$$
\hat{H}_{\text{at}} = \frac{\hat{P}'_A^2}{2m_A} + \sum_\alpha \frac{\hat{P}'_\alpha^2}{2m_\alpha} + \frac{1}{2\varepsilon_0} \int d^3 r \hat{P}'_\alpha^2(r)
$$

$$
= \frac{\hat{P}'_A^2}{2m_A} + \sum_n E'_n |n' \rangle \langle n'|,
$$

(101)

and $\hat{H}_{\text{int}}$ is the coupling term,

$$
\hat{H}_{\text{int}} = -\int d^3 r \hat{P}'_\alpha(r) \cdot \hat{E}'(r) - \int d^3 r \hat{M}'_\alpha(r) \cdot \hat{B}'(r)
$$

$$
+ \sum_\alpha \frac{1}{2m_\alpha} \left[ \int d^3 r \hat{\Xi}'_\alpha(r) \times \hat{B}'(r) \right]^2 + \frac{1}{m_A} \int d^3 r \hat{p}'_A \cdot \hat{P}'_A \times \hat{B}'(r),
$$

(102)

where

$$
\hat{M}'_\alpha(r) = \sum_\alpha \frac{q_\alpha}{2m_\alpha} \int_0^1 d\sigma \sigma \left[ \delta(r - \hat{r}'_A - \sigma \hat{r}'_\alpha) \hat{p}'_\alpha \times \hat{p}'_\alpha - \hat{p}'_\alpha \times \hat{r}'_\alpha \delta(r - \hat{r}'_A - \sigma \hat{r}'_\alpha) \right].
$$

(103)

Note that in contrast to the physical magnetization $\hat{M}_\alpha(r)$ [Eq. (69)], $\hat{M}'_\alpha(r)$ is defined in terms of the canonically conjugated momenta rather than the velocities, as is required in a canonical formalism. The Hamiltonian (97) implies the relation

$$
m_\alpha \hat{r}'_\alpha = \hat{p}'_\alpha + \int d^3 r \hat{\Xi}'_\alpha(r) \times \hat{B}'(r),
$$

(104)
and it is not difficult to see [recall Eqs. (90) and (94)] that \( m_\alpha \ddot{r}_\alpha = m_\alpha \dot{r}_\alpha \). It should be pointed out that the eigenenergies \( E'_\alpha \) of the internal Hamiltonian in Eq. (101) may be different from the corresponding ones of the internal Hamiltonian in Eq. (64), because of the additional term contained in

\[
\frac{1}{2\varepsilon_0} \int d^3r \, \dot{\mathbf{P}}_{\alpha}^2(r) = \frac{1}{2} \int dr \, \dot{\rho}_{\alpha}(r) \phi_{\alpha}(r) + \frac{1}{2\varepsilon_0} \int d^3r \left[ \dot{\mathbf{P}}_{\alpha}(r) \right]^2. \tag{105}
\]

Accordingly, the eigenstates of the two internal Hamiltonians are not related to each other via the unitary transformation \( \tilde{U} \) [Eq. (92)] in general.

One of the advantages of the multipolar coupling scheme is the fact that it allows for a systematic expansion in terms of the electric and magnetic multipole moments of the atom. In particular, in the long-wavelength approximation, by retaining only the leading-order terms in the relative coordinates \( \mathbf{r}'_\alpha \), the interaction energy (102) reads

\[
\hat{H}_{\text{int}} = - \mathbf{d}' \cdot \hat{\mathbf{E}}'(\mathbf{r}'_\alpha) - \mathbf{m}' \cdot \mathbf{B}'(\mathbf{r}'_\alpha) + \sum_{\alpha} \frac{q_\alpha^2}{8m_\alpha} \left[ \mathbf{r}'_\alpha \times \mathbf{B}'(\mathbf{r}'_\alpha) \right]^2
+ \frac{3}{8m_A} \left[ \mathbf{d}' \times \mathbf{B}'(\mathbf{r}'_\alpha) \right]^2 + \frac{1}{m_A} \mathbf{p}'_\alpha \cdot \mathbf{d}' \times \mathbf{B}'(\mathbf{r}'_\alpha), \tag{106}
\]

where

\[
\mathbf{m}' = \sum_{\alpha} \frac{q_\alpha}{4m_\alpha} \left( \mathbf{r}'_\alpha \times \mathbf{p}'_\alpha - \mathbf{p}'_\alpha \times \mathbf{r}'_\alpha \right). \tag{107}
\]

Note that, in contrast to \( \mathbf{m}' \) [Eq. (77)], \( \mathbf{m}' \) is defined in terms of the canonical momenta. The first two terms on the r.h.s. of Eq. (106) represent electric and magnetic dipole interactions, respectively, the next two terms describe the (generalized) diamagnetic interaction, and the last term is the Röntgen interaction due to the center-of-mass motion. For nonmagnetic atoms, Eq. (107) reduces to the interaction Hamiltonian in electric-dipole approximation, which is given by

\[
\hat{H}_{\text{int}} = - \mathbf{d}' \cdot \hat{\mathbf{E}}'(\mathbf{r}'_\alpha) + \frac{\mathbf{p}'_\alpha}{m_A} \cdot \mathbf{d}' \times \mathbf{B}'(\mathbf{r}'_\alpha), \tag{108}
\]

or

\[
\hat{H}_{\text{int}} = - \mathbf{d}' \cdot \hat{\mathbf{E}}'(\mathbf{r}'_\alpha) \tag{109}
\]

—in cases where the influence of the center-of-mass motion on the atom–field interaction does not need to be taken into account.
3 Forces on bodies

Electromagnetic forces are Lorentz forces. As known, the total Lorentz force \( \mathbf{F}_L \) acting on the matter contained in a volume \( V \) is given by

\[
\mathbf{F}_L = \int_V d^3r \left[ \dot{\rho}(r) \mathbf{E}(r) + \dot{\mathbf{j}}(r) \times \mathbf{B}(r) \right].
\]  

(110)

Here, the electromagnetic field acts on the total charge and current densities \( \dot{\rho}(r) \) and \( \dot{\mathbf{j}}(r) \) present in the volume, which may in general include the internal charge and current densities \( \dot{\rho}_m(r) \) and \( \dot{\mathbf{j}}_m(r) \) attributed to a medium [Eqs. (7) and (8)] as well as those due to additional sources, such as \( \dot{\rho}_{at}(r) \) and \( \dot{\mathbf{j}}_{at}(r) \) [Eqs. (55) and (61)]. With the help of the Maxwell equations [as given by Eqs. (1)-4 with \( \dot{\rho}_m(r) \rightarrow \dot{\rho}(r), \dot{\mathbf{j}}_m(r) \rightarrow \dot{\mathbf{j}}(r) \)] one easily finds

\[
\dot{\rho}(r) \mathbf{E}(r) + \dot{\mathbf{j}}(r) \times \mathbf{B}(r) = \nabla \cdot \mathbf{T}(r) - \varepsilon_0 \frac{\partial}{\partial t} \left[ \dot{\mathbf{E}}(r) \times \dot{\mathbf{B}}(r) \right],
\]

so that

\[
\mathbf{F}_L = \int_{\partial V} \mathbf{d} \mathbf{a} \cdot \mathbf{\hat{T}}(r) - \varepsilon_0 \frac{d}{dt} \int_V d^3r \dot{\mathbf{E}}(r) \times \dot{\mathbf{B}}(r),
\]

(112)

where the stress tensor

\[
\mathbf{T}(r) = \varepsilon_0 \dot{\mathbf{E}}(r) \dot{\mathbf{E}}(r) + \mu_0^{-1} \dot{\mathbf{B}}(r) \dot{\mathbf{B}}(r) - \frac{1}{2} \left[ \varepsilon_0 \dot{\mathbf{E}}^2(r) + \mu_0^{-1} \dot{\mathbf{B}}^2(r) \right] \]

(113)

has been introduced. In particular, if the volume integral in the second term on the r.h.s. of Eq. (112) does not depend on time, then the total force reduces to the surface integral

\[
\mathbf{F}_L = \int_{\partial V} \mathbf{d} \mathbf{F}_L,
\]

(114)

where

\[
\mathbf{d} \mathbf{F}_L = \mathbf{d} \mathbf{a} \cdot \mathbf{\hat{T}}(r) = \mathbf{T}(r) \cdot \mathbf{d} \mathbf{a}
\]

(115)

may be regarded as the infinitesimal force element acting on an infinitesimal surface element \( \mathbf{d} \mathbf{a} \). Note that a constant term in the stress tensor does not contribute to the integral in Eq. (114) and can therefore be omitted.

If the Minkowski stress tensor

\[
\mathbf{T}^{(M)}(r) = \dot{\mathbf{D}}(r) \mathbf{E}(r) + \dot{\mathbf{H}}(r) \mathbf{B}(r) - \frac{1}{2} \left[ \dot{\mathbf{D}}(r) \cdot \mathbf{E}(r) + \dot{\mathbf{H}}(r) \cdot \mathbf{B}(r) \right] \]

\[
\mathbf{T}(r) = \dot{\mathbf{P}}(r) \mathbf{E}(r) - \dot{\mathbf{M}}(r) \mathbf{B}(r) - \frac{1}{2} \left[ \dot{\mathbf{P}}(r) \cdot \mathbf{E}(r) - \dot{\mathbf{M}}(r) \cdot \mathbf{B}(r) \right] \]

(116)

(which agrees with Abraham’s stress tensor [449]) is used in Eq. (114) [together
with Eq. (115)] instead of $\mathbf{T}(r)$ to calculate the force, one finds that
\[
d\mathbf{F}^{(M)} = da \cdot \mathbf{T}^{(M)}(r)
- \frac{1}{2} \left[ \mathbf{P}(r) \cdot \dot{\mathbf{E}}(r) - \mathbf{M}(r) \cdot \dot{\mathbf{B}}(r) \right]
\]
and it is seen that in general
\[
d\mathbf{F}_L \neq da \cdot \mathbf{T}^{(M)}(r). \tag{117}
\]
That is to say, the use of the Minkowski stress tensor is expected not to yield the Lorentz force, in general. Indeed, a careful analysis and interpretation of classical electromagnetic force experiments [450, 451, 452, 453, 454, 455, 456, 457] shows that the (energy–momentum four-tensor associated with the) Lorentz force passes the theoretical and experimental tests and qualifies for a correct description of the energy–momentum properties of the electromagnetic field in macroscopic electrodynamics [458] (also see Secs. 3.1 and 3.2).

In classical electrodynamics, electrically neutral material bodies at zero temperature which do not carry a permanent polarization and/or magnetization are not subject to a Lorentz force in the absence of external electromagnetic fields. As already noted in Sec. 1.1, the situation changes in quantum electrodynamics, since the ground-state fluctuations of the body-assisted electromagnetic field and the body’s polarization/magnetization charge and current densities can give rise to a nonvanishing ground-state expectation value of the Lorentz force—the Casimir force [459]
\[
\mathbf{F} = \int_V d^3r \left\langle \left\{ \mathbf{\hat{P}}(r) \mathbf{E}(r') + \mathbf{\hat{j}}(r) \times \mathbf{B}(r') \right\} \right| \{0\} \right\rangle_{r' \to r}. \tag{119}
\]
Here, the coincidence limit $r' \to r$ must be performed in such a way that unphysical (divergent) self-force contributions are discarded after the vacuum expectation value has been calculated for $r' \neq r$, an explicit prescription will be given below Eq. (124).

To calculate the Casimir force, let us consider linear media that locally respond to the electromagnetic field and can be characterized by a spatially varying complex permittivity $\varepsilon(r, \omega)$ and a spatially varying complex permeability $\mu(r, \omega)$. Following Sec. 2.1, we may write the medium-assisted electric and induction fields in the form of Eqs. (33) and (36). Provided that the volume of interest $V$ does not contain any additional charges or currents, the charge and current densities that are subject to the Lorentz force (110) are the internal ones, $\mathbf{\hat{\rho}}(r) = \hat{\rho}_{\text{in}}(r)$ and $\mathbf{\hat{j}}(r) = \hat{\mathbf{j}}_{\text{in}}(r)$ [recall Eqs. (7) and (8)]. Making use of Eqs. (13) and (14) together with Eqs. (17)–(21), one can easily see that
\[
\mathbf{\hat{\rho}}(r, \omega) = -\varepsilon_0 \nabla \cdot \left\{ [\varepsilon(r, \omega) - 1] \mathbf{\hat{E}}(r, \omega) \right\} + (i\omega)^{-1} \nabla \cdot \mathbf{\hat{\mathbf{j}}}_{\text{in}}(r, \omega) \tag{120}
\]
and
\[
\hat{J}(\mathbf{r}, \omega) = -i\omega \varepsilon_0 [\varepsilon(\mathbf{r}, \omega) - 1] \mathbf{E}(\mathbf{r}, \omega) \\
+ \nabla \times \left\{ \kappa_0 [1 - \kappa(\mathbf{r}, \omega)] \mathbf{B}(\mathbf{r}, \omega) \right\} + \hat{J}_N(\mathbf{r}, \omega).
\]  
(121)

Taking into account that \( \mathbf{E}(\mathbf{r}, \omega) \) and \( \mathbf{B}(\mathbf{r}, \omega) \) can be given in the forms (19) and (35), respectively, and that the Green tensor \( \mathbf{G}(\mathbf{r}, \mathbf{r}', \omega) \) obeys the differential equation (21), we may perform Eqs. (120) and (121) to obtain
\[
\hat{j}(\mathbf{r}, \omega) = \frac{i\omega}{c^2} \int d^3r' \nabla \cdot \mathbf{G}(\mathbf{r}, \mathbf{r}', \omega) \cdot \hat{j}_N(\mathbf{r}', \omega),
\]  
(122)
\[
\hat{j}(\mathbf{r}, \omega) = \int d^3r' \left[ \nabla \times \nabla \times \frac{\omega^2}{c^2} \right] \mathbf{G}(\mathbf{r}, \mathbf{r}', \omega) \cdot \hat{j}_N(\mathbf{r}', \omega).
\]  
(123)

In this way, the fields \( \hat{j}(\mathbf{r}, \omega), \hat{J}(\mathbf{r}, \omega), \mathbf{E}(\mathbf{r}, \omega) \) [Eq. (19)], and \( \mathbf{B}(\mathbf{r}, \omega) \) [Eq. (20)] are expressed in terms of the noise current density \( \hat{j}_N(\mathbf{r}, \omega) \). Making use of Eq. (16) together with Eqs. (26) and (27) and recalling the commutation relations (28) and (29), one can easily calculate the ground-state correlation function \( \langle \{0\} \hat{j}_N(\mathbf{r}, \omega) \hat{j}_N(\mathbf{r}', \omega) \{0\} \rangle \), which can then be used, on recalling Eqs. (19), (20), (122), and (123), to calculate all the correlation functions relevant to the Casimir force, as given by Eq. (119). The result is [460]
\[
\mathbf{F} = -\frac{\hbar}{\pi} \int_V d^3r \int_0^\infty d\xi \left\{ \frac{\xi^2}{c^2} \nabla \cdot \text{Im} \mathbf{G}(\mathbf{r}, \mathbf{r}', i\xi) \\
+ \left[ \nabla \times \nabla \times + \frac{\xi^2}{c^2} \right] \text{Im} \mathbf{G}(\mathbf{r}, \mathbf{r}', i\xi) \times \overleftrightarrow{\nabla} \right\}_{\mathbf{r}' \rightarrow \mathbf{r}}
\]  
(124)

(\overleftrightarrow{\nabla} \text{ introduces differentiation to the left}), where it is now apparent that in the coincidence limit \( \mathbf{r}' \rightarrow \mathbf{r} \) the Green tensor has to be replaced with its scattering part at each space point. In particular, when the material in the space region \( V \) is homogeneous, then the Green tensor therein can be globally decomposed into a bulk part \( \mathbf{G}^{(0)}(\mathbf{r}, \mathbf{r}', \omega) \) and a scattering part \( \mathbf{G}^{(1)}(\mathbf{r}, \mathbf{r}', \omega) \),
\[
\mathbf{G}(\mathbf{r}, \mathbf{r}', \omega) = \mathbf{G}^{(0)}(\mathbf{r}, \mathbf{r}', \omega) + \mathbf{G}^{(1)}(\mathbf{r}, \mathbf{r}', \omega) \quad (\mathbf{r} \in V).
\]  
(125)

In this case, the coincidence limit \( \mathbf{r}' \rightarrow \mathbf{r} \) simply means that the Green tensor \( \mathbf{G}(\mathbf{r}, \mathbf{r}', \omega) \) can be globally replaced by its well-behaved scattering part \( \mathbf{G}^{(1)}(\mathbf{r}, \mathbf{r}', \omega) \).

According to Eqs. (113)–(115), the Casimir force can be equivalently rewritten as a surface integral over a stress tensor [459],
\[
\mathbf{F} = \int_{\partial V} d\mathbf{a} \cdot \mathbf{T}(\mathbf{r}, \mathbf{r}')_{\mathbf{r}' \rightarrow \mathbf{r}}.
\]  
(126)
where

\[
T(\mathbf{r}, \mathbf{r}') = \langle \{0\} | \left[ \varepsilon_0 \hat{E}(\mathbf{r}) \hat{E}(\mathbf{r}') + \mu_0^{-1} \hat{B}(\mathbf{r}) \hat{B}(\mathbf{r}') \\
- \frac{1}{2} \left[ \varepsilon_0 \hat{E}(\mathbf{r}) \cdot \hat{E}(\mathbf{r}') + \mu_0^{-1} \hat{B}(\mathbf{r}) \cdot \hat{B}(\mathbf{r}') \right] \right] | \{0\} \rangle, \quad (127)
\]

which leads to

\[
T(\mathbf{r}, \mathbf{r}') = S(\mathbf{r}, \mathbf{r}') - \frac{1}{2} \left[ \text{Tr} \, S(\mathbf{r}, \mathbf{r}') \right] I
\]

with

\[
S(\mathbf{r}, \mathbf{r}') = -\frac{\hbar}{\pi} \int_0^\infty d\xi \left[ \frac{\varepsilon^2}{c^2} G(\mathbf{r}, \mathbf{r}', i\xi) + \nabla \times G(\mathbf{r}, \mathbf{r}', i\xi) \times \nabla' \right]. \quad (129)
\]

Both Eq. (124) and Eq. (126) (together with Eqs. (128) and (129)) are valid for arbitrary bodies that linearly respond to the electromagnetic field, since the force is fully determined by the Green tensor of the classical, macroscopic Maxwell equations, with the material properties entering the force formulas only via the Green tensor. Moreover, Eqs. (124) and (129) reveal that the force is proportional to \( \hbar \) and hence represents a pure quantum effect.

### 3.1 Casimir stress in planar structures

Let us apply the theory to a planar magnetodielectric structure defined according to

\[
\varepsilon(\mathbf{r}, \omega) = \begin{cases} 
\varepsilon_-(z, \omega) & z < 0, \\
\varepsilon(\omega) & 0 < z < d, \\
\varepsilon_+(z, \omega) & z > d,
\end{cases} \quad (130)
\]

\[
\mu(\mathbf{r}, \omega) = \begin{cases} 
\mu_-(z, \omega) & z < 0, \\
\mu(\omega) & 0 < z < d, \\
\mu_+(z, \omega) & z > d.
\end{cases} \quad (131)
\]

To determine the Casimir stress in the interspace \( 0 < z < d \), we need the scattering part of the Green tensor in Eq. (129) for both spatial arguments within the interspace \( 0 < z = z' < d \). Since the component \( \mathbf{q} \) of the wave vector parallel to the interfaces is conserved and the polarizations \( \sigma = s, p \) decouple, the required Green tensor (as given in App. A) can be expressed in terms of reflection coefficients \( r_{\sigma\pm} = r_{\sigma\pm}(\omega, \mathbf{q}) \) \( (q = |\mathbf{q}|) \) referring to reflection of waves at the right \((+\rangle \) and left \((-\rangle \) wall, respectively, as seen from the interspace. Explicit (recurrence) expressions for the reflection coefficients are available if the walls are multi-slab magnetodielectrics, cf. Eqs. (A.7) and (A.8).\(^{18}\) In the simplest case of two homogeneous, semi-infinite half spaces,\(^{18}\) For continuous wall profiles, Riccati-type equations have to be solved [461].
the coefficients \( r_{\sigma \pm} \) reduce to the well-known Fresnel amplitudes, Eq. (A.10). In the case first treated by Lifshitz [354], the inter-space is empty and the walls are nonmagnetic.

For symmetry reasons it is clear that the stress tensor in the intespace \( 0 < z < d \) effectively reduces to the \( z \) component, \( T_{zz}(\mathbf{r}) \equiv T_{zz}(\mathbf{r}, \mathbf{r})_{r' \rightarrow r} \), which, upon using the Green tensor from App. A, can be given in the form [459]

\[
T_{zz}(\mathbf{r}) = \frac{\hbar}{8\pi^2} \int_{0}^{\infty} d\xi \int_{0}^{\infty} dq \frac{q}{b} \mu(i\xi)g(z, \xi, q), \quad (132)
\]

where the function \( g(z, \xi, q) \) is given by

\[
g(z, \xi, q) = 2 \left[ b^2(1 + n^{-2}) + q^2(1 - n^{-2}) \right] e^{-2bd} r_{s+} r_{s-} D_s^{-1} \\
+ 2 \left[ b^2(1 + n^{-2}) - q^2(1 - n^{-2}) \right] e^{-2bd} r_{p+} r_{p-} D_p^{-1} \\
- (b^2 - q^2)(1 - n^{-2}) \left[ e^{-2bz} r_{s-} + e^{-2b(\xi-d)z} r_{s+} \right] D_s^{-1} \\
+ (b^2 - q^2)(1 - n^{-2}) \left[ e^{-2bz} r_{p-} + e^{-2b(\xi-d)z} r_{p+} \right] D_p^{-1}, \quad (133)
\]

with

\[
n = n(i\xi) = \sqrt{\varepsilon(i\xi)\mu(i\xi)}, \quad (134)
\]

\[
b = b(\xi, q) = \sqrt{n(i\xi)\frac{\varepsilon^2}{c^2} + q^2}, \quad (135)
\]

\[
D_{\sigma} = D_{\sigma}(\xi, q) = 1 - r_{\sigma+} r_{\sigma-} e^{-2bd}, \quad \sigma = s, p. \quad (136)
\]

To further (numerically) evaluate Eq. (132), knowledge of the \( \xi \)- and \( q \)-dependence of the reflection coefficients is required, refer to Refs. [434,435,462,463,464] for a treatment of various planar systems on the basis of macroscopic QED. Let us here restrict our attention to the limit of perfectly conducting surfaces, i.e., \( r_{p \pm} = - r_{s \pm} = 1 \), and assume that the wall separation \( d \) is sufficiently large, so that the permittivity and the permeability of the medium in the intespace can be replaced by their static values \( \varepsilon \equiv \varepsilon(0) \) and \( \mu \equiv \mu(0) \). It is then not difficult to calculate the simplified integrals in Eq. (132) analytically to obtain the attractive Casimir force per unit area, \( \bar{F} = T_{zz}(d) \) [recall Eq. (126)] which acts between two perfectly reflecting plates as [459]

\[
\bar{F} = \frac{\hbar c \pi^2}{240} \sqrt{\frac{\mu}{\varepsilon}} \left( 1 - \frac{\varepsilon \mu + 1}{3\varepsilon \mu} \right) \frac{1}{d^4}, \quad (137)
\]

which reduces to Casimir and Polder’s famous formula [241]

\[
\bar{F} = \frac{\hbar c \pi^2}{240} \frac{1}{d^4} \quad (138)
\]
in the case when the interspace is empty ($\varepsilon = 1$, $\mu = 1$).

In the same approximation, the force that acts on a perfectly conducting plate in a planar cavity bounded by perfectly conducting walls and filled with a dielectric medium obviously reads

$$
\vec{F} = \frac{\hbar c \pi^2}{240} \frac{1}{\sqrt{\varepsilon}} \left( 1 - \frac{\varepsilon + 1}{3\varepsilon} \right) \left( \frac{1}{d_i^4} - \frac{1}{d_r^4} \right),
$$

(139)

where $d_i$ ($d_r$) is the left (right) plate–wall separation. On the contrary, use of the Minkowski stress tensor (116) leads to [462]

$$
\vec{F}^{(M)} = \frac{\hbar c \pi^2}{240} \frac{1}{\sqrt{\varepsilon}} \left( \frac{1}{d_i^4} - \frac{1}{d_r^4} \right).
$$

(140)

Comparing the two results, we see that $|\vec{F}| \leq |\vec{F}^{(M)}|$. Introduction of a (polarizable) medium into the interspace between the plate and the cavity walls is obviously associated with some screening, thereby reducing the force acting on the plate. Since the internal charges and currents of the interspace medium are only fully included in the Lorentz force [recall Eqs. (110)–(115)], the force based on the Minkowski stress tensor or an equivalent quantity underestimates the screening effect and is hence larger than the Lorentz force in general.

3.2 Macro- and micro-objects

Returning to the general formula (124), let us consider the Casimir force acting on dielectric matter of susceptibility $\chi(r,\omega) = \varepsilon(r,\omega) - 1$ in some particular space region $V$ in the presence of arbitrary magnetodielectric bodies (outside $V$) in more detail. If $\mathcal{G}(r, r', \omega)$ and $\mathbf{G}(r, r', \omega)$, respectively, denote the Green tensors in the absence and presence of the dielectric matter in $V$, with both of them taking into account the magnetodielectric bodies in the remaining space, the differential equation (21) for $\mathbf{G}(r, r', \omega)$ can be converted into the Dyson-type integral equation

$$
\mathbf{G}(r, r', \omega) = \overline{\mathbf{G}}(r, r', \omega) + \frac{\omega^2}{c^2} \int_V \text{d}^3 s \chi(s, \omega) \overline{\mathbf{G}}(r, s, \omega) \cdot \mathbf{G}(s, r', \omega),
$$

(141)

where, for $r \in V$, the Green tensor $\overline{\mathbf{G}}(r, r', \omega)$ satisfies the same differential equation as the free-space Green tensor,

$$
\left[ \nabla \times \nabla \times -\frac{\omega^2}{c^2} \right] \overline{\mathbf{G}}(r, r', \omega) = \delta(r - r') I,
$$

(142)
from which it follows that
\[ \frac{\omega^2}{c^2} \nabla \cdot \mathbf{G}(r, r', \omega) = -\nabla \delta(r - r'). \] (143)

Equations (141) and (143) imply \((r \in V)\)
\[ \nabla \cdot \text{Im} \mathbf{G}(r, r', \omega) = -\nabla \cdot \text{Im}[\chi(r, \omega) \mathbf{G}(r, r', \omega)]. \] (144)

In a similar way, one finds that \((r \in V)\)
\[ \left[ \nabla \times \nabla \times -\frac{\omega^2}{c^2} \right] \text{Im} \mathbf{G}(r, r', \omega) \times \hat{\nabla}' = \frac{\omega^2}{c^2} \text{Im}[\chi(r, \omega) \mathbf{G}(r, r', \omega)] \times \hat{\nabla}'. \] (145)

Substituting Eqs. (144) and (145) into Eq. (124) one can then show that the Casimir force acting on a dielectric body of volume \(V\) which is an inner part of a larger dielectric body (occupying volume \(V\)) reads [460]:
\[
\mathbf{F} = -\frac{\hbar \mu_0}{2\pi} \int_0^\infty d\xi \xi^2 \left\{ \int_{V_1} d^3r \chi(r, i\xi) \nabla \text{Tr}[\mathbf{G}(r, r', i\xi)]_{r \to r'} \right.
\]
\[\left. -2 \int_{\partial V_1} da \chi(r, i\xi) [\mathbf{G}(r, r', i\xi)]_{r \to r'} \right\}. \] (146)

In particular, in the case of an isolated dielectric body, i.e., when region \(V \supset V_1\) is empty apart from the dielectric matter contained in \(V_1\), then the surface integral can be dropped, hence
\[
\mathbf{F} = -\frac{\hbar \mu_0}{2\pi} \int_0^\infty d\xi \xi^2 \int_{V_1} d^3r \chi(r, i\xi) \nabla \text{Tr}[\mathbf{G}(r, r', i\xi)]_{r \to r'}. \] (147)

Let us briefly compare Eq. (146) with the equation is obtained if the Minkowski stress tensor is used,
\[
\mathbf{F}^{(M)} = \frac{\hbar \mu_0}{2\pi} \int_0^\infty d\xi \xi^2 \int_{V_1} d^3r \left[ \nabla \chi(r, i\xi) \right] \text{Tr}[\mathbf{G}(r, r, i\xi)]_{r \to r'}, \] (148)
which differs from Eq. (146) by a surface integral, in general [460]. Hence, the two force formulas agree in the case of an isolated body where the surface integrals do not contribute to the force and both equations reduce to Eq. (147). In contrast to Eq. (146), application of Eq. (148) to any inner, homogeneous part of a body leads to the paradoxical result that the force identically vanishes, because of \(\nabla \chi(r, i\xi) = 0\). In other words, the only atoms that are subject to a force are those at the surface of the body. On the contrary, it is known that the van der Waals forces on all atoms contribute to the Casimir force (Sec. 3.2.1).

We have seen that within the framework of macroscopic QED, Casimir forces on magnetodielectric bodies can be expressed in terms of the respective Green
tensor of the Maxwell equations for the body-assisted electromagnetic field. Hence, the main problem to be solved in practice is the determination of the Green tensors for the specific systems of interest. Since closed formulas for Green tensors are only available for highly symmetric systems (see, e.g., Ref. [461]), approximative methods are required. For example, one can start from an appropriately chosen Green tensor as zeroth-order approximation to the exact one and perform a Born expansion of the exact Green tensor by iteratively solving the corresponding Dyson-type equation. In particular, iteratively solving Eq. (141) yields the Born series

$$G(r, r', \omega) = \mathcal{C}(r, r', \omega) + \sum_{k=1}^{\infty} \left( \dfrac{\omega}{c} \right)^{2k} \left[ \prod_{j=1}^{k} \int_{V} d^3 s_j \chi(s_j, \omega) \right] \times \mathcal{C}(r, s_1, \omega) \cdot \mathcal{C}(s_1, s_2, \omega) \cdots \mathcal{C}(s_k, r', \omega). \quad (149)$$

3.2.1 Weakly polarizable bodies, micro-objects, and atoms

The very general force formulas (146) and (147), which follow from macroscopic QED without involved microscopic considerations, do not only apply to dielectric macro-objects but also to micro-objects. Moreover they also allow for studying the limiting case of individual atoms and determining in this way even the dispersion forces with which bodies act on atoms and atoms act on each other in the presence of bodies. To see this, recall that dielectric bodies may be typically thought of as consisting of distinguishable (electrically neutral but polarizable) micro-constituents (again briefly referred to as atoms), so that the Clausius–Mossotti relation [440,465]

$$\chi(r, \omega) = \varepsilon_0^{-1} \eta(r) \alpha(\omega)[1 - \eta(r)\alpha(\omega)/(3\varepsilon_0)]^{-1}$$

$$= \varepsilon_0^{-1} \eta(r) \alpha(\omega) [1 + \chi(r, \omega)/3] \quad (150)$$

may be assumed to be valid, where $\alpha(\omega)$ is the atomic polarizability and $\eta(r)$ their number density.\(^{19}\) Let $V_1$ be the volume of an isolated dielectric body of susceptibility $\chi(r, \omega)$. The Born series (149) and the Clausius–Mossotti relation (150) imply that when the body is sufficiently small and/or weakly polarizable, then the force, as given by Eq. (147), is essentially determined by the leading-order term proportional to $\chi(r, \omega) \approx \varepsilon_0^{-1} \eta(r) \alpha(\omega)$, so that Eq. (147) approximates to\(^{20}\)

$$F = -\frac{\hbar \mu_0}{2\pi} \int_{0}^{\infty} d\xi \xi^2 \int_{V_1} d^3 r \eta(r) \alpha(i\xi) \nabla \text{Tr} \mathcal{C}^{(1)}(r, r, i\xi). \quad (151)$$

\(^{19}\)Note that Eq. (150) is consistent with the requirement that both $\alpha(\omega)$ and $\chi(r, \omega)$ be Fourier transforms of response functions iff $\eta(r)\alpha(0)/(3\varepsilon_0) < 1$.

\(^{20}\)For a small and/or weakly polarizable body that is an inner part of a larger body, see Refs. [432,460,466].
where, according to the decomposition

\[
\mathcal{G}(\mathbf{r}, \mathbf{r}', \omega) = \mathcal{G}^{(0)}(\mathbf{r}, \mathbf{r}', \omega) + \mathcal{G}^{(1)}(\mathbf{r}, \mathbf{r}', \omega) \quad (\mathbf{r} \in V) \tag{152}
\]

[cf. Eq. (125)], \( \mathcal{G}^{(1)}(\mathbf{r}, \mathbf{r}', \omega) \) is simply the scattering part of the Green tensor \( \mathcal{G}(\mathbf{r}, \mathbf{r}', \omega) \) of the system without the dielectric body under consideration.

It can be easily seen that Eq. (151) may be rewritten as

\[
\mathbf{F} = \int_{V_1} d^3\mathbf{r} \eta(\mathbf{r}) \mathbf{F}(\mathbf{r}), \tag{153}
\]

where

\[
\mathbf{F}(\mathbf{r}) = -\nabla U(\mathbf{r}), \tag{154}
\]

with

\[
U(\mathbf{r}) = \frac{\hbar \mu_0}{2\pi} \int_0^\infty d\xi \xi^2 \alpha(i\xi) \text{Tr} \mathcal{G}^{(1)}(\mathbf{r}, \mathbf{r}, i\xi) \tag{155}
\]

being nothing but the van der Waals potential of a single ground-state atom of polarizability \( \alpha(\omega) \) at position \( \mathbf{r} \) in the presence of arbitrary magnetodielectric bodies (Sec. 4). Note that in the limiting case when \( V_1 \to 0 \) and \( \eta \to \infty \) but \( \eta V_1 = 1 \), such that \( V_1 \) covers a single atom at position \( \mathbf{r}_A \), then \( \mathbf{F} \) reduces to \( \mathbf{F}(\mathbf{r}_A) \)—the force acting on a single atom.

Equation (153) reveals that the force acting on a weakly polarizable dielectric body is the sum of the forces acting on all body atoms due to their interaction with other (magnetodielectric) bodies giving rise to the Green tensor \( \mathcal{G}(\mathbf{r}, \mathbf{r}', \omega) \). Let us consider in more detail the interaction of the weakly polarizable body with a second isolated dielectric body of volume \( V'_1 \), which is also weakly polarizable \( [\chi'(\mathbf{r}, \omega) \approx \varepsilon_0^{-1} \eta'(\mathbf{r}) \alpha'(\omega)] \). Denoting the Green tensor associated with all remaining bodies except for the two under consideration by \( \mathcal{G}(\mathbf{r}, \mathbf{r}', \omega) \), expanding \( \mathcal{G}(\mathbf{r}, \mathbf{r}', \omega) \), by starting from \( \mathcal{G}(\mathbf{r}, \mathbf{r}', \omega) \) in the Born series [i.e., using Eq. (149) with \( \mathcal{G} \mapsto \mathcal{G}, \mathcal{G} \mapsto \mathcal{G}, \) and \( V \mapsto V'_1 \)], and again omitting terms of higher than linear order in the susceptibility, Eq. (151) leads to

\[
\mathbf{F} = \int_{V_1} d^3\mathbf{r} \eta(\mathbf{r}) \int_{V'_1} d^3\mathbf{r}' \eta'(\mathbf{r}) \mathbf{F}(\mathbf{r}, \mathbf{r}'), \tag{156}
\]

where

\[
\mathbf{F}(\mathbf{r}, \mathbf{r}') = -\nabla U(\mathbf{r}, \mathbf{r}') \tag{157}
\]

is the force with which an atom of polarizability \( \alpha'(\omega) \) at position \( \mathbf{r}' \) acts on an atom of polarizability \( \alpha(\omega) \) at position \( \mathbf{r} \), with \( [446,467] \)

\[
U(\mathbf{r}, \mathbf{r}') = -\frac{\hbar \mu_0^2}{2\pi} \int_0^\infty d\xi \xi^4 \alpha(i\xi) \alpha'(i\xi) \text{Tr} \left[ \mathcal{G}(\mathbf{r}, \mathbf{r}, i\xi) \cdot \mathcal{G}(\mathbf{r}', \mathbf{r}, i\xi) \right] \tag{158}
\]

being the associated two-atom van der Waals potential. From Eq. (156) we see that the Casimir force between weakly polarizable dielectric bodies is the sum of all two-atom van der Waals forces between the body atoms—a result,
which was already obtained by Lifshitz for specific geometries [354]. Equation (156) clearly shows that the Casimir force is a volume force and not a surface force as could be suggested on the basis of the Minkowski stress tensor.

The force between a polarizable atom and a magnetizable one can be obtained in a similar way [468]. For this purpose, we consider the interaction of polarizable atoms contained in the first, weakly polarizable body (volume $V_1$) with a second, weakly magnetizable body of volume $V_2$ and magnetic susceptibility $\zeta(r, \omega) = \mu(r, \omega) - 1 = \mu_0 \eta_1(r) \beta(\omega)$. Here, $\beta(\omega)$ denotes the magnetizability of the atoms contained in $V_2$. We again expand the Green tensor $\mathbf{G}(r, r', \omega)$ associated with all the bodies except for the first one by starting from the Green tensor $\mathbf{G}(r, r', \omega)$ (associated with all bodies except for the two under consideration), where retaining only the linear order in $\zeta(r, \omega)$ yields

$$\mathbf{G}(r, r', \omega) = \mathbf{G}(r, r', \omega) - \int_{V_1} d^3 s \, \zeta(s, \omega) \left[ \mathbf{G}(r, s, \omega) \times \mathbf{\nabla}_s \right] \cdot \mathbf{\nabla}_s \times \mathbf{G}(s, r', \omega).$$

Upon substitution of Eq. (159), the force on the first body (151) can again be written as a sum over two-atom forces, Eqs. (156) and (157), where the potential of a polarizable atom interacting with a magnetizable one reads [468]

$$U(r, r') = -\frac{\hbar \mu_0^2}{2\pi} \int_0^\infty d\xi \, \xi^2 \alpha(i\xi) \beta'(i\xi) \times \text{Tr} \left\{ \left[ \mathbf{G}(r, s, i\xi) \times \mathbf{\nabla}_r \right] \cdot \mathbf{\nabla}_s \times \mathbf{G}(s, r, i\xi) \right\} \big|_{s=r'}.$$  

(160)

### 3.2.2 Many-atom van der Waals interactions

In general, not only two-atom interactions but all many-atom interactions must be taken into account to obtain exact dispersion forces involving one or more macroscopic objects, as has been demonstrated on the basis of both microscopic and macroscopic descriptions [422,423,467,469]. To illustrate this point, let us return to Eq. (155) and consider the interaction of a single atom with a dielectric body (volume $V$), whose susceptibility $\chi(r, \omega)$ is given by the Clausius–Mossotti relation (150). Recall from Sec. 3.2.1 that $\mathbf{G}(r, r', \omega)$ denotes the Green tensor of the total arrangement and $\mathbf{G}(r, r', \omega)$ is the Green tensor of all (background) bodies except for the one under consideration. Substituting the Born series (149) $[\mathbf{G} \mapsto \mathbf{\tilde{G}}]$ into Eq. (155), the atom–body potential can be written in the form

$$U(r) = \sum_{k=0}^\infty U_k(r),$$

(161)

where

$$U_0(r) = \frac{\hbar \mu_0}{2\pi} \int_0^\infty d\xi \, \xi^2 \alpha(i\xi) \text{Tr} \mathbf{\tilde{G}}^{(1)}(r, r, i\xi)$$

(162)
is the atomic potential due to the background bodies,\(^ {21}\) and \((k \geq 1)\)

\[
U_k(r) = \frac{(-1)^k \hbar \mu_0}{2 \pi c^{2k}} \int_0^\infty d\xi \, \xi^{2k+2} \alpha(i\xi) \left[ \prod_{j=1}^k \int_V d^3 s_j \chi(s_j, i\xi) \right] \\
\times \text{Tr} \left[ \mathbf{G}(r, s_1, i\xi) \cdot \mathbf{G}(s_1, s_2, i\xi) \cdots \mathbf{G}(s_k, r, i\xi) \right]
\]

(163)
is the contribution to the potential that is of \(k\)th order in the susceptibility of the dielectric body. To further treat the sum on the right-hand side of Eq. (163), we decompose the Green tensors therein into singular and regular parts according to

\[
\mathbf{G}(r, r', \omega) = \frac{1}{3} \left( \frac{c}{\omega} \right)^2 \delta(r - r') \mathbf{l} + \mathbf{G}'(r, r', \omega)
\]

(164)
and make use of the Clausius–Mossotti relation (150). A somewhat lengthy calculation then leads to the result that [467,469]

\[
U(r) = U_0(r) + \sum_{k=1}^\infty \frac{1}{k!} \left[ \prod_{j=1}^k \int d^3 s_j \eta(s_j) \right] U(r, s_1, \ldots, s_k),
\]

(165)
where

\[
U(r_1, r_2, \ldots, r_N) = \frac{(-1)^{N-1} \hbar \mu_0^N}{(1 + \delta_{2N}) \pi} \int_0^\infty d\xi \, \xi^{2N} \alpha_1(i\xi) \cdots \alpha_N(i\xi) \\
\times S \text{Tr} \left[ \mathbf{G}'(r_1, s_2, i\xi) \cdot \mathbf{G}'(r_2, r_3, i\xi) \cdots \mathbf{G}'(r_N, r_1, i\xi) \right]
\]

(166)
is the \(N\)-atom van der Waals potential in the presence of arbitrary magnetodielectric (background) bodies and hence generalizes the free-space result given in Refs. [263,262]. In Eq. (166), the symbol \(S\) introduces the symmetrization prescription

\[
S f(r_1, r_2, \ldots, r_N) = \frac{1}{(2 - \delta_{2N})N} \sum_{\Pi \in P(N)} f(r_{\Pi(1)}, r_{\Pi(2)}, \ldots, r_{\Pi(N)}),
\]

(167)
where \(P(N)\) denotes the permutation group of the numbers 1, 2, \ldots, \(N\). Note that \(\mathbf{G}'(r, r', \omega) = \mathbf{G}(r, r', \omega)\) for \(r \neq r'\). Clearly, for \(N = 2\), Eq. (166) reduces to the two-atom potential already given, Eq. (158).

4 Forces on atoms

As demonstrated in Secs. 3.2.1 and 3.2.2, forces on individual ground-state atoms in the presence of magnetodielectric bodies can be deduced from the

\(^{21}\)Note that \(U_0(r) = 0\) for free-space background, i.e., if there are no further bodies.
forces between dielectric bodies of Clausius–Mossotti type in the limiting case of the bodies being weakly polarizable. Alternatively, these forces can be derived by studying the interaction of atoms with the body-assisted electromagnetic field according to Sec. 2.2. This approach to dispersion forces on atoms allows for studying the influence of the internal atomic dynamics on the forces; in particular, excited atoms can also be considered.

4.1 Ground-state atoms

Atoms initially prepared in their ground state will remain in this state provided that the body-assisted field is also initially prepared in the ground state. In addition, the atom–field interaction in this case will involve only virtual, off-resonant transitions of the atoms and the body-assisted field. Consequently, dispersion forces on ground-state atoms can adequately be described within the framework of time-independent perturbation theory.

4.1.1 Single-atom force

Following the idea of Casimir and Polder [107], we derive the force on a single atom from the shift $\Delta E$ of the system’s ground-state energy $E$ for given center-of-mass position of the atom, which arises from the atom–field coupling. The potential $U(r_A)$ whose negative gradient gives the sought van der Waals force as being the position-dependent part of this energy shift,\(^{22}\)

\[
\Delta E = \Delta^{(0)} E + U(r_A).
\]  

(168)

It can be seen that the effective center-of-mass Hamiltonian

\[
\hat{H}_{\text{eff}} = \frac{\hat{P}_A^2}{2m_A} + U(\mathbf{r}_A)
\]  

(169)

leads to the equation of motion

\[
\mathbf{F}(\mathbf{r}_A) = m_A \ddot{\mathbf{r}}_A = -\frac{1}{\hbar^2} \{ \hat{H}_{\text{eff}}, \hat{H}_{\text{eff}}, m_A \mathbf{r}_A \} = -\nabla_A U(\mathbf{r}_A).
\]  

(170)

To calculate the energy shift for a nonmagnetic atom in leading order, we make use of the interaction Hamiltonian (109) and obtain in second-order

---

\(^{22}\)The constant part $\Delta^{(0)} E$ is a contribution to the Lamb shift in free space; for a discussion of the Lamb shift within the multipolar coupling scheme, see, e.g., Ref. [447].
perturbation theory \textsuperscript{23}
\[
\Delta E = \sum_k \sum_{\lambda,e,m} \mathcal{P} \int_0^{\infty} d\omega \int d^3r \frac{|\langle 0|\langle \{0\}| - \hat{d} \cdot \hat{E}(\mathbf{r}_A) |1_{\lambda}(\mathbf{r},\omega)|k\rangle|^2}{-\hbar(\omega_{k0} + \omega)}
\]
\[
(171)
\]
\[|1_{\lambda}(\mathbf{r},\omega) = \hat{f}^\dagger_\lambda(\mathbf{r},\omega)|\{0\}\rangle].\]
Using Eqs. (28)-(30), (33), and (34), we derive
\[
\Delta E = -\frac{\mu_0}{\pi} \sum_{\lambda} \mathcal{P} \int_0^{\infty} \frac{d\omega}{\omega_{k0} + \omega} \omega^2 d_{0k} \cdot \text{Im} G(\mathbf{r}_A,\mathbf{r}_A,\omega) \cdot d_{k0},
\]
\[
(172)
\]
where $G(\mathbf{r},\mathbf{r}',\omega)$ is the Green tensor of the body configuration considered.
By discarding the position-independent contribution $\Delta E^{(0)}$ associated with $G^{(0)}(\mathbf{r}_A,\mathbf{r}_A,\omega)$ [recall Eqs. (125) and (168)], which may be thought of as being already included in the unperturbed energy, the vdW potential can be written in the form \textsuperscript{[444,470,471]}
\[
U(\mathbf{r}_A) = \frac{\hbar \mu_0}{2\pi} \int_0^{\infty} d\xi \xi^2 \text{Tr} \left[ \alpha(i\xi) \cdot G^{(1)}(\mathbf{r}_A,\mathbf{r}_A,0) \right],
\]
\[
(173)
\]
where
\[
\alpha(\omega) = \lim_{\epsilon \to 0} \frac{2}{\hbar} \sum_k \frac{\omega_{k0} d_{0k} d_{k0}}{\omega_{k0}^2 - \omega^2 - i\omega\epsilon}
\]
\[
(174)
\]
is the ground-state polarizability of the atom. For isotropic atoms, it is given by
\[
\alpha(\omega) = \alpha(\omega) I = \lim_{\epsilon \to 0} \frac{2}{3\hbar} \sum_k \frac{|d_{0k}|^2 \omega_{k0}}{\omega_{k0}^2 - \omega^2 - i\omega\epsilon} I,
\]
\[
(175)
\]
so the potential simplifies to
\[
U(\mathbf{r}_A) = \frac{\hbar \mu_0}{2\pi} \int_0^{\infty} d\xi \xi^2 \alpha(i\xi) \text{Tr} G^{(1)}(\mathbf{r}_A,\mathbf{r}_A,0).
\]
\[
(176)
\]
The perturbative result hence agrees with what we have inferred from the force on weakly polarizable bodies and renders an explicit expression for the polarizability. Note that the scattering Green tensor $G^{(1)}$ in Eq. (176) has exactly the same meaning as $\overline{G}$ in Eq. (155). From Eq. (176) together with Eq. (175) it can be seen that the potential can be given in the equivalent form
\[
U(\mathbf{r}_A) = -\frac{\hbar \mu_0}{2\pi} \int_0^{\infty} d\omega \omega^2 \alpha(\omega) \text{Tr} \text{Im} G^{(1)}(\mathbf{r}_A,\mathbf{r}_A,\omega),
\]
\[
(177)
\]
which allows for a simple physical interpretation of the force as being due to correlation of the fluctuating electromagnetic field with the corresponding

\textsuperscript{23}In the following, we will employ the multipolar coupling scheme and drop the primes discriminating the respective atomic and field variables from the minimal coupling ones. Equation (109) can be employed, because the second term in Eq. (108) gives rise to a contribution of order $v/c$ ($v$, center-of-mass speed) \textsuperscript{[444]}, which can be neglected.
induced electric dipole of the atom plus the correlation of the fluctuating electric dipole with its induced electric field [398].

It should be pointed out that an analogous treatment based on the minimal-coupling Hamiltonian (91) leads to the formally same result [444], where of course the unperturbed eigenstates and energies occurring in the polarizability (174) are now determined by the atomic Hamiltonian (54) in place of (101). Needless to say that both results are approximations to the same Hamiltonian of the total system. Bearing in mind that the ground-state energy shift is entirely due to virtual, off-resonant transitions, it is crucial to retain the $A^2$-term in the minimal coupling scheme, which contributes to the ground-state energy shift already in first-order perturbation theory.

4.1.2 Two-atom force

The interaction potential of two polarizable ground-state atoms in the presence of magnetodielectric bodies giving rise to the Green tensor $G(r, r', \omega)$ can also be obtained by means of time-independent perturbation theory. The leading contribution is now of fourth order in the atom–field interaction, and a lengthy calculation yields [446,467]

$$U(r_A, r_B) = -\frac{\hbar}{2\pi} \int_0^\infty d\xi \, \xi^4 \times \text{Tr}[\alpha_A(i\xi) \cdot G(r_A, r_B, i\xi) \cdot \alpha_B(i\xi) \cdot G(r_B, r_A, i\xi)].$$

(178)

For isotropic atoms, Eq. (179) reduces to

$$U(r_A, r_B) = -\frac{\hbar}{2\pi} \int_0^\infty d\xi \, \xi^4 \alpha_A(i\xi) \alpha_B(i\xi) \times \text{Tr}[G(r_A, r_B, i\xi) \cdot G(r_B, r_A, i\xi)]$$

(179)

and agrees with Eq. (158) $[G'(r_1, r_2, \omega) \mapsto G(r_A, r_B, \omega)$ for $r_1 \neq r_2]$. The total force acting on atom $A$ ($B$) can be obtained by supplementing the single-atom force $F(r_{A(B)})$ with the two-atom force

$$F(r_{A(B)}, r_{B(A)}) = -\nabla_{A(B)} U(r_A, r_B),$$

(180)

where in general $F(r_A, r_B) \neq -F(r_B, r_A)$, due to the presence of the bodies.

In the special case of two atoms in free space, the single-atom force identically vanishes, and the two-atom potential (179) can be calculated by using the free-space Green tensor $G(r, r', \omega) = G_{\text{free}}(r, r', \omega)$ (App. A), leading to

$$U(r_A, r_B) = -\frac{\hbar}{32\pi^3 \varepsilon_0} \int_0^\infty d\xi \, \alpha_A(i\xi) \alpha_B(i\xi) g(\xi r/c),$$

(181)
where
\[ g(x) = 2e^{-2x} \left( 3 + 6x + 5x^2 + 2x^3 + x^4 \right) \]  

\( (r = |\mathbf{r}_A - \mathbf{r}_B|) \), in agreement with the well-known result of Casimir and Polder [107]. From Eq. (181) together with Eq. (182) it is not difficult to see that the interaction between two polarizable atoms is always attractive.

In the retarded limit, where \( r \gg c/\omega_{\text{min}} \) (\( \omega_{\text{min}} \) denoting the minimum of the relevant resonance frequencies of atoms \( A \) and \( B \)), the factor \( g(\xi r/c) \) effectively limits the \( \xi \) integral in Eq. (181) to a range where \( \alpha_{A(B)}(i \xi) \approx \alpha_{A(B)}(0) \), so the potential approaches
\[
U(\mathbf{r}_A, \mathbf{r}_B) = -\frac{23\hbar c \alpha_A(0) \alpha_B(0)}{64\pi^3 \varepsilon_0^2 r^4}.
\]

In the nonretarded limit, where \( r \ll c/\omega_{\text{max}} \) (\( \omega_{\text{max}} \) denoting the maximum of the relevant resonance frequencies of atoms \( A \) and \( B \)), the integral is limited by the factors \( \alpha_{A(B)}(i \xi) \) to a range where \( g(i \xi) \approx g(0) = 6 \), leading to the London potential [164]
\[
U(\mathbf{r}_A, \mathbf{r}_B) = -\frac{3\hbar}{16\pi^3 \varepsilon_0^2 r^6} \int_0^\infty d\xi \alpha_A(i \xi) \alpha_B(i \xi).
\]

It is illustrative to compare the potential between two polarizable atoms with the potential between a polarizable atom \( A \) of polarizability \( \alpha_A(\omega) \) and a magnetizable atom \( B \) of magnetizability \( \beta_B(\omega) \), which according to Eq. (160) is given by
\[
U(\mathbf{r}_A, \mathbf{r}_B) = -\frac{\hbar \mu_0^2}{2\pi} \int_0^\infty d\xi \xi^2 \alpha_A(i \xi) \beta_B(i \xi)
\]
\[
\times \text{Tr} \left\{ \left[ \mathcal{G}(\mathbf{r}_A, \mathbf{r}, i \xi) \times \nabla_r \right] \cdot \nabla_r \times \mathcal{G}(\mathbf{r}, \mathbf{r}_A, i \xi) \right\}_{r=r_B}.
\]

When the two atoms are in free space, so that \( \mathcal{G}(\mathbf{r}, \mathbf{r}', \omega) = \mathcal{G}_{\text{free}}(\mathbf{r}, \mathbf{r}', \omega) \), then Eq. (185) reads
\[
U(\mathbf{r}_A, \mathbf{r}_B) = -\frac{\hbar \mu_0^2}{32\pi^3 r^4} \int_0^\infty d\xi \xi^2 \alpha_A(i \xi) \beta_B(i \xi) h(\xi r/c),
\]

where
\[
h(x) = 2e^{-2x} \left( 1 + 2x + x^2 \right),
\]

which is in agreement with the result found by means of perturbation theory [268,269]. In contrast to the attractive interaction between two polarizable atoms, the interaction between a polarizable and a magnetizable atom is always repulsive, as can be easily seen from Eq. (186) together with Eq. (187).
Equation (186) approaches

\[ U(r_A, r_B) = \frac{7\hbar\mu_0 c\alpha_A(0)\beta_B(0)}{64\pi^3\varepsilon_0 r^7} \]  \hspace{1cm} (188)

in the retarded limit and

\[ U(r_A, r_B) = \frac{\hbar\mu_0}{16\pi^3\varepsilon_0 r^4} \int_0^\infty d\xi \left( \frac{\xi}{c} \right)^2 \alpha_A(i\xi)\beta_B(i\xi) \]  \hspace{1cm} (189)

in the nonretarded limit. Comparing Eqs. (183) and (188), we see that in the retarded limit the force between two polarizable atoms and that between a polarizable and a magnetizable atom follow the same 1/r^8 power law, with the strength being weaker in the latter case by a factor 7/23. Comparison of Eqs. (184) and (189) shows that in the nonretarded limit the force between a polarizable and a magnetizable atom (∼1/r^5) is more weakly diverging than that between two polarizable atoms (∼1/r^7).

4.1.3 Atom in a planar structure

The general expression for the force on a single ground-state atom in the presence of bodies derived in Sec. 4.1.1 on the basis of macroscopic QED—or a similar result found in a related treatment [472,473,474]—has been applied to a variety of bodies, such as dielectric [475] or magnetodielectric spheres [467], magnetodielectric rings [469], or cylindrical bodies, e.g., carbon nanotubes [472,473,474]. Here, we consider a single polarizable atom placed in a free-space region between two planar walls, as given by Eqs. (130) and (131) with ε(ω) ≡ μ(ω) ≡ 1. Inserting the Green tensor for this magnetodielectric structure (App. A) into Eq. (176) leads to the single-atom potential [470,476]

\[ U(z_A) = \frac{\hbar\mu_0}{8\pi^2} \int_0^\infty d\xi \xi^2 \alpha(i\xi) \int_0^\infty dq \frac{q}{b} \left\{ e^{-2b\xi A} \left[ \frac{r_{s-}}{D_s} - \left( 1 + 2 \frac{q^2c^2}{\xi^2} \right) \frac{r_{p-}}{D_p} \right] 
\[ + e^{-2b(d-z_A)} \left[ \frac{r_{s+}}{D_s} - \left( 1 + 2 \frac{q^2c^2}{\xi^2} \right) \frac{r_{p+}}{D_p} \right] \right\}, \]  \hspace{1cm} (190)

where \( z_A \) is the separation of the atom from the left wall, \( d \) is the separation of the two walls, \( b \) and \( D_\sigma \) are given by Eqs. (135) and (136), respectively, with \( n(i\xi) \equiv 1 \), and \( r_{s\pm} = r_{s\pm}(\xi, q) \) are again the reflection coefficients associated with the left/right walls. If the atom is placed near a single wall, say the right wall is missing, Eq. (190) reduces to \( r_\sigma \equiv r_{\sigma-} \)

\[ U(z_A) = \frac{\hbar\mu_0}{8\pi^2} \int_0^\infty d\xi \xi^2 \alpha(i\xi) \int_0^\infty dq \frac{q}{b} e^{-2b\xi A} \left[ r_s - \left( 1 + 2 \frac{q^2c^2}{\xi^2} \right) r_p \right]. \]  \hspace{1cm} (191)

46
4.1.3.1 Perfectly reflecting plate  Consider first an atom placed near an perfectly reflecting electric (i.e., perfectly conducting) plate, \( r_p = -r_s = 1 \). By changing the integration variable in Eq. (191) from \( q \) to \( b \) [Eq. (135)], the resulting integral can be performed, leading to

\[
U(z_A) = -\frac{\hbar}{16\pi^2\varepsilon_0 z_A^3} \int_0^\infty d\xi \alpha(i\xi) e^{-2\xi z_A/c} \left[ 1 + 2 \left( \frac{\xi z_A}{c} \right) + 2 \left( \frac{\xi z_A}{c} \right)^2 \right], \tag{192}
\]

in agreement with the famous result found by Casimir and Polder [107]. In the retarded limit, \( z_A \gg c/\omega_{\text{min}} \), the exponential factor effectively limits the \( u \) integral to a range where \( \alpha(i\xi) \simeq \alpha(0) \), so the potential approaches

\[
U(z_A) = -\frac{3hc\alpha(0)}{32\pi^2\varepsilon_0 z_A^4}. \tag{193}
\]

In the nonretarded limit, \( z_A \ll c/\omega_{\text{max}} \), the factor \( \alpha(i\xi) \) restricts the integration to regions where \( \xi z_A/c \simeq 0 \), leading to the Lennard-Jones potential [177]

\[
U(z_A) = -\frac{1}{48\pi\varepsilon_0 z_A^3} \sum_k |d_{ok}|^2 = -\frac{\langle 0|\hat{d}^2|0 \rangle}{48\pi\varepsilon_0 z_A^3}, \tag{194}
\]

recall Eq. (175).

In contrast, the potential (191) of an atom in front of an infinitely permeable plate, \( r_p = -r_s = -1 \), is repulsive,

\[
U(z_A) = \frac{\hbar}{16\pi^2\varepsilon_0 z_A^3} \int_0^\infty d\xi \alpha(i\xi)e^{-2\xi z_A/c} \left[ 1 + 2 \left( \frac{\xi z_A}{c} \right) + 2 \left( \frac{\xi z_A}{c} \right)^2 \right]. \tag{195}
\]

It approaches

\[
U(z_A) = \frac{3hc\alpha(0)}{32\pi^2\varepsilon_0 z_A^4} \tag{196}
\]

in the retarded limit (also see Ref. [308]) and

\[
U(z_A) = \frac{\langle 0|\hat{d}^2|0 \rangle}{48\pi\varepsilon_0 z_A^3} \tag{197}
\]

in the nonretarded limit.

The different signs of the nonretarded potentials (194) and (197) in the cases of a perfectly reflecting electric and a perfectly reflecting magnetic plate, respectively, can be understood from an image-dipole model [177]. The nonretarded potential can be regarded as being due to the Coulomb interaction of an electric dipole \( \hat{d} = (\hat{d}_x, \hat{d}_y, \hat{d}_z) \) situated at distance \( z_A \) from the plate with its image \( \hat{d}' = (-\hat{d}_x, -\hat{d}_y, \hat{d}_z) \) in the plate [Fig 1(a)]. The average interaction energy of
Fig. 1. Image dipole construction for an (a) electric (b) magnetic dipole in front of a perfectly reflecting electric plate.

the dipole and its image hence reads \cite{440} \cite{24}

\[
U(z_A) = \frac{1}{2} \frac{\langle 0 | \hat{d} \cdot \hat{d'} - 3 \hat{d}_x \hat{d'}_x | 0 \rangle}{4\pi \varepsilon_0 (2z_A)^3} = -\frac{\langle 0 | \hat{d}^2 + \hat{d'}^2_x | 0 \rangle}{64\pi \varepsilon_0 z_A^3} = -\frac{\langle 0 | \hat{d}^2 | 0 \rangle}{48\pi \varepsilon_0 z_A^3},
\]

(198)

in agreement with Eq. (194), where we have used \(\langle 0 | \hat{d}^2 | 0 \rangle = \langle 0 | \hat{d}_x^2 | 0 \rangle = \langle 0 | \hat{d}_z^2 | 0 \rangle = (1/3) \langle 0 | \hat{d}^2 | 0 \rangle\).

The interaction of a polarizable atom with an infinitely permeable plate is equivalent to the interaction of a magnetizable atom with a perfectly reflecting dielectric plate by virtue of the duality of electric and magnetic fields. We hence consider a magnetic dipole \(\hat{m} = (\hat{m}_x, \hat{m}_x, \hat{m}_z)\) in front of a perfectly reflecting dielectric plate. Since a magnetic dipole behaves like a pseudo-vector under reflection, its image is given by \(\hat{m}' = (\hat{m}_x, \hat{m}_x, -\hat{m}_z)\) [Fig 1(b)]. The interaction energy of the magnetic dipole and its image reads

\[
U(z_A) = \frac{1}{2} \frac{\langle 0 | \hat{m} \cdot \hat{m'} - 3 \hat{m}_x \hat{m'}_x | 0 \rangle}{4\pi \varepsilon_0 (2z_A)^3} = \frac{\langle 0 | \hat{m}^2 | 0 \rangle}{48\pi \varepsilon_0 z_A^3},
\]

(199)

which by means of a duality transformation is equivalent to Eq. (197). The different signs of the potentials (194) and (197) can thus be understood from the different reflection behavior of electric and magnetic dipoles.

\subsection{4.1.3.2 Magnetodielectric half space}

To be more realistic, let us next consider an atom in front of a semi-infinite half space of given \(\varepsilon(\omega)\) and \(\mu(\omega)\). Upon substitution of the Fresnel reflection coefficients (A.10), Eq. (191) takes

\footnote{The factor 1/2 in Eq. (198) accounts for the fact that the second dipole is induced by the first one.}
the form [470,476]

\[ U(z_A) = \frac{\hbar \mu_0}{8\pi^2} \int_0^\infty d\xi \xi^2 \alpha(i\xi) \int_0^\infty dq \frac{q}{b} e^{-2b\xi z_A} \left[ \frac{\mu(i\xi)b - b_1}{\mu(i\xi)b + b_1} \right. \\
\left. - \left(1 + 2\frac{q^2c^2}{\xi^2}\right) \frac{\varepsilon(i\xi)b - b_1}{\varepsilon(i\xi)b + b_1} \right] \] (200)

with \( b_1 \equiv b_1^- \) defined as in Eq. (A.9), in agreement with the result based on linear response theory [403].

One can show that in the retarded limit \( z_A \gg c/\omega_{\text{min}} \) (with \( \omega_{\text{min}} \) being the minimum of all relevant atom and medium resonance frequencies) the potential takes the asymptotic form [470,476]

\[ U(z_A) = -\frac{3\hbar c\alpha(0)}{64\pi^2 \varepsilon_0 z_A^4} \int_1^\infty dv \left[ \left( \frac{2}{v^2} - \frac{1}{v^4} \right) \frac{\varepsilon(0)v - \sqrt{\varepsilon(0)\mu(0) - 1 + v^2}}{\varepsilon(0)v + \sqrt{\varepsilon(0)\mu(0) - 1 + v^2}} \\
- \frac{1}{v^4} \frac{\mu(0)v - \sqrt{\varepsilon(0)\mu(0) - 1 + v^2}}{\mu(0)v + \sqrt{\varepsilon(0)\mu(0) - 1 + v^2}} \right]. \] (201)

which can be attractive or repulsive, depending on the strengths of the competing magnetic and electric properties of the half space. Figure 2 shows the division line between attractive and repulsive potentials in the \( \varepsilon(0)\mu(0) \)-plane. In particular, repulsion occurs iff \( \mu(0) - 1 > 3.29[\varepsilon(0) - 1] \) or \( \mu(0) > 5.11\varepsilon(0) \) for weak and strong magnetodielectric properties, respectively.
Fig. 3. The potential of a ground-state two-level atom in front of a magnetodielectric half space, Eq. (200), is shown as a function of the distance between the atom and the half space for different values of $\mu(0)$ ($\omega_{pe}/\omega_{10} = 0.75$, $\omega_{Te}/\omega_{10} = 1.03$, $\omega_{Tm}/\omega_{10} = 1$, $\gamma_{e}/\omega_{10} = \gamma_{m}/\omega_{10} = 0.001$).

In the nonretarded limit, $n(0)z_{A} \ll c/\omega_{\text{max}}$ [where $\omega_{\text{max}}$ is maximum of all relevant atom and medium resonance frequencies; $n(0) = \sqrt{\varepsilon(0)\mu(0)}$], the situation is more complex, because electric and magnetic medium properties give rise to potentials with different asymptotic power laws. In particular, the potential approaches

$$U(z_{A}) = -\frac{\hbar}{16\pi^{2}\varepsilon_{0}z_{A}^{3}} \int_{0}^{\infty} d\xi \frac{\alpha(i\xi)}{\varepsilon(i\xi) + 1} \varepsilon(i\xi) - 1$$

in the case of a purely polazible half space, and

$$U(z_{A}) = \frac{\hbar}{32\pi^{2}\varepsilon_{0}z_{A}^{3}} \int_{0}^{\infty} d\xi \left(\frac{\xi}{c}\right)^{2} \frac{\alpha(i\xi)}{\mu(i\xi) + 1} \frac{[\mu(i\xi) - 1][\mu(i\xi) + 3]}{\mu(i\xi) + 1}$$

in the case of a purely magnetizable one [470,476]. Thus for a genuinely magnetodielectric half space the attractive $1/z_{A}^{3}$ potential associated with the polarizability of the half space will always dominate the repulsive $1/z_{A}$ potential related to its magnetizability. It should be noted that the nonretarded limit is in general incompatible with the limit of perfect reflectivity considered in Sec. 4.1.3.1. So, Eq. (203) does not approach Eq. (197) as $\mu(i\xi)$ tends to infinity. On the contrary, Eq. (202) converges to Eq. (194) as $\varepsilon(i\xi)$ tends to
Combining the observations from the retarded and nonretarded limits, we may thus expect a potential barrier, provided that the permeability of the half space is sufficiently large \[470,476\]. This is illustrated in Fig. 3, where the potential of a two-level atom as a function of its distance from the half space is shown for various values of the (static) permeability. In the numerical computation of the integrals in Eq. (200), the permittivity and permeability of the half space have been assumed to be of Drude–Lorentz type,

\[
\varepsilon(\omega) = 1 + \frac{\omega_p^2}{\omega_c^2 - \omega^2 - i\gamma_e}, \quad \mu(\omega) = 1 + \frac{\omega_m^2}{\omega_m^2 - \omega^2 - i\gamma_m},
\]

From the figure it is seen that with increasing value of \(\mu(0)\) a potential barrier begins to form at intermediate distances, as expected. It is shifted to smaller distances and increases in height as the value of \(\mu(0)\) is further increased.

### 4.1.3.3 Plate of finite thickness

Consider now an atom in front of a magnetodielectric plate of finite thickness \(d\). Evaluating the relevant reflection coefficients (A.7) and (A.8) \(d \equiv d^-\), one finds that Eq. (191) takes the form \[470,476\]

\[
U(z_A) = \frac{\hbar \mu_0}{8\pi^2} \int_0^\infty d\xi \xi^2 \alpha(i\xi) \int_0^\infty dq \frac{q}{b} e^{-2b\xi} \left\{ \frac{[\mu^2(i\xi)b^2 - b_1^2] \tanh(b_1d)}{2\mu i\xi b_1 + [\mu^2(i\xi)b^2 + b_1^2] \tanh(b_1d)} - \left(1 + 2 \frac{q^2 \xi^2}{\xi^2} \right) \frac{[\varepsilon^2(i\xi)b^2 - b_1^2] \tanh(b_1d)}{2\varepsilon i\xi b_1 + [\varepsilon^2(i\xi)b^2 + b_1^2] \tanh(b_1d)} \right\},
\]

which reduces to the result in Ref. [309] in the special case of a nonabsorbing dielectric plate. For an asymptotically thick plate, \(d \gg z_A\), the exponential factor restricts the integral in Eq. (205) to a region where \(b_1d \sim d/(2z_A) \gg 1\). One may hence make the approximation \(\tanh(b_1d) \approx 1\), leading back to Eq. (200), which demonstrates that the semi-infinite half space is a good model provided that \(d \gg z_A\).

On the contrary, in the limit of an asymptotically thin plate, \(n(0)d \ll z_A\), the approximation \(b_1d \ll 1\) results in \[470,476\]

\[
U(z_A) = \frac{\hbar \mu_0 d}{8\pi^2} \int_0^\infty d\xi \xi^2 \alpha(i\xi) \int_0^\infty dq \frac{q}{b} e^{-2b\xi} \left[ \frac{\mu^2(i\xi)b^2 - b_1^2}{2\mu i\xi b} \right] - \left(1 + 2 \frac{q^2 \xi^2}{\xi^2} \right) \frac{[\varepsilon^2(i\xi)b^2 - b_1^2]}{2\varepsilon i\xi b},
\]

\(51\)
Fig. 4. The potential of a ground-state two-level atom in front of a magnetodielectric plate, Eq. (205), is shown as a function of the atom–plate separation for different values of the plate thickness $d$ [$\mu(0) = 5$, all other parameters are the same as in Fig. 2].

which in the retarded limit approaches

$$ U(z_A) = -\frac{h\alpha(0)d}{160\pi^2\varepsilon_0 z_A^3} \left[ \frac{14\varepsilon^2(0) - 9}{\varepsilon(0)} - \frac{6\mu^2(0) - 1}{\mu(0)} \right]. \quad (207) $$

In the nonretarded limit one can again distinguish between a purely polarizable plate and a pure magnetizable plate. Equation (206) approaches

$$ U(z_A) = -\frac{3hd}{64\pi^2\varepsilon_0 z_A^4} \int_0^\infty d\xi \alpha(i\xi) \frac{\varepsilon^2(i\xi) - 1}{\varepsilon(i\xi)}, \quad (208) $$
in the former case and

$$ U(z_A) = \frac{hd}{64\pi^2\varepsilon_0 z_A^2} \int_0^\infty d\xi \left( \frac{\xi}{c} \right)^2 \alpha(i\xi) \frac{[\mu(i\xi) - 1][3\mu(i\xi) + 1]}{\mu(i\xi)} \quad (209) $$
in the latter case. Comparing Eqs. (207)–(209) with Eqs. (201)–(203), we see that the power laws change from $z_A^{-\lambda}$ to $z_A^{-(\lambda+1)}$ when the plate thickness changes from being infinitely large to being infinitely small.
If the permeability is sufficiently big, a magnetodielectric plate of finite thickness also features a potential wall [470,476], as illustrated in Fig. 4 for a two-level atom, with the permittivity and permeability of the plate being again given by Eq. (204). It is seen that for a thin plate the barrier is very low. It raises with increasing thickness of the plate, reaches a maximal height for some intermediate thickness and then lowers slowly towards the asymptotic half space value as the thickness is further increased.

4.1.3.4 Planar cavity When an atom is placed between two magnetodielectric plates, then the competing effects of attractive and repulsive interaction with the two plates can result in the formation of a trapping potential [470,476]. For simplicity, let us consider two identical half space of permittivity \( \varepsilon(\omega) \) and permeability \( \mu(\omega) \), which are separated by a distance \( d \). Substitution of the Fresnel reflection coefficients (A.10) into Eq. (190) yields the potential of an atom placed within a cavity bounded by the half spaces:

\[
U(z) = \frac{\hbar \mu_0}{8\pi^2} \int_0^\infty d\xi \xi^2 \alpha(i\xi) \int_0^\infty dq \frac{q}{b} \left[ e^{-2b_dz_A} + e^{-2b(d-z_A)} \right] \left[ \frac{1}{D_s} \frac{\mu(i\xi)b - b_1}{\mu(i\xi)b + b_1} \right] - \left( 1 + 2\phi^2 \right) \frac{1}{D_p} \frac{\varepsilon(i\xi)b - b_1}{\varepsilon(i\xi)b + b_1}, \tag{210}
\]

As expected, this potential is in general not the sum of the potentials associated with the left and right plates separately, as a comparison of Eq. (210) with Eq. (200) shows. Clearly, the difference is due to the effect of multiple reflection between the two plates, which gives rise to the denominators \( D_{\sigma} \),

\[
\frac{1}{D_{\sigma}} = \sum_{n=0}^{\infty} \left( r_{\sigma} e^{-bd} r_{\sigma+} e^{-bd} \right)^n, \tag{211}
\]

recall Eq. (136).

The formation of a potential well is illustrated in Fig. 5, where the potentials of an atom placed between purely polarizable and purely magnetizable plates is also shown. It is seen that the attractive (repulsive) potentials associated with each of two purely polarizable (magnetizable) plates combine to an infinite potential wall (well) at the center of the cavity, while a potential well of finite depth can be realized within the cavity in the case of two genuinely magnetodielectric plates of sufficiently large permeability.

4.1.4 Asymptotic power laws

As we have seen, the dispersive interaction of polarizable/magnetizable objects in their ground states can often be given in terms of simple asymptotic power
laws in the retarded and nonretarded limits. Typical examples are given in Tab. 1, where the asymptotic power laws for the dispersion force on an atom interacting with another atom [Eqs. (183), (184), (188), and (189)], a small sphere [467], thin ring [469], a thin plate [Eqs. (207)–(209)], and a semi-infinite half space [Eqs. (201)–(203)], and for the force per unit area between two half spaces are shown [366,464].

Comparing the dispersion forces between objects of different shapes and sizes, it is seen that the signs are always the same, while the leading inverse powers are the same or changed by some global power when moving from one row of the table to another. This can be understood by assuming that the leading inverse power is determined by the contribution to the force which results from the two-atom interaction [row (a)] by pairwise summation. Obviously, integration of two-atom forces over the (finite) volumes of a small sphere (b) or a thin ring (c) does not change the respective power law, while integration over an infinite volume lowers the leading inverse power according to the number of infinite dimensions. So, the leading inverse powers are lowered

---

Fig. 5. The potential of a ground-state two-level atom placed between two (a) magnetodielectric (all parameters as in Fig. 3), (b) purely polarizable \( \mu(\omega) \equiv 1 \), other parameters as in (a)], and (c) purely magnetizable \( \varepsilon(\omega) \equiv 1 \), other parameters as in (a)] half spaces of separation \( d = 15c/\omega_{10} \), Eq. (210), is shown as a function of the position of the atom.
Table 1  
Asymptotic power laws for the forces between (a) two atoms, (b) an atom and a small sphere, (c) an atom and a thin ring, (d) an atom and a thin plate, (e) an atom and a half space, and (f) for the force per unit area between two half spaces. In the table heading, p stands for a polarizable object and m for a magnetizable one. The signs + and − denote repulsive and attractive forces, respectively.

by two and three for the interaction of an atom with a thin plate of infinite lateral extension (d) and a half space (e), respectively. The power laws for the force between two half spaces (f) can then be obtained from the atom-half-space force (e) by integrating over the three infinite dimensions, where integration over z lowers the leading inverse powers by one while the trivial integrations over x and y yield an infinite force, i.e., a finite force per unit area. It follows from the table that many-atom interactions do not change the leading power laws resulting from the summation of pairwise interactions, but only modify the proportionality factors.

All dispersion forces in Tab. 1 are seen to be attractive for two polarizable objects and repulsive for a polarizable object interacting with a magnetizable one. It can further be noted that in the retarded limit the forces decrease more rapidly with increasing distance than might be suggested from considering only the nonretarded limit. Finally, the table shows that the retarded dispersion
forces between polarizable/polarizable and polarizable/magnetizable objects follow the same power laws, while in the nonretarded limit the forces between polarizable and magnetizable objects are weaker than those between polarizable objects by two powers in the object separation. This can be understood by regarding the forces as being due to the electromagnetic field created by the first object interacting with the second. While the electric and magnetic far fields created by an oscillating electric dipole display the same distance dependence, the electric near field (which can interact with a second polarizable object) is stronger than the magnetic near field (which interacts with a second magnetizable object) by one power in the object separation (giving rise to a difference of two powers in second-order perturbation theory).

4.2 Excited atoms

In a first attempt, dispersion forces on atoms in excited energy eigenstates can also be derived from perturbative energy shifts. A straightforward generalization of the calculation outlined in Sec. 4.1.1 to an atom prepared in an arbitrary energy eigenstate $|m\rangle$ yields the potential [444,470,471]

$$U_m(r_A) = U_{m}^{\alpha\alpha}(r_A) + U_{m}^{\pi\pi}(r_A),$$

(212)

where

$$U_{m}^{\alpha\alpha}(r_A) = \frac{\hbar \mu_0}{2\pi} \int_0^\infty d\xi \xi^2 \text{Tr} \left[ \alpha_m(i\xi) \cdot G^{(1)}(r_A, r_A, i\xi) \right]$$

(213)

and

$$U_{m}^{\pi\pi}(r_A) = -\mu_0 \sum_k \Theta(\omega_{mk})\omega_{mk}^2 d_{mk} \cdot \text{Re} G^{(1)}(r_A, r_A, \omega_{mk}) \cdot d_{km}$$

(214)

$[\Theta(z), \text{unit step function}]$ are the off-resonant and resonant contributions to the potential, and

$$\alpha_m(\omega) = \lim_{\varepsilon \to 0} \frac{1}{\hbar} \sum_k \left[ \frac{d_{mk}d_{km}}{\omega_{km} - \omega - i\varepsilon} + \frac{d_{km}d_{mk}}{\omega_{km} + \omega + i\varepsilon} \right]$$

(215)

is the atomic polarizability tensor. The potential (212)–(214) obviously reduces to the ground-state result (173) in the special case $m = 0$. Note that the resonant contribution vanishes in the ground state; it is only present for an excited atom that can undergo real transitions.

Inspection of Eqs. (212)–(215) reveals that the application of (time-independent) perturbation theory to excited atoms is problematic in several respects. First, the potential is determined by quantities that are attributed to the unperturbed atomic transitions, which do not take into account the effect of line broadening, whereas in practice finite linewidths are observed which are
known to strongly affect resonant transitions. Second, the potential and hence also the force remains constant in time, which is not very realistic for excited atoms which undergo spontaneous decay, with the allowed (dipole-)transitions being the same as those entering the potential. And third, perturbation theory does not apply to the case of strong atom–field coupling. These problems can be overcome by a dynamical approach to the calculation of forces acting on excited atoms.

4.2.1 Lorentz force approach

Instead of deriving the dispersion force from an energy shift by some means or other, we return to the origin of the force by starting from the Lorentz force acting on an atom and calculating its expectation value for a given initial state. In particular, when the electromagnetic field is initially in its ground state, then this expression yields the sought dispersion force, which is genuinely time-dependent for atoms initially prepared in excited states.

Summing the physical momenta $m_\alpha \hat{r}_\alpha$ of the particles constituting the atom [as given by Eq. (104)], one obtains for the atom as a whole

$$m_A \dot{\vec{r}}_A = \dot{\vec{p}}_A + \int d^3 r \dot{\vec{P}}_{at}(r) \times \vec{B}(r).$$

(216)

Hence the center-of-mass motion is governed by the Newton equation

$$m_A \ddot{r}_A = \vec{F}_L,$$

(217)

where, according to Eq. (216), the Lorentz force is given by

$$\vec{F}_L = \frac{i}{\hbar} \left[ \hat{H}, \dot{\vec{p}}_A \right] + \frac{d}{dt} \int d^3 r \dot{\vec{P}}_{at}(r) \times \vec{B}(r)$$

(218)

with $\dot{\vec{P}}_{at}(r)$ from Eq. (68). The first term in Eq. (218) can be further evaluated by recalling Eq. (97) and using the commutation relations (65). By making use of the identity $\nabla A \dot{\vec{P}}_{at}(r) = -\nabla \vec{P}_{at}(r)$ [recall Eq. (68)], one can show that

$$i \frac{1}{\hbar} \left[ \frac{1}{2 \varepsilon_0} \int d^3 r \dot{\vec{P}}^2_{at}(r), \dot{\vec{p}}_A \right] = \frac{1}{2 \varepsilon_0} \int d^3 r \nabla \dot{\vec{P}}^2_{at}(r) = 0,$$

(219)

and by recalling Eq. (96) and using the definitions (68) and (69), one derives

$$\frac{i}{\hbar} \left[ \sum_{\alpha} \frac{1}{2m_\alpha} \left\{ \dot{\vec{p}}_\alpha + \int d^3 r \vec{\Xi}_\alpha(r) \times \vec{B}(r) \right\}^2, \dot{\vec{p}}_A \right]$$

$$= \nabla A \left\{ \int d^3 r \left[ \vec{M}_{at}(r) + \dot{\vec{P}}_{at}(r) \times \dot{r}_A \right] \cdot \vec{B}(r) \right\},$$

(220)
Equations (219) and (220) then imply that Eq. (218) can be written as

\[
\hat{\mathbf{F}}_L = \nabla_A \left\{ \int d^3 r \, \hat{\mathbf{P}}_{at}(r) \cdot \hat{\mathbf{E}}(r) + \int d^3 r \left[ \hat{\mathbf{M}}_{at}(r) + \hat{\mathbf{P}}_{at}(r) \times \hat{\mathbf{r}}_A \right] \cdot \hat{\mathbf{B}}(r) \right\} + \frac{d}{dt} \int d^3 r \, \hat{\mathbf{P}}_{at}(r) \times \hat{\mathbf{B}}(r). \tag{221}
\]

Note that by using Eqs. (70)–(72) together with the Maxwell equations (85) and (87), this equation can be given in the equivalent form

\[
\hat{\mathbf{F}}_L = \int d^3 r \left[ \hat{\rho}_{at}(r) \hat{\mathbf{E}}(r) + \hat{\mathbf{j}}_{at}(r) \times \hat{\mathbf{B}}(r) \right], \tag{222}
\]

which corresponds to the Eq. (110) used in Sec. 3 as a starting point for calculating dispersion forces on bodies.\(^{25}\)

From Eq. (221), the Lorentz force in long-wavelength approximation can be obtained by performing a leading-order expansion in the relative particle coordinates \(\hat{\mathbf{r}}_A\), resulting in

\[
\hat{\mathbf{F}}_L = \nabla_A \left[ \hat{\mathbf{d}} \cdot \hat{\mathbf{E}}(\hat{\mathbf{r}}_A) + \hat{\mathbf{m}} \cdot \hat{\mathbf{B}}(\hat{\mathbf{r}}_A) + \hat{\mathbf{d}} \times \hat{\mathbf{r}}_A \cdot \hat{\mathbf{B}}(\hat{\mathbf{r}}_A) \right] + \frac{d}{dt} \left[ \hat{\mathbf{d}} \times \hat{\mathbf{B}}(\hat{\mathbf{r}}_A) \right], \tag{223}
\]

[recall Eqs. (76) and (77)], where

\[
\frac{d}{dt} \left[ \hat{\mathbf{d}} \times \hat{\mathbf{B}}(\hat{\mathbf{r}}_A) \right] = \frac{i}{\hbar} \left[ \hat{\mathbf{H}}, \hat{\mathbf{d}} \times \hat{\mathbf{B}}(\hat{\mathbf{r}}_A) \right] = \hat{\mathbf{d}} \times \hat{\mathbf{B}}(\hat{\mathbf{r}}_A) + \hat{\mathbf{d}} \times \hat{\mathbf{B}}(\hat{\mathbf{r}}_A) \biggr|_{r=\hat{\mathbf{r}}_A} + \frac{1}{2} \hat{\mathbf{d}} \times \left[ \left[ \hat{\mathbf{r}}_A \cdot \nabla_A \right] \hat{\mathbf{B}}(\hat{\mathbf{r}}_A) + \hat{\mathbf{B}}(\hat{\mathbf{r}}_A) \left( \nabla_A \cdot \hat{\mathbf{r}}_A \right) \right]. \tag{224}
\]

Discarding all terms proportional to \(\hat{\mathbf{r}}_A\) (which are of the order \(v/c\) and thus negligible for nonrelativistic center-of-mass motion), as well as the contribution from the magnetic interactions, Eq. (223) reduces to

\[
\hat{\mathbf{F}}_L = \left\{ \nabla_A \left[ \hat{\mathbf{d}} \cdot \hat{\mathbf{E}}(\hat{\mathbf{r}}) \right] + \frac{d}{dt} \left[ \hat{\mathbf{d}} \times \hat{\mathbf{B}}(\hat{\mathbf{r}}) \right] \right\}_{r=\hat{\mathbf{r}}_A}, \tag{225}
\]

whose expectation value

\[
\mathbf{F} = \langle \hat{\mathbf{F}}_L \rangle \tag{226}
\]

quite generally provides a basis for calculating electromagnetic forces on nonmagnetic atoms, including dispersion forces. Needless to say that Eq. (225) is valid regardless of the state the atom and the body-assisted field are prepared in.

\(^{25}\)Note that the field created by the atom only gives rise to internal forces, so that one may equivalently write Eq. (222) with the total fields \(\hat{\mathbf{E}}(\mathbf{r})\) and \(\hat{\mathbf{B}}(\mathbf{r})\) [Eq. (83)] instead of \(\hat{\mathbf{E}}(\mathbf{r})\) and \(\hat{\mathbf{B}}(\mathbf{r})\).
At this point we recall that, according to Eqs. (33) and (36), the electric and the magnetic induction fields are expressed in terms of the dynamical variables \( \hat{f}_\lambda(r, \omega) \) and \( \hat{f}_3(r, \omega) \). It is not difficult to prove that in electric-dipole approximation, \( \hat{f}_3(r, \omega) \) obeys the Heisenberg equation of motion

\[
\hat{f}_3(r, \omega) = \frac{i}{\hbar} \left[ \hat{H}, \hat{f}_3(r, \omega) \right] = -i\omega \hat{f}_3(r, \omega) + \frac{i}{\hbar} \mathbf{d} \cdot \mathbf{G}_\lambda^* [\mathbf{r}_A, r, \omega]
\]  

(recall the Hamiltonian (99) together with Eqs. (100), (101), and (109)), whose formal solution reads

\[
\hat{f}_\lambda(r, \omega, t) = \hat{f}_{\text{free}}(r, \omega, t) + \hat{f}_{\text{ss}}(r, \omega, t),
\]

where

\[
\hat{f}_{\text{free}}(r, \omega, t) = e^{-i\omega(t-t_0)} \hat{f}_{\text{free}}(r, \omega, t_0)
\]

and

\[
\hat{f}_{\text{ss}}(r, \omega, t) = \frac{i}{\hbar} \int_{t_0}^{t} d\tau e^{-i\omega(t-\tau)} \hat{\mathbf{d}}(\tau) \cdot \mathbf{G}_\lambda^* [\mathbf{r}_A(\tau), r, \omega],
\]

respectively, determine the free-field parts \( \mathbf{E}_{\text{free}}(r, \omega, t) \), \( \mathbf{B}_{\text{free}}(r, \omega, t) \) and the source-field parts \( \mathbf{E}_s(r, \omega, t) \), \( \mathbf{B}_s(r, \omega, t) \) of the electric and the induction field in the \( \omega \) domain. Substitution of Eqs. (28)—(30) together with Eqs. (33) and (36) into Eq. (26) together with Eq. (25) and use of Eq. (34) leads to the following expression for the mean force [444,471],

\[
\mathbf{F}(t) = \mathbf{F}_{\text{free}}(t) + \mathbf{F}_s(t),
\]

where

\[
\mathbf{F}_{\text{free}}(t) = \int_0^\infty d\omega \left\{ \nabla \left\langle \hat{\mathbf{d}}(t) \cdot \mathbf{E}_{\text{free}}(r, \omega, t) \right\rangle \\
+ \frac{d}{dt} \left\langle \left[ \hat{\mathbf{d}}(t) \times \mathbf{B}_{\text{free}}(r, \omega, t) \right] \right\rangle \right\}^*_{r=\mathbf{r}_A(t)} + \text{H.c.}
\]

and

\[
\mathbf{F}_s(t) = \mathbf{F}_{s}^{\text{el}}(t) + \mathbf{F}_{s}^{\text{mag}}(t),
\]

with the components

\[
\mathbf{F}_{s}^{\text{el}}(t) = \left\{ \frac{i\mu_0}{\pi} \int_0^\infty d\omega \omega^2 \int_{t_0}^{t} d\tau e^{-i\omega(t-\tau)} \right. \\
\times \nabla \left\langle \hat{\mathbf{d}}(t) \cdot \text{Im} \mathbf{G}[\mathbf{r}, \mathbf{r}_A(\tau), \omega] \cdot \hat{\mathbf{d}}(\tau) \right\rangle \right\}^*_{r=\mathbf{r}_A(t)} + \text{H.c.}
\]
and
\[
F_{s}^{\text{mag}}(t) = \left\{ \frac{\mu_0}{\pi} \int_{t_0}^{\infty} d\omega \omega \frac{d}{dt} \int_{t_0}^{t} d\tau e^{-i\omega(t-\tau)} \right. \\
\times \left. \left\langle \hat{d}(t) \times \left( \nabla \times \text{Im} G[r, \hat{r}_A(\tau), \omega] \right) \cdot \hat{d}(\tau) \right\rangle \right\}_{r=\hat{r}_A(t)} + \text{H.c.} \quad (235)
\]

being related to the source-field parts of the electric and the induction field.

While Eq. (231) together with Eqs. (232)–(235) gives the force on an atom subject to an arbitrary electromagnetic field, we are interested in the pure dispersion force, which can be obtained by considering the special case where the (body-assisted) electromagnetic field is initially prepared in the ground state \(|\{0\}\rangle\) so that
\[
\langle \{0\}| \ldots \hat{E}_{\text{free}}(r, \omega, t)|\{0\}\rangle = \langle \{0\}| \ldots \hat{B}_{\text{free}}(r, \omega, t)|\{0\}\rangle = 0 \quad (236)
\]
[recall Eq. (52)], which implies that \(F_{\text{free}}(t) = 0\). Hence, Eq. (231) simply reduces to
\[
F(t) = F_s(t) \quad (237)
\]
in this case. Moreover, for chosen atomic position, \(\hat{r}_A\) may be regarded as being a time-independent c-number parameter \(|\hat{r}_A(t)\rangle \mapsto r_A\) so that the expectation values to be taken in Eqs. (234) and (235) only refer to the internal state of the atom. It should be pointed out that the concept is not restricted to the calculation of the mean force but can be extended to higher-order force moments (for a discussion of force fluctuations, see also Ref. [293]).

### 4.2.2 Weak atom–field coupling

The remaining task now consists in the determination of the dipole–dipole correlation function
\[
\langle \hat{d}(t) \hat{d}(\tau) \rangle = \sum_{m, n, m', n'} d_{mn} d_{m'n'} \langle A_{mn}(t) A_{m'n'}(\tau) \rangle \quad (238)
\]
in Eqs. (234) and (235) \(|\hat{A}_{mn} = |m\rangle \langle n|\), recall Eq. (101)]. To that end, the problem of the internal atomic dynamics must be solved. Let first consider the case of weak atom–field coupling, where the Markov approximation can be used to considerably simplify the problem. Under the assumption that the relevant atomic transition frequencies are well separated from one another, so that diagonal and off-diagonal density matrix elements evolve independently, application of the quantum-regression theorem (see, e.g., Ref. [439]) yields the familiar result
\[
\langle \hat{A}_{mn}(t) \hat{A}_{m'n'}(\tau) \rangle = \delta_{nn'} \langle \hat{A}_{mm}(\tau) \rangle e^{(i\omega_{mn}(r_A) - \Gamma_m(r_A) + \Gamma_n(r_A))/2}(t-\tau) \quad (239)
\]
Here,

\[ \tilde{\omega}_{mn}(r_A) = \omega_{mn} + \delta \omega_m(r_A) - \delta \omega_n(r_A) \]  

(240)

are the atomic transition frequencies including the position-dependent energy-level shifts\(^{26}\)

\[ \delta \omega_m(r_A) = \sum_k \delta \omega_m^k(r_A), \]  

(241)

\[ \delta \omega_m^k(r_A) = \frac{\mu_0}{\pi \hbar} \mathcal{P} \int_0^\infty d\omega \omega^2 \frac{ \mathbf{d}_{km}\cdot\text{Im} \mathbf{G}^{(1)}(r_A, r_A, \omega) \cdot \mathbf{d}_{mk} }{ \tilde{\omega}_{mk}(r_A) - \omega }, \]  

(242)

which are due to the interaction of the atom with the body-assisted electromagnetic field, and similarly,

\[ \Gamma_m(r_A) = \sum_k \Gamma_m^k(r_A), \]  

(243)

\[ \Gamma_m^k(r_A) = \frac{2\mu_0}{\hbar} \Theta[\tilde{\omega}_{mk}(r_A)] \tilde{\omega}_{mk}^2(r_A) \mathbf{d}_{km}\cdot\text{Im} \mathbf{G}[r_A, r_A, \tilde{\omega}_{mk}(r_A)] \cdot \mathbf{d}_{mk} \]  

(244)

are the position-dependent level widths. Note that the position-dependent energy shifts \( \hbar \delta \omega_m(r_A) \) as given by Eq. (241) together with Eq. (242) reduce to those obtained by leading-order perturbation theory, Eqs. (212)–(214), if the frequency shifts in the denominator on the r.h.s. of Eq. (242) are ignored.

Substituting Eqs. (238) and (239) into Eqs. (233)–(235), one can then show that the force on an atom that is initially prepared in an arbitrary state can be represented in the form \([444, 470, 471]\)

\[ \mathbf{F}(t) = \sum_{m,n} \sigma_{mn}(t) \mathbf{F}_{mn}(r_A), \]  

(245)

where the atomic density matrix elements \( \sigma_{mn}(t) = \langle \hat{A}_{mn}(t) \rangle \) solve the intra-atomic master equation together with the respective initial condition, and

\[ \mathbf{F}_{mn}(r_A) = \mathbf{F}_{mn}^{\text{el,or}}(r_A) + \mathbf{F}_{mn}^{\text{el,r}}(r_A) + \mathbf{F}_{mn}^{\text{mag,or}}(r_A) + \mathbf{F}_{mn}^{\text{mag,r}}(r_A), \]  

(246)

with the various electric/magnetic, off-resonant/resonant force components being given as follows:

\[ \mathbf{F}_{mn}^{\text{el,or}}(r_A) = -\frac{\hbar \mu_0}{2\pi} \int_0^\infty d\xi \xi^2 \times \left( \nabla \text{Tr} \left\{ [\mathbf{\alpha}_{mn}(r_A, i\xi) + \mathbf{\alpha}_{mn}(r_A, -i\xi)] \cdot \mathbf{G}^{(1)}(r_A, r_A, i\xi) \right\} \right)_{r=r_A}, \]  

(247)

\(^{26}\)The Lamb shifts observed in free space are again thought of as being already included in the frequencies \( \omega_{mn} \).
\[
F_{mn}^{el,r}(r_A) = \mu_0 \sum_k \Theta(\tilde{\omega}_{nk})\Omega_{mnk}^2(r_A) \\
\times \left\{ \nabla [d_{mk} \cdot G^{(1)}(r, r_A, \Omega_{mnk}(r_A)) \cdot d_{kn}] \right\}_{r=r_A} + \text{H.c.,} \quad (248)
\]

\[
F_{mn}^{\text{mag,or}}(r_A) = \frac{\hbar \mu_0}{2\pi} \int_0^\infty d\xi \xi^2 \text{Tr} \left\{ \frac{\tilde{\omega}_{mn}(r_A)}{i\xi} \alpha^T_{mn}(r_A) \right\} \\
- \frac{\tilde{\omega}_{mn}(r_A)}{i\xi} \left[ \nabla \times G^{(1)}(r, r_A, i\xi) \right] \left( \nabla \times G^{(1)}(r, r_A, i\xi) \right) \right\}_{r=r_A}, \quad (249)
\]

\[
F_{mn}^{\text{mag,r}}(r_A) = \mu_0 \sum_k \Theta(\tilde{\omega}_{nk})\tilde{\omega}_{mn}(r_A)\Omega_{mnk}(r_A) \\
\times \left\{ d_{mk} \times \nabla \times G^{(1)}(r, r_A, \Omega_{mnk}(r_A)) \cdot d_{kn} \right\}_{r=r_A} + \text{H.c.} \quad (250)
\]

\[
\text{[Tr } T_j = T_{lj}] \text{. Here, } \Omega_{mnk}(r_A) \text{ and } \alpha_{mn}(r_A, \omega) \text{ denote the complex atomic transition frequencies}
\]

\[
\Omega_{mnk}(r_A) = \tilde{\omega}_{nk}(r_A) + \frac{1}{2}[\Gamma_m(r_A) + \Gamma_k(r_A)] \quad (251)
\]

and the generalized polarizability tensor
\[
\alpha_{mn}(r_A, \omega) = \frac{1}{\hbar} \sum_k \left[ \frac{d_{mk} d_{kn}}{-\Omega_{mnk}(r_A) - \omega} + \frac{d_{kn} d_{mk}}{-\Omega_{mnk}^*(r_A) + \omega} \right]. \quad (252)
\]

Equations (245)–(250) show that the force components \( F_{mn}(r_A) \) \((m \neq n)\) associated with nonvanishing off-diagonal elements of the atomic density matrix contain contributions arising from the interaction of the atom with both the electric and the magnetic field, where the magnetic force components display a vector structure that is entirely different from that of the electric ones. Since, under the assumptions made, diagonal and off-diagonal density matrix elements are not coupled to each other so that
\[
\sigma_{nm}(t) = e^{i\tilde{\omega}_{mn}(r_A) t - [\Gamma_m(r_A) + \Gamma_n(r_A)]/2} (t - t_0) \sigma_{nm}(t_0) \quad (253)
\]

\((m \neq n)\), off-diagonal force components can only be observed if the atom is initially prepared in an at least partly coherent superposition of energy eigenstates. Accordingly, if the atom is initially prepared in an incoherent superposition of energy eigenstates, then only force components \( F_{mn}(r_A) \) which are associated with diagonal density-matrix elements and which are electrical by their nature,
\[
F_{mn}(r_A) = F_{mn}^{\text{el,or}}(r_A) + F_{mn}^{\text{el,r}}(r_A) = F_{mn}^{\text{or}}(r_A) + F_{mn}^{\text{r}}(r_A), \quad (254)
\]
are observed, with the density matrix elements obeying the balance equations

\[ \dot{\sigma}_{mm}(t) = -\Gamma_m(r_A)\sigma_{mm}(t) + \sum_k \Gamma_k^m(r_A)\sigma_{kk}(t). \]  

(255)

In particular, when the level shifts and broadenings are neglected, then the diagonal force components \( F_{mm}^{\text{or}}(r_A) \) and \( F_{mm}^{\text{r}}(r_A) \) as found from Eqs. (247) and (248) obviously reduce to those that are obtained from the perturbative potential (212)–(214) by means of Eq. (170). Note that the gradient in Eqs. (247) and (248) acts only on the Green tensor and not on the additional position-dependent quantities, so that this result cannot be derived from a potential in the usual way. Since the force components associated with excited-state density matrix elements are transient, they are only observable on time scales of the order of magnitude of the respective decay times \( \Gamma_m^{-1}(r_A) \), which are known to sensitively depend on the atomic position [439]. Needless to say that total force \( F(t) \) that acts on an initially excited atom approaches the ground-state force \( F_{00}(r_A) \) after sufficiently long times, \( \lim_{t\to\infty}\langle F(t) \rangle = F_{00}(r_A) \).

In order to illustrate the effect of the body-induced level shifting and broadening on the force, let us consider a two-level atom which is situated at distance \( z_A \) very close a dielectric half space. By means of the respective Green tensor (App. A) it turns out that in the nonretarded limit the shift and width of the transition frequency are determined by

\[ \delta\omega(z_A) = \delta\omega_1(z_A) - \delta\omega_0(z_A) = -\frac{d_{01}^2 + (d_{01} \cdot e_z)^2}{32\pi \varepsilon_0 \hbar z_A^3} \frac{|\varepsilon[\omega_0 + \delta\omega(z_A)]|^2 - 1}{|\varepsilon[\omega_0 + \delta\omega(z_A)] + 1|^2}, \]

(256)

\[ \Gamma(z_A) = \Gamma_1(z_A) = \frac{d_{01}^2 + (d_{01} \cdot e_z)^2}{8\pi \varepsilon_0 \hbar z_A^3} \frac{\text{Im} \varepsilon[\omega_0 + \delta\omega(z_A)]}{|\varepsilon[\omega_0 + \delta\omega(z_A)] + 1|^2}, \]

(257)

respectively, where the (small) off-resonant contribution to the frequency shift has been omitted. Note that due to the appearance of the frequency shift on the r.h.s. of Eq. (256), this equation determines the shift only implicitly. The dominant contribution to the force on the atom in the upper state is the resonant one, i.e., \( F_{11}(r_A) \approx F_{11}^r(r_A) \). Substituting the half-space Green tensor (App. A) into Eqs. (248) and (254), one can show that \( [F_{11}^r(r_A) = F_{11}^r(z_A)e_z] \) [444,470,471]

\[ F_{11}^r(z_A) = -\frac{3d_{01}^2 + (d_{01} \cdot e_z)^2}{32\pi \varepsilon_0 \hbar z_A^4} \frac{|\varepsilon[\Omega_{110}(z_A)]|^2 - 1}{|\varepsilon[\Omega_{110}(z_A)] + 1|^2}, \]

(258)

where, according to Eq. (251),

\[ \Omega_{110}(z_A) = \tilde{\omega}_{10}(z_A) + \frac{1}{2}\Gamma(z_A) = \omega_{10} + \delta\omega(z_A) + \frac{1}{2}\Gamma(z_A). \]

(259)

In particular, for a medium whose permittivity is of Drude–Lorentz type,
Fig. 6. The resonant component of the force on a two-level atom in the upper state placed in front of a dielectric half space, Eq. (258), is shown as a function of the unperturbed transition frequency $\omega_{10}$ (solid line) ($\omega_{pe}/\omega_{Te} = 0.75, \gamma_e/\omega_{Te} = 0.01, \omega_{pe}^2(d_0^2 + (d_0 \cdot e_z)^2)/3\pi\varepsilon_0 c^3 = 10^{-7}$, $z_A/\lambda_{Te} = 0.0075$, $\lambda_{Te} = 2\pi c/\omega_{Te}$). For comparison, both the perturbative result as obtained from Eq. (214) (dashed lines) and the separate effects of level shifting (dotted lines) and level broadening (dash-dotted lines) are shown.

Eq. (204) leads to ($\gamma_e, \Gamma \ll \omega_{Te}$)

$$\varepsilon[\Omega_{110}(z_A)] = 1 + \frac{\omega_{pe}^2}{\omega_{pe}^2 - \omega_{10}^2(z_A) - i[\Gamma(z_A) + \gamma_e]\omega_{10}(z_A)},$$

(260)

showing that the absorption parameter of the medium, $\gamma_e$ is replaced with the total absorption parameter, i.e., the sum of $\gamma_e$ and the spontaneous-decay constant $\Gamma(z_A)$ of the atom. Figure 6 displays the resonant component of the force on a two-level atom in the upper state placed near a (single-resonance) dielectric half space as a function of the unperturbed transition frequency $\omega_{10}$. It is seen that in the vicinity of the (surface-plasmon) frequency $\omega_S = \sqrt{\omega_{pe}^2 + \omega_{pe}^2/2}$ an enhanced force is observed, which is attractive (repulsive) for red (blue) detuned atomic transition frequencies $\omega_{10} < \omega_S$ ($\omega_{10} > \omega_S$)—a result already known from perturbation theory. However, it is also seen that due to body-induced level shifting and broadening the absolute value of the force can be noticeably reduced. Interestingly, the positions of the extrema of the force remain nearly unchanged, because level shifting and broadening give rise to competing effects that almost cancel.

The calculation of the off-resonant component of the force, Eq. (254) together
with Eq. (247), leads to \( F_{11}^{\text{eq}}(r_A) = F_{11}^{\text{eq}}(z_A) e_z \)

\[
F_{11}^{\text{eq}}(z_A) = \frac{3[d_{01}^2 + (d_{01} \cdot e_z)^2]}{32\pi^2 \varepsilon_0 \hbar z_A^3} \int_0^\infty d\xi \frac{\varepsilon(i\xi) - 1}{\varepsilon(i\xi) + 1} \times \frac{\tilde{\omega}_{10}(z_A)}{\tilde{\omega}_{10}^2(z_A) + [\xi + \Gamma(z_A)/2]^2} \frac{\tilde{\omega}_{10}^2(z_A) + \xi^2 + \Gamma^2(z_A)/4}{\tilde{\omega}_{10}^2(z_A) + [\xi - \Gamma(z_A)/2]^2}.
\] (261)

Equation (261) reveals that the off-resonant component of the force is only weakly influenced by the level broadening [the leading-order dependence being \( O(\Gamma^2) \)], which is in agreement with the physical requirement that the virtual emission and absorption processes governing the off-resonant component should be only weakly affected by decay-induced broadening. Formally, the absence of a linear-order term \( O(\Gamma) \) is due to the fact that the atomic polarizability (252) enters the off-resonant force components (247) only in the combination \( \alpha_{mm}(r_A, i\xi) + \alpha_{mm}(r_A, -i\xi) \), which could not have been anticipated from the perturbative result (213) [where in fact, \( \alpha_m(r_A, i\xi) \) and \( \alpha_m(r_A, -i\xi) \) coincide, recall Eq. (215)]. The effects of level shifting and broadening are illustrated in Fig. 7. Compared to the perturbative result, the frequency shift has the effect of raising or lowering the the force for \( \omega_{10} < \omega_S \) or \( \omega_{10} > \omega_S \), respectively, whereas the effect of broadening is not visible in the curves. Only by plotting the difference between the results with and without broadening, a slight reduction of the force becomes visible in the vicinity of \( \omega_S \), where \( \Gamma \) is largest. Since this behavior is generally typical of off-resonant components, the perturbative result may be regarded as a good approximation for the force on a ground-state atom, where no resonant components are present.

4.2.3 Strong atom–field coupling

Strong atom–field coupling may occur if an initially excited atom interacts resonantly with a sharply peaked (quasi-)mode of a body-assisted field, as it is observed in cavity-like systems. In this case the atom–field dynamics can no longer be described within the Markov approximation. Typically, a single atomic transition is in resonance with such a mode, so the dispersion force resulting from the atom–field interaction can be studied, to a good approximation, by employing the two-level model in rotating-wave approximation\(^{27}\) with respect to the interaction Hamiltonian (109). To be more specific, let us consider the resonant interaction of a two-level atom initially prepared in the upper state \(|1\rangle\) with the body-assisted electromagnetic field in the ground state \(|\{0\}\rangle\) and calculate the electric part of the resonant component of the force acting on the atom, i.e., in the Schrödinger picture,

\[
\mathbf{F}(t) \simeq \langle \psi(t) | \{ \nabla [\mathbf{d} \cdot \mathbf{E}(\mathbf{r})] \} \rangle_{r=r_A} | \psi(t) \rangle,
\] (262)

\(^{27}\) See, e.g., Ref. [439].
Fig. 7. The off-resonant component of the force on a two-level atom in the upper state placed in front of a dielectric half space, Eq. (261), is shown as a function of the unperturbed transition frequency (solid line), the parameters being the same as in Fig. 6. For comparison, both the perturbative result is also shown (dashed lines). The inset displays the difference between the force with and without consideration of level broadening (solid lines). In addition, the same difference is displayed when the level shifts are ignored (dashed lines).

with the state vector \(|\psi(t)\rangle [|\psi(t = t_0)\rangle = |\{0\}\rangle|1\rangle]\) being represented in the form

\[
|\psi(t)\rangle = \psi_1(t)|\{0\}\rangle|1\rangle + \int_0^\infty d\omega \frac{\psi_0(\omega, t)}{\hbar g(r_A, \omega)} \sum_{\lambda=e,m} \int d^3r d_{01} \cdot G^*_\lambda(r_A, r, \omega) \cdot |1(r_A, \omega)\rangle|0\rangle. \tag{263}
\]

It is normalized to unity provided that

\[
|\psi_1(t)|^2 + \int_0^\infty d\omega |\psi_0(\omega, t)|^2 = 1 \tag{264}
\]

and

\[
g^2(r_A, \omega) = \frac{\mu_0}{\hbar \pi} \omega^2 d_{01} \cdot \text{Im} G(r_A, r, \omega) \cdot d_{10}. \tag{265}
\]

Substituting Eq. (263) into the Schrödinger equation

\[
i\hbar \frac{\partial}{\partial t} |\psi(t)\rangle = \hat{H} |\psi(t)\rangle, \tag{266}
\]
with \( \hat{H} \) being given according to Eqs. (99) together with Eqs. (100), (101), and (109), one obtains the following coupled differential equations for \( \psi_1(t) \) and \( \psi_0(\omega, t) \):

\[
\dot{\psi}_1(t) = -\frac{i}{\hbar} E_1 \psi_1(t) + i \int_0^\infty d\omega \, g(\mathbf{r}_A, \omega) \psi_0(\omega, t), \quad (267)
\]

\[
\dot{\psi}_0(\omega, t) = -\frac{i}{\hbar} (E_0 + \hbar \omega) \psi_0(\omega, t) + ig(\mathbf{r}_A, \omega) \psi_1(t). \quad (268)
\]

Equation (268) together with the initial condition \( \psi_0(\omega, t=t_0) \equiv 0 \) can be formally integrated in a straightforward way. Inserting the result into Eqs. (263) and (267) then yields

\[
|\psi(t)\rangle = \psi_1(t)|\{0\}\rangle|1\rangle + \frac{i}{\hbar} \int_{t_0}^t d\tau \, \psi_1(\tau) \int_0^\infty d\omega \, e^{-i(E_0/\hbar + \omega)(t-\tau)}
\times \sum_{\lambda=e,m} \int d^3r \, d_{01} \cdot \mathbf{G}_\lambda^*(\mathbf{r}_A, \mathbf{r}, \omega) \cdot |1(\mathbf{r}_A, \omega)\rangle|0\rangle, \quad (269)
\]

and

\[
\dot{\psi}_1(t) = -i \frac{E_1}{\hbar} \psi_1(t) - \int_{t_0}^t d\tau \, \psi_1(\tau) \int_0^\infty d\omega \, e^{-i(E_0/\hbar + \omega)(t-\tau)} g^2(\mathbf{r}_A, \omega) \quad (270)
\]

respectively. Combining Eqs. (262) and (269) and making use of the integral relation (34), one finds that

\[
\mathbf{F}(t) = \frac{i \mu_0}{2\pi} \dot{\psi}_1^*(t) \int_0^t d\tau \, \psi(\tau) \int_0^\infty d\omega \, \omega^2 e^{-i(E_0/\hbar + \omega)(t-\tau)} \times \left\{ \nabla \left[ \text{Im} \mathbf{G}^{(1)}(\mathbf{r}, \mathbf{r}, \omega) \cdot d_{01}\right] \right\}_{\mathbf{r}=\mathbf{r}_A} + \text{H.c.} \quad (271)
\]

Since so far nothing has been said about the strength of the atom–field coupling, Eq. (271) gives the electric resonant component of the dispersion force on a two level atom which is initially prepared in the upper state for arbitrary coupling strengths.

Let us approximate that part of the excitation spectrum of the body-assisted electromagnetic field which may give rise to strong atom–field coupling in the resonant transition by a Lorentzian,

\[
g^2(\mathbf{r}_A, \omega) = g^2(\mathbf{r}_A, \omega_\nu) \frac{\gamma_\nu^2}{(\omega - \omega_\nu)^2 + \gamma_\nu^2} + g^2(\mathbf{r}_A, \omega) \quad (272)
\]

(\( \omega_\nu \approx \omega_{10} \)), and assume that the effect of the residual part of the field which is described by the term \( g^2(\mathbf{r}_A, \omega) \) is weakly coupled to the atom, so that it can be treated in the Markov approximation. From Eq. (270) it then follows that

\[
\dot{\psi}_1(t) = e^{-iE_1/\hbar - i\delta \omega_1(\mathbf{r}_A) - \Gamma(\mathbf{r}_A)/2(t-t_0)} \phi_1(t), \quad (273)
\]

\[\text{[Page 67]}\]
where \( \phi_1(t) \) is the solution to the differential equation

\[
\ddot{\phi}_1(t) + \left[ i \Delta (r_A) + \gamma_v - \frac{1}{2} \Gamma_1' (r_A) \right] \dot{\phi}_1(t) + \frac{1}{4} \Omega_R^2 (r_A) \phi_1(t) = 0
\]  

(274)

together with the initial conditions \( \phi_1(t = t_0) = 1 \), \( \dot{\phi}_1(t = t_0) = 0 \). Here, \( \Delta (r_A) = \omega_v - \bar{\omega}_10(r_A) \) and \( \Omega_R (r_A) = \sqrt{4 \pi \gamma_v g^2 (r_A, \omega_v)} \), respectively, are the detuning and the vacuum Rabi frequency, and

\[
\delta \omega_1'(r_A) = \delta \omega_1(r_A) + \frac{1}{4} \Omega_R^2 (r_A) \frac{\Delta (r_A)}{\Delta^2 (r_A) + \gamma_v^2},
\]  

(275)

and

\[
\Gamma_1' (r_A) = \Gamma_1 (r_A) - \frac{1}{2} \Omega_R^2 (r_A) \frac{\gamma_v}{\Delta^2 (r_A) + \gamma_v^2}
\]  

(276)

are the shift and width of the upper level associated with the residual part of the field [for \( \delta \omega_1 (r_A) \) and \( \Gamma_1 (r_A) \), recall Eqs. (241)–(244)], with the respective shifted transition frequency being given by \(^{28}\)

\[
\bar{\omega}_10'(r_A) = \omega_10 + \delta \omega_1'(r_A)
\]  

(277)

Equation (274) can easily be solved to obtain

\[
\phi_1(t) = c_+ (r_A) e^{\Omega_+ (r_A) t} + c_- (r_A) e^{\Omega_- (r_A) t},
\]  

(278)

where

\[
c_{\pm} (r_A) = \frac{\Omega_{\mp} (r_A)}{\Omega_{\pm} (r_A) - \Omega_{\mp} (r_A)}
\]  

(279)

and

\[
\Omega_{\pm} (r_A) = - \frac{1}{2} \left[ i \Delta (r_A) + \gamma_v - \frac{1}{2} \Gamma_1' (r_A) \right]
\]

\[
\pm \frac{1}{2} \sqrt{\left[ i \Delta (r_A) + \gamma_v - \frac{1}{2} \Gamma_1' (r_A) \right]^2 - \Omega_R^2 (r_A)}.
\]  

(280)

Combining Eqs. (271), (273), and (278), the sought force reads

\[
F(t) = \frac{\mu_0}{2 \pi} \int_0^\infty d \omega \, \omega^2 \mathcal{M}(r_A, \omega, t - t_0) \left\{ \nabla \left[ d_{10} \cdot \text{Im} G^{(1)} (r, r_A, \omega) \cdot \mathbf{d}_{01} \right] \right\}_{r = r_A} + \text{H.c.},
\]  

(281)

\(^{28}\) Note that contrary to Eq. (240), the ground-state shift is absent here as a consequence of the rotating-wave approximation.
where

\[
\begin{align*}
\langle r_A, \omega, t \rangle \\
= |c_+ (r_A)|^2 e^{[-\Gamma^+_1(r_A) + \Omega^+_0(r_A) + \Omega^+_+ (r_A)] t} - e^{i[\omega^0_1 (r_A) - \omega - \Gamma^+_0 (r_A)/2 + \Omega^+ (r_A)] t} \\
+ c_+ (r_A) c_- (r_A) e^{[\omega - \omega^0_0 (r_A) + i \Gamma^+_1 (r_A)/2 - i \Omega^- (r_A)] t} \\
+ c_+ (r_A) c_- (r_A) e^{[-\Gamma^+_1 (r_A) + \Omega^+_0 (r_A) + \Omega^- (r_A)] t} - e^{i[\omega^0_1 (r_A) - \omega - \Gamma^+_0 (r_A)/2 + \Omega^+ (r_A)] t} \\
+ |c_- (r_A)|^2 e^{[-\Gamma^+_1 (r_A) + \Omega^+_0 (r_A) + \Omega^- (r_A)] t} - e^{i[\omega^0_1 (r_A) - \omega - \Gamma^+_0 (r_A)/2 + \Omega^+ (r_A)] t} \\
\end{align*}
\]

\[
(282)
\]

Let us first make contact with result obtained in the limit of weak atom-field coupling when the first term under the square root in Eq. (280) is much larger than the second one. This is typically the case when the condition

\[
\gamma_\nu \gg \Omega_R (r_A)
\]

is satisfied, i.e., when, for given transition dipole moment, the spectrum of the field in the resonance region is sufficiently flat. By means of Taylor expansion it can then be shown that

\[
\begin{align*}
\Omega^+_0 (r_A) &\simeq \frac{i}{2} \Omega^2_R (r_A) \frac{\Delta (r_A)}{\Delta^2 (r_A)} + \frac{\gamma_\nu}{2} \frac{\Omega^2_R (r_A)}{\Delta^2 (r_A)} \\
\Omega^- (r_A) &\simeq -i \Delta (r_A) - \gamma_\nu,
\end{align*}
\]

(284)

so Eq. (281) [together with Eq. (282)] approximates to \((c_+ \simeq 1, c_- \simeq 0)\)

\[
\begin{align*}
\mathbf{F}(t) &= e^{-\Gamma_1 (r_A)(t-t_0)} \frac{\mu_0}{2\pi \int_0^\infty} d\omega \omega^2 \left\{ \nabla \left[ \mathbf{d}_{10} \cdot \text{Im} \mathbf{G}^{(1)} (r, r, \omega) \cdot \mathbf{d}_{01} \right] \right\} + \text{H.c.} \\
&\simeq e^{-\Gamma_1 (r_A)(t-t_0)} \mu_0 [\omega_1 (r_A) + i \Gamma_1 (r_A)/2]^2 \\
&\quad \times \left( \nabla \left[ \mathbf{d}_{10} \cdot \mathbf{G}^{(1)}[r, r_A, \omega_1 (r_A) + i \Gamma_1 (r_A)/2] \cdot \mathbf{d}_{01} \right] \right) + \text{H.c.},
\end{align*}
\]

(285)

which corresponds to the term \(\sigma_{11}(t) \mathbf{F}^{11}_{11} (r_A)\) in Eqs. (245) and (246), with \(\mathbf{F}^{11}_{11} (r_A)\) according to Eq. (248).

The opposite, strong-coupling limit is realized if the spectrum of the field in the resonance region features a sharp peak such that

\[
\gamma_\nu \ll \Omega_R (r_A).
\]

(286)
In this case the second term under the square root in Eq. (280) is much larger than the first one, so by neglecting the small real part of the square root we have
\[ \Omega_{\pm}(r_A) \approx -\frac{i}{2} \left[ i \Delta_{\nu}(r_A) + \gamma_{\nu} - \frac{1}{2} \Gamma_1'(r_A) \right] \pm \frac{i}{2} \Omega(r_A), \] (287)
where
\[ \Omega(r_A) = \sqrt{\Omega_R^2(r_A) + \Delta^2(r_A)}. \] (288)
By introducing the coupling angle \( \theta(r_A) \) according to
\[ \tan[2\theta(r_A)] = -\frac{\Omega_R(r_A)}{\Delta(r_A)}, \quad \theta(r_A) \in (0, \pi/2), \] (289)
the coefficients \( c_{\pm}(r_A) \) [Eq. (279)] can be given in the form
\[ c_+ = \sin^2[\theta(r_A)], \quad c_- = \cos^2[\theta(r_A)]. \] (290)
Substituting Eqs. (287) and (290) into Eq. (281) [together with Eq. (282)], one can then show that \( F(t) \) approximates to
\[ F(t) = \frac{1}{2} \hbar \cos[2\theta(r_A)] e^{-[\gamma_{\nu} + \Gamma_1'(r_A)/2]/(t-t_0)} \left\{ \cos[\Omega(r_A)t - 1] \right\} \nabla_A \Omega(r_A). \] (291)
Note that \( \gamma_{\nu} + \Gamma_1'(r_A)/2 = \gamma_{\nu} \) if \( \Delta(r_A) \ll \gamma_{\nu} \), and \( \gamma_{\nu} + \Gamma_1'(r_A)/2 = \Gamma_1(r_A)/2 \) if \( \gamma_{\nu} \ll \Delta(r_A) \).

Comparing Eq. (291) with Eq. (285) we see that while the resonant component of the force in the weak-coupling limit simply exponentially decreases as a function of time, Rabi oscillations of the force are typically observed in the strong-coupling limit—in agreement with the well-known features of spontaneous emission in the two coupling regimes. As a consequence of the appearance of Rabi oscillations, the sign of the force changes periodically so that, under certain conditions, the atom may be trapped, with the trap being set by the atom itself, cf. also Refs. [477,478]. Rabi oscillations do not occur if the system is initially prepared in a dressed state; in this case the force is simply given by the gradient of the position-dependent part \( \pm \hbar \Omega(r_A)/2 \) [recall Eq. (288)] of the respective dressed-state energy [479,480].

5 Concluding remarks

Dispersion forces are a particular signature of the interaction of matter with the quantized electromagnetic field. As soon as the interacting matter consists of a large number of elementary atomic particles, exact microscopic calculations become very involved. Therefore most theoretical approaches to dispersion forces make use of assumptions from macroscopic electrodynamics, by introducing—sooner or later—familiar macroscopic concepts such as
boundary conditions at surfaces of discontinuity and/or constitutive relations averaged over a sufficiently large number of the elementary constituents of the respective material objects. Macroscopic electrodynamics, whose applicability surprisingly ranges even to nano-structures, has the benefit of being universally valid, because it uses only very general physical properties, without the need of involved ab initio calculations. Moreover, all the relevant quantities used for characterizing the material objects can easily be inferred from measurements. This concept does not only apply to classical electrodynamics but also to QED, where, as demonstrated, a consistent description of the quantized electromagnetic field in the presence of linear, causal media can be obtained. The scheme has been well elaborated for the case of locally responding media described in terms of complex-valued, position- and frequency-dependent permittivities and permeabilities. It can be extended to arbitrary linear media, including spatially dispersing media, since the description of the quantized field in terms of current densities and the Green tensor associated with the macroscopic Maxwell equations is independent of the particular medium description. When supplemented with standard atom-field coupling terms, a powerful tool for studying medium-assisted quantum effects in QED is obtained. Clearly, the applicability of the theory is restricted to body-body and body-atom separations that are sufficiently large compared with the length scale on which the atomistic structure of the bodies begins to play a role.

As demonstrated in this article, the so established macroscopic QED provides for a unified approach to the various types of dispersion forces—an approach which incorporates the benefits of normal-mode and linear-response approaches, while exactly taking into account real material properties. In particular, dispersion forces between electrically neutral, unpolarized and unmagnetized ground-state bodies simply reflect the forces, which are due to the action of the fluctuating body-assisted electromagnetic vacuum on the fluctuating charge and current densities of the bodies. Since all the relevant characteristics of the bodies enter the so obtained force formulas via the Green tensor of the associated macroscopic Maxwell equations, they are valid for arbitrary bodies. Both the Casimir stress and the Casimir force density can naturally be introduced in this way. Moreover, by appropriate Born-series expansions of the Green tensor, relations between dispersion forces on bodies and dispersion forces on atoms can be established, which clearly demonstrate common origin of all these forces. In particular, the force on an atom in the presence of arbitrary bodies as well as the force between two atoms can be obtained as limiting cases of the body-body force.

In the present article we have restricted our attention to ground-state bodies, i.e, to bodies that at zero temperature interact with the electromagnetic field, where the effect of dispersion forces is purely quantum by its nature. It is straightforward to include equilibrium systems at finite temperatures in the
theory, by simply replacing the vacuum averages in the basic formulas by thermal averages. In this context it should be pointed out that the central assumption of linear response theories according to which the thermal average of the field fluctuations is related to the imaginary part of the field response function is explicitly fulfilled within the framework of macroscopic QED.

As we have seen, dispersion forces on ground-state atoms turn out to be limiting cases of dispersion forces on macroscopic bodies, so the corresponding formulas can be obtained without explicitly addressing the underlying atom–field interaction. Of course, they can also be derived by explicitly solving the quantum-mechanical problem of individual atoms interacting with the electromagnetic field, with the presence of macroscopic bodies being again described within the framework of macroscopic QED. For ground-state atoms, where only virtual transitions occur, this leads to results that agree with the ones obtained from the macroscopic approach, as expected. In fact, the approach is more flexible, because it can also be applied to nonequilibrium systems, such as initially excited atoms, where also real transitions are involved in the atom–field interaction. In this case, a dynamical description is in general preferred to be employed, leading to time-dependent expressions for the forces, according to the temporal evolution of the atomic quantum state. In particular for weak atom–field coupling, the force on an initially excited atom is a sum of components whose temporal evolution follows that of the associated atomic density matrix elements, which is in turn governed by the familiar master equation of an atomic system undergoing radiative damping. For strong atom–field coupling, damped Rabi oscillations may occur, which periodically change the sign of the force. The dynamical approach could serve as a starting point for studying dispersion forces on bodies that are not in thermal equilibrium, by appropriately modeling such bodies as collections of excited atoms [280,281].

Including linearly responding bodies in macroscopic QED has the advantage that from the very beginning of all calculations the effect of the bodies is taken into account in a consistent manner, without the need to specify the properties of the bodies at an early stage. In this way very general results of broad applicability can be obtained. This naturally applies not only to dispersion forces, but also to other quantum phenomena of radiation–matter interaction which are strongly influenced by the presence of macroscopic bodies—phenomena that may be subsumed under the term Casimir effect in the broadest sense of the word. Typical examples are the enhancement and inhibition of spontaneous emission, resonant energy transfer between atoms or molecules, and the wide field of cavity-QED effects.

A Green tensors

The Green tensor in free space is given by [437]

\[ G_{\text{free}}(\mathbf{r}, \mathbf{r}', i\xi) = \frac{1}{3} \left( \frac{e}{\xi} \right)^2 \delta(\rho) I + \frac{e^2 e^{-\xi \rho/c}}{4\pi \xi^2 \rho^3} \left[ a(\xi \rho/c) I - b(\xi \rho/c) e_\rho e_\rho \right] \] (A.1)

(\rho = r - r'; \rho = |\rho|; e_\rho = \rho/\rho), where

\[ a(x) = 1 + x + x^2, \quad b(x) = 3 + 3x + x^2. \] (A.2)

The scattering Green tensor for the planar magnetodielectric structure characterized by Eqs. (130) and (131) is given by [461,481]

\[ G^{(1)}(\mathbf{r}, \mathbf{r}', i\xi) = \int d^2 q \, e^{i\mathbf{q} \cdot (\mathbf{r} - \mathbf{r}')} G^{(1)}(\mathbf{q}, z, z', i\xi) \quad \text{for} \ 0 < z, z' < d \] (A.3)

(q \perp e_z), where

\[ G^{(1)}(\mathbf{q}, z, z', i\xi) = \frac{\mu(i\xi)}{8\pi^2 b} \sum_{\sigma = s, p} \left\{ \frac{r_{\sigma - r_{\sigma +} e^{-2b d}}}{D_{\sigma}} \left[ e_\sigma^+ e_\sigma^+ e^{-b(z - z')} + e_\sigma^- e_\sigma^- e^{b(z - z')} \right] \right\} + \frac{1}{D_{\sigma}} \left[ e_\sigma^+ e_\sigma^- r_{\sigma -} e^{-b(z + z')} + e_\sigma^- e_\sigma^+ r_{\sigma +} e^{-2b d} e^{b(z + z')} \right]. \] (A.4)

Here, b and D_{\sigma} are defined by Eqs. (135) and (136), respectively,

\[ e_{s, p}^\pm = e_q \times e_z, \quad e_{s, p}^\pm = -\frac{1}{k} (i q e_x \pm be_y) \] (A.5)

(e_q = q/q, q = |q|) with

\[ k = \frac{\xi}{c} \sqrt{\varepsilon(\tau \xi) \mu(\tau \xi)} \] (A.6)

are the polarization vectors for s- and p-polarized waves propagating in the positive (+) and negative (−) z-directions, and r_{\sigma}^\pm = r_{\sigma}^\pm(\xi, q) with \sigma = s, p describe the reflection of these waves at the right (+) and left (−) walls, respectively.

In particular, assume that both walls are multi-slab magnetodielectrics consisting of N_\pm homogeneous layers of thicknesses d_\pm^j (j = 1, \ldots, N_\pm) with d_\pm^{N_\pm} = \infty, permittivity \varepsilon_\pm^j(\omega), and permeability \mu_\pm^j(\omega). In this case the reflection
coefficients can be obtained from the recurrence relations \( r_{\sigma \pm} = r_{\sigma \pm}^0; \quad d \equiv d_0^\pm \); \( \varepsilon(\omega) = \varepsilon_0^\pm(\omega); \quad \mu(\omega) = \mu_0^\pm(\omega) \)

\[
\begin{align*}
    r_{s \pm}^j &= \frac{(\mu_{\pm}^{j+1}b_{\pm}^j - \mu_{\pm}^{j}b_{\pm}^{j+1}) + (\mu_{\pm}^{j+1}b_{\pm}^{j+1} + \mu_{\pm}^{j}b_{\pm}^{j}) e^{-2b_{\pm}^{j+1}d_{\pm}^{j+1}} \tau_{s \pm}^{j+1}}{(\mu_{\pm}^{j+1}b_{\pm}^j + \mu_{\pm}^{j}b_{\pm}^{j+1}) + (\mu_{\pm}^{j+1}b_{\pm}^{j+1} - \mu_{\pm}^{j}b_{\pm}^{j}) e^{-2b_{\pm}^{j+1}d_{\pm}^{j+1}} \tau_{s \pm}^{j+1}}, \\
    r_{p \pm}^j &= \frac{\varepsilon_{j+1}^\pm b_{j+1}^\pm - \varepsilon_{j}^\pm b_{j+1}^\pm + (\varepsilon_{j+1}^\pm b_{j+1}^\pm - \varepsilon_{j}^\pm b_{j+1}^\pm) e^{-2b_{j+1}^\pm d_{j+1}^\pm r_{p \pm}^{j+1}}}{(\varepsilon_{j+1}^\pm b_{j+1}^\pm + \varepsilon_{j}^\pm b_{j+1}^\pm) + (\varepsilon_{j+1}^\pm b_{j+1}^\pm - \varepsilon_{j}^\pm b_{j+1}^\pm) e^{-2b_{j+1}^\pm d_{j+1}^\pm r_{p \pm}^{j+1}}}.
\end{align*}
\] (A.7) (A.8)

\((j = 0, \ldots, N_\pm - 1)\) with \( r_{\sigma \pm}^{N_\pm} = 0 \), where

\[
b_{\pm}^j = \sqrt{\frac{\xi_2^2}{c^2} \varepsilon_{\pm}^j(i\xi)\mu_{\pm}^j(i\xi) + q^2}.
\] (A.9)

For single, semi-infinite slabs, Eqs. (A.7) and (A.8) reduce to the Fresnel coefficients

\[
r_{s \pm} = \frac{\mu_{\pm}^{1}b - \mu_{\pm}^{1}b_{\pm}^{1}}{\mu_{\pm}^{1}b + \mu_{\pm}^{1}b_{\pm}^{1}}, \quad r_{p \pm} = \frac{\varepsilon_{1}^\pm b_{\pm}^{1} - \varepsilon_{1}^\pm b_{\pm}^{1}}{\varepsilon_{1}^\pm b_{\pm}^{1} + \varepsilon_{1}^\pm b_{\pm}^{1}}.
\] (A.10)
