We investigate the properties of different levels of entanglement in graph states which correspond to connected graphs. Combining the operational definition of graph states and the postulates of entanglement measures, we prove that in connected graph states of \( N \) qubits there is no genuine \( k \)-qubit entanglement, \( 2 \leq k \leq N - 1 \), among every \( k \) qubits. These results about connected graph states naturally lead to the definition of maximally genuine multi-qubit entangled states. We also find that the connected graph states of four qubits is one but not the only one class of maximally genuine four-qubit entangled states.

I. INTRODUCTION

The trend of quantum information processing is to implement large scale quantum computation with many qubits \([1, 2, 3, 4]\). One prospective proposal is the one-way quantum computation model, based on some special kind of multi-particle entangled states and single qubit measurements \([5]\). The universal resource in one-way quantum computer is the so called graph states that correspond to mathematical graphs \([6]\), where the vertices of the graph play the role of quantum spin systems and edges represent Ising interactions. Graph states also have applications in quantum communication of many users, e.g. open destination quantum teleportation \([7]\). Moreover, various quantum error correcting codes for protecting quantum information against decoherence are also graph states \([8]\).

On the other hand, it is well known that entanglement is the most fascinating feature of quantum mechanics. Very recently, entanglement in interacting many-body systems becomes an increasing important concept in condensed matter physics, such as quantum phase transitions \([9]\), superconductivity and fractional quantum Hall effect \([10]\). However, the structure and nature of entanglement in multi-particle entangled states is not very clear now. The most obstacle is that there is no known measure which can completely characterize the entanglement of multi-particle entangled states. Therefore, the study of entanglement properties of the special significant multi-particle entangled states - graph states is a very important and interesting topic \([11, 12, 13, 14, 15, 16]\).

In Refs. \([12]\), Hein et al characterize and quantify the genuine multi-particle entanglement of graph states by the Schmidt measure. They provide the upper and lower bounds of the Schmidt measure \([17]\) in graph theoretical terms. In this paper, we investigate the entanglement properties of graph states from the viewpoint of different levels of entanglement. The main result is that, using the operational description of graph states and the fact that entanglement measures always decrease under local operations and classical communications (LOCC), we present a simple proof that in general connected graph states of \( N \) qubits, genuine \( k \)-qubit entanglement, \( 2 \leq k \leq N - 1 \), among every \( k \) qubits always vanish. These results explicitly demonstrate that graph states is indeed a kind of maximally genuine multi-qubit entangled states. In addition, we find that the connected graph states of four qubits is only one class of maximally genuine multi-qubit entangled states. We construct different kinds of maximally genuine multi-qubit entangled states that are not local unitary equivalent to connected graph states of four qubits.

II. GRAPH STATES

Each mathematical (undirected, finite) graph is denoted as \([18]\)

\[
G = (V, E)
\]

where the finite set \( V \subset N \) is the set of vertices, and the set \( E \subset [V]^2 \) is the set of edges. In the context of graph states, people restrict to the simple graphs, which contain neither edges connecting vertices with itself nor multiple edges. Given a subset of vertices \( S \subset V \), we can define the subgraph generated by \( S \) as \( G_S = (S, E_S) \), where \( E_S \subset E \), and for every edges \( \{a, b\} \in E \), if and only if \( a, b \in S \) then \( \{a, b\} \in E_S \).

For a given vertex \( a \in V \), its neighborhood \( N_a \subset V \) is defined as the set of vertices adjacent to the given vertex \( a \), i.e. the set of vertices \( b \in V \) for which \( \{a, b\} \in E \). For two vertices \( a, b \in V \), we say \( a \) and \( b \) is connected if there exists an ordered list of vertices \( a = a_1, a_2, \ldots, a_n = b \) such that for all \( i \), \( (a_i, a_{i+1}) \in E \). If any two \( a, b \in V \) are connected, the graph is a connected graph, otherwise it is a disconnected graph which can be viewed as a collection of several separate connected subgraphs.

Graph states that correspond to a mathematical graphs \( G = (V, E) \) is a certain pure quantum state on

*Electronic address: zwzhou@ustc.edu.cn
the Hilbert space $H = (C^2)^{\otimes N}$, where $N = |V|$ is the number of the vertices. For every vertex $a \in V$ of the graph $G = (V, E)$, one can define a Hermitian operator,

$$K^a_G = X_a \bigotimes_{b \in N_a} Z_b$$  \hspace{1cm} (2)

where the matrices $X_a$, $Y_a$ and $Z_a$ are Pauli matrices, the lower index specifies the qubit on which the operators acts. The graph state $|G\rangle$ associated with the graph $G = (V, E)$ is the unique $n$-qubit state fulfilling

$$K^a_G |G\rangle = |G\rangle$$ \hspace{1cm} (3)

The graph state $|G\rangle$ can be obtained by applying a sequence of unitary two-qubit operations to the initial state $|+\rangle^{\otimes N}$ as follows,

$$|G\rangle = \prod_{\{a, b\} \in E} U_{ab} |+\rangle^{\otimes N}$$ \hspace{1cm} (4)

where $|+\rangle = (|0\rangle + |1\rangle)/\sqrt{2}$, and $|0\rangle, |1\rangle$ are eigenvectors of $Z$ with eigenvalues $\pm 1$. The unitary two-qubit operation $U_{ab}$ is a controlled $Z$ on qubits $a$ and $b$, i.e. $U_{ab} = |00\rangle \langle 00| + |01\rangle \langle 01| + |10\rangle \langle 10| - |11\rangle \langle 11|$. We note that thesees unitary two-qubit operations commute with each other. Therefore, we can adopt different orders of the sequence of $U_{ab}$ to the initial state $|+\rangle^{\otimes N}$ and yield the same graph state $|G\rangle$. This property is the key point in our following proof.

As discussed above, a disconnected graph can be viewed as a collection of several separate connected subgraphs. Therefore, a disconnected graph state is just a product state of the corresponding connected subgraph states. Without loss of generality, it is sufficient for us to consider only the connected graph states here. The entanglement structure in multi-qubit entangled states is much more complex than the situation of two-qubit entangled states. For pure states of $N$ qubits, there are different levels of genuine $k$-qubit entanglement, $2 \leq k \leq N$, which is shared among all the $k$ qubits.

In Refs. [20], Hein et al show that there is no 2-qubit entanglement between any two qubits in general $N$-vertex connected graph states with $N \geq 3$ by examining the properties of reduced density matrices. However, there is no exact results about general genuine $k$-qubit entanglement for $3 \leq k \leq N - 1$. One reason is that unlike 2-qubit entanglement entanglement between 2 and $N$, there are few well defined genuine multi-qubit entanglement measures [21, 22, 23, 24, 25, 26, 27, 28, 29]. especially for general multi-qubit mixed states. For a natural entanglement measure, it should satisfy several necessary conditions, such as invariant under local unitary operations, vanish for separable states, and decrease on average under LOCC. In the following, using the operational definition of graph states and the postulates of entanglement measures, we first prove that genuine three-qubit entanglement vanish in connected graph states of four qubits. Then we will generalize our results to arbitrary genuine $k$-qubit entanglement.

III. GENUINE THREE-QUBIT ENTANGLEMENT IN GRAPH STATES

In this section, we will investigate genuine three-qubit entanglement among every three qubits in connected graph states by adopting the measure of square root of CKW tangle [30].

![FIG. 1: Six classes of four vertices connected graphs that are nonequivalent under graph isomorphisms.](image)

**Lemma 1:** Genuine three-qubit entanglement vanishes in connected graph states of four qubits.

**Proof:** There are six classes of four vertices connected graphs that are nonequivalent under graph isomorphisms as depicted in Fig. (1). For each graph state $|G\rangle_{1234}$, we can write the reduced density matrix $\rho_{ijk}$ of every three qubit $i,j,k = 1, 2, 3, 4$. By exploiting some skills [20, 21, 22, 23, 24, 25, 26, 27, 28, 29], it is easy for us to construct a special pure states decomposition of $\rho_{ijk}$ as $\rho_{ijk} = \sum_{i,j} |\phi_i\rangle \langle \phi_i|$, and the square root of CKW tangle $\tau(|\phi_i\rangle \langle \phi_i|) = 0$. For example, in the graph state $|G\rangle_{1234}$ corresponding to Fig. 1. (d), $\rho_{123} = \frac{1}{2}(|\phi_1\rangle \langle \phi_1| + |\phi_2\rangle \langle \phi_2|)$, where $|\phi_1\rangle = \frac{1}{2}(|+00\rangle + |+01\rangle + |+10\rangle - |+11\rangle)$ and $|\phi_2\rangle = \frac{1}{2}(|-00\rangle + |+01\rangle - |+10\rangle - |+11\rangle)$. The special pure states decomposition for $\rho_{123}$ is $\rho_{123} = \sum_{i=1}^4 |\phi_i\rangle \langle \phi_i|$, where $(|\phi_1\rangle, |\phi_2\rangle, |\phi_3\rangle, |\phi_4\rangle)^T = U(|\phi_1\rangle, |\phi_2\rangle)$, and $U$ is a left-unitary matrix [30] as

$$U = \frac{1}{\sqrt{2(1 + |\beta|^2)}} \begin{pmatrix} 1 & \beta \\ \beta & 1 \\ 1 & -\beta \\ -\beta & 1 \end{pmatrix}$$ \hspace{1cm} (5)

with $\beta^4 + 2\beta^2 + 1 = 0$. Thus we conclude that $\tau(\rho_{ijk}) = 0$ for every three qubits. $\square$

It should be emphasized that we only need to consider 2 equivalence classes under local Clifford (LC) operations [13]. One class includes Fig. 1. (a), (b), (c), and (f), the other class includes Fig. 1. (d) and (e). For these graph states, LC equivalence $\leftrightarrow$ local unitary (LU) equivalence, which do not change the entanglement properties [31, 32]. Based on lemma 1, we present the following theorem about genuine three-qubit entanglement in general connected graph states of more than three qubits.

**Theorem 1:** There is no genuine three-qubit entanglement in general connected graph states of more than three qubits.
Proof: We examine genuine three-qubit entanglement among every three qubits. Without loss of generality, we can denote these three qubits as 1, 2, and 3. According to whether the subgraph $G_{(1,2,3)} = \{(1,2,3), E_{(1,2,3)}\}$ is connected, there are two kinds of situations.

(a). The subgraph $G_{(1,2,3)}$ is connected. Since the number of qubits $N > 3$ and the corresponding graph is connected, there must exist one qubit 4 which make the subgraph $G_{(1,2,3,4)} = \{(1,2,3,4), E_{(1,2,3,4)}\}$ is also connected, i.e. it is one class of graph depicted in Fig 1. (a1). In the first step to obtain the graph state $|G\rangle$, we get the state $|\psi\rangle = \prod_{\{i,j\} \in E_{(1,2,3,4)}} U_{ij} |+\rangle^\otimes N$, where $|G_{(1,2,3,4)}\rangle = |G_{(1,2,3,4)}\rangle\rangle^\otimes N$ is the graph states of four qubits, which results in the subgraph $\psi$ being connected. From the subgraph $\psi$ related to qubit 1, 2 and 3 to $(a1)$. In the first step to obtain the graph state $|G\rangle = \prod_{\{i,j\} \in E_{(1,2,3,4)}} U_{ij} |+\rangle^\otimes N$, i.e. $|\psi\rangle$ denotes these three qubits as 1, 2, and 3. According to whether the subgraph $G_{(1,2,3,4,5)}$ is connected, there are two kinds of situations. (a2). In the second step, we apply unitary two-qubit operations related to qubit 1, 2 and 3 to $|\psi\rangle$. The effects of each block of operations $\prod_{\{i,j\} \in E_{(1,2,3,4)}} U_{ij}$ for $i \in V - \{1,2,3,4\}$ on $\rho_{123}$ can be characterized by the superoperator $\mathcal{E}(\rho_{123}) = \frac{1}{2} \mathcal{E}(\rho_{123}) + \frac{1}{2} (u_1 \otimes u_2 \otimes u_3) \rho_{123} (u_1 \otimes u_2 \otimes u_3)$, where $u_1, u_2, u_3 \in I/2$ or $Z$. It describes a certain local operation on qubit 1, 2 and 3. Since the square root of CKW tangle is an entanglement monotone function $\mathcal{E}$, we can get $\tau(\rho_{123}) = 0$ for $|\psi\rangle$. (a3). In the last step, we apply the remain unitary two-qubit operations independent on qubit 1, 2 and 3 to $|\psi\rangle$ and obtain the final graph state $|G\rangle = \prod_{\{i,j\} \in E_{(1,2,3,4)}} U_{ij} |\psi\rangle$. In this step, $\rho_{123}$ is unchanged. Therefore, we conclude that $\tau(\rho_{123}) = 0$ for $|G\rangle$.

(b) The subgraph $G_{(1,2,3)}$ is disconnected. In this situation, we first get $|\psi\rangle = \prod_{\{i,j\} \in E_{(1,2,3)}} U_{ij} |+\rangle^\otimes N$. Since $G_{(1,2,3)}$ is disconnected, it is obvious that $\tau(\rho_{123}) = 0$ for the state $|\psi\rangle$. The second step is $|\psi\rangle = \prod_{i \in V - \{1,2,3\}, j \in \{1,2,3\}, \{i,j\} \in E} U_{ij} |\psi\rangle$ and the last step is $|G\rangle = \prod_{i \in V - \{1,2,3\}, j \in \{1,2,3\}, \{i,j\} \in E} U_{ij} |\psi\rangle$. The effects of these two steps on $\rho_{123}$ are the same as the last two steps in the above situation (a). Therefore, we also obtain that $\tau(\rho_{123}) = 0$ in the state $|G\rangle$, and theorem 1 is proved. □

IV. GENERAL GENUINE K-QUBIT ENTANGLEMENT IN GRAPH STATES

Adopt the above idea based on the operational description of graph states and the postulates of entanglement measures, we could investigate the properties of general genuine k-qubit entanglement in graph states.

**Theorem 2:** Consider a connected graph states of N qubits, and let S be a group of m qubits, 2 ≤ m ≤ N − 1, the reduced density matrix $\rho_S$ is always separable for some bipartition $A|B$, where $B = S \setminus A$ and $A \subset S$ is the subset of vertices that connected to the outside $S$.

Proof: In the similar way as theorem 1, we denote the graph state

$$|G\rangle = U_{AA} U_{BB} U_{SS} U_{BB} U_{AA} |\psi\rangle^\otimes N$$

where $U_{XY} = \prod_{i \in X, j \in Y, \{i,j\} \in E} U_{ij}$. It is easy to check that for $U_{A|B} |\psi\rangle^\otimes N$, $\rho_S = \frac{1}{2^{|A|}} \mathbb{1}^{|A|} \otimes (|+\rangle^\otimes |B\rangle)$, and for $U_{A|B} |\psi\rangle^\otimes N$, $\rho_S = \frac{1}{2^{|A|}} \sum_{i_1,\ldots,i_4=0,1} (|i_1\cdots i_4\rangle \langle i_1\cdots i_4|)_A (|i_1\cdots i_4\rangle \langle i_1\cdots i_4|)_B$, which is separable for the bipartition $A|B$. Note that $U_{AA} U_{BB} U_{SS} U_{BB} U_{AA}$ will introduce only local operations for individual party $A$ and $B$. Therefore, in the graph state $|G\rangle$, the reduced density matrix $\rho_S$ is separable for some bipartitions. □

**Corollary 1:** All genuine k-qubit entanglement, 2 ≤ k ≤ N − 1, vanishes in general connected graph states of N qubits.

Proof: According to theorem 2, for any subset $S$ of 2 ≤ k ≤ N − 1 qubits, the reduced density matrix $\rho_S$ is separable for some bipartition, therefore any genuine k-qubit entanglement measure should be zero, which is one of the necessary conditions for entanglement measures. Thus we finish the proof of corollary 1. □

V. MAXIMATELY GENUINE MULTI-QUBIT ENTANGLED STATES

The connected graph states can not be written as a product form for any bipartition, and it is believed that connected graph states are genuine multi-qubit entangled states. Based on the results in corollary 1, we explicitly show that in connected graph states of N qubits, there is no genuine k-qubit entanglement for arbitrary 2 ≤ k ≤ N − 1. Moreover, it is easy to check that the reduced density matrix of each qubit is $I/2$. With these intuitions, we could naturally define the maximally genuine multi-qubit entangled states as

A pure state of N qubits $|\psi\rangle$ is maximally genuine N-qubit entangled if it satisfies: (1) There does not exist a bipartition such that $|\psi\rangle$ is product; (2) The reduced state of each qubit is maximally mixed, i.e. $\rho_i = Tr_{1,2,\cdots,i-1,i+1,\cdots,N} |\psi\rangle \langle \psi| = I/2$; (3) There is no genuine k-qubit entanglement, with 2 ≤ k ≤ N − 1.

If N = 2, the above definition will reduce to maximally two-qubit entangled states. We note that stronger and sligher different definitions of maximal multipartite entanglement appeared in Refs 38, 82. However, the criterions we propose above are from the viewpoint of different levels of entanglement in multi-qubit entangled states, and is strongly motivated by the important class of multi-qubit entangled states, i.e. graph states. The above condition 1 means that $|\psi\rangle$ is not separable. The condition 2 stems from the complementary relations in multi-qubit entangled states 82, 83, the fact that the reduced state of each qubit is maximally mixed implies...
that local information is minimum, i.e. maximum entanglement. The last condition is introduced according to different levels of entanglement structure in multi-qubit entangled states. For example, in general N-qubit GHZ states there is only genuine N-qubit entanglement, which is shared among all the N qubits. However, in general N-qubit W states, there are only two-qubit entanglement, i.e. shared only between pairs of qubits. In this sense, N-qubit GHZ states are maximally genuine N-qubit entangled states, while N-qubit W states are not. Here, we should note that the meaning of genuine is a little different from the one in Ref. [32].

The connected graph states of four qubits $|G_4\rangle$ is a kind of maximally genuine four-qubit entangled states. However, it not the only class of maximally genuine four-qubit entangled states. A generic pure state of four qubits can always be transformed to the normal form state by the determinant 1 SLOCC (stochastic local operations and classical communication) operations $[38, 39]$, $G_{abcd} = \frac{a+d}{2}(|0000\rangle + |1111\rangle) + \frac{a-d}{2}(|0011\rangle + |1100\rangle) + \frac{b+c}{2}(|0101\rangle + |1010\rangle) + \frac{b-c}{2}(|0110\rangle + |1001\rangle)$, where $a, b, c, d$ are complex parameters with nonnegative real part. Without loss of generality, we could assume $A = (a+d)/2$ is a positive real number, i.e. $A = x_1 = |A|$. We denote $B = (b+c)/2 = x_2 \exp(i\phi_2), C = (a-d)/2 = x_3 \exp(i\phi_3), D = (b-c)/2 = x_4 \exp(i\phi_4)$, with $x_2 = |B|$, $x_3 = |C|$, $x_4 = |D|$. We consider those $G_{abcd}$ that is a non-product state. The reduced density matrix of each qubit in $G_{abcd}$ is $I/2$. The square root of CKW tangle of the mixed states obtained by tracing out one qubit of $G_{abcd}$ is always equal to zero $[38]$. To ensure that pairwise entanglement also vanish in $G_{abcd}$, the parameters should fulfill the following conditions

\begin{align}
2x_1x_2|\cos \phi_2| &\leq x_1^2 + x_2^2 \\
2x_3x_4|\cos(\phi_2 - \phi_4)| &\leq x_3^2 + x_4^2 \\
2x_1x_4|\cos \phi_4| &\leq x_1^2 + x_4^2 \\
2x_2x_4|\cos(\phi_2 - \phi_3)| &\leq x_2^2 + x_4^2
\end{align}

Therefore, we can easily construct an explicit example of maximally genuine four-qubit entangled states

$$|MG_4\rangle = c(|0000\rangle + |1111\rangle) + \frac{i}{\sqrt{2}}c^2(|0011\rangle + |1100\rangle)$$

where $0 \leq c \leq \sqrt{1/2}$. It is obvious that $|MG_4\rangle$ is not always local unitary equivalent to any four-qubit connected graph state $|G_4\rangle$. This can be verified by noting that $Tr\rho_{23}^2$ is not always the same for $|MG_4\rangle$ and $|G_4\rangle$, where $\rho_{23}$ is the reduced density matrix of qubit 2 and 3.

VI. CONCLUSIONS AND DISCUSSIONS

In conclusion, we have investigate the entanglement properties of graph states by calculating different levels of genuine k-qubit entanglement. In this paper, via the operational definition of graph states, and using the postulates of entanglement measures, we construct explicit proofs that there are no genuine k-qubit entanglement, $2 \leq k \leq N-1$, in general connected graph states of N qubits. These results, together with intuitions about graph states, lead to a definition of maximally genuine multi-qubit entangled states. In addition, we find that the connected graph states of four qubits is only one class of maximally genuine multi-qubit entangled states. We present a kind of maximally genuine multi-qubit entangled states that are not always local unitary equivalent to connected graph states of four qubits. Our results demonstrate exactly that graph states are genuine multi-qubit entangled states. It may help us to gain some insight into the complex entanglement structure of multi-qubit entangled states from a new viewpoint of different levels of entanglement.
