Dedicated

(Dated: June 2, 2013)

Neutral pion transverse momentum spectra were measured in p+C and p+Pb collisions at \(P_{\text{SN}} = 173\) GeV at mid-rapidity (\(2.3 < \eta < 3.0\)) over the range \(0.7 < p_T < 35\) GeV/c. The spectra are compared to \(p_T\) spectra measured in Pb+Pb collisions at \(P_{\text{SN}} = 173\) GeV in the same experiment. For a wide range of Pb+Pb centralities (\(N_{\text{part}} < 300\)) the yield of \(\pi^0\) with \(p_T > 2\) GeV/c is larger than or consistent with the p+C or p+Pb yields scaled with the number of nucleon-nucleon collisions (\(N_{\text{coll}}\)), while for central Pb+Pb collisions with \(N_{\text{part}} > 350\) the \(\pi^0\) yield is suppressed.

PACS numbers: 25.75.Dw

The study of hadron production at high transverse momentum \(p_T\) is a sensitive tool to characterize the matter created in ultrarelativistic heavy-ion collisions, and in particular, to detect the possible formation of a quark-gluon plasma (QGP), i.e., a thermally excited phase in which quarks and gluons are the relevant degrees of free-
Particles at high $p_t$ result from quark and gluon scatterings with high momentum transfer ("hard scattering") which can be described by perturbative quantum chromodynamics (pQCD). The scattered quarks and gluons will traverse the created medium and fragment into the observable hadrons. High-$p_t$ particle production in nucleus-nucleus ($A + A$) collisions was predicted to be suppressed as a consequence of the energy loss of the scattered partons in the dense medium ("jet quenching"). Such suppression was observed by experiments at the Relativistic Heavy Ion Collider (RHIC) in central Au+Au and Cu+Cu collisions at a center-of-mass energy of up to $s_{NN} = 200$ GeV. Within jet-quenching models the suppression can be related to medium properties, such as the initial gluon density or the transport coefficient ($\tau_0$, $\varepsilon$).

A crucial test for the idea of parton energy loss in the hot and dense medium created in $A + A$ collisions is the measurement of the $p_t$ dependence of high-$p_t$ hadron production [$\pi$/$\propto$, $\eta$, $\eta'$, $\rho$, $\omega$]. In central $p + p$ collisions at the CERN SPS energy of $s_{NN} = 173$ GeV ($\langle p_{T}\rangle = 158$ A GeV/c) the initial energy density, as estimated from the measured transverse energy, is above the critical value $\varepsilon_c = 1$ GeV/fm$^3$ for the transition to the QGP. On the other hand, the initial gluon density and the lifetime of a deconfined phase produced at $s_{NN} = 173$ GeV will be significantly reduced as compared to RHIC energies. Results at SPS energies thereby provide a sensitive test of jet quenching model predictions.

Results on high-$p_t$ particle production in central $p + p$ and $ Pb + Pb$ collisions at the CERN SPS have already been published [1,2]. However, the interpretation of these data has been complicated by the lack of reference $p + p$ data to allow to quantify nuclear effects. Instead, parameterizations of $p + p$ data have been employed to search for nuclear effects [1,2], but with substantial systematic uncertainties. Moreover, hadron suppression due to parton energy loss might be corrected by an enhancement due to multiple soft scatterings of the incoming partons prior to the hard scattering process ("nuclear$k_T$-enhancement" or "\langev\ et c."). Measurements in $p + A$ and $A + A$ collisions at different $p_{T}$ suggest that such enhancement is significantly stronger at $p_{T}$ = 20 GeV than at $p_{T}$ = 200 GeV.

In the W A98 experiment $\pi^0$ yields were measured by detection of photons from the $\gamma \rightarrow \pi^0$ decay branch with a high-resolution lead-glass calorimeter. This detector was located 21.5 m downstream from the target and subtended the pseudorapidity range $2.3 < \eta < 3.0$. A 400 GeV/c proton beam from the CERN SPS was pioned on a beryllium production target to provide a $p + Pb$ secondary beam selected to have momentum of 160 GeV/c. The secondary beam consisted primarily of protons and pions with roughly equal content. Protons were identified with the use of two gas Cherenkov counters located upstream of the 1797 g/cm$^2$ $^{12}$C (495 g/cm$^2$ $^{208}$Pb) target. The W A98 minimum bias trigger condition required a m inimum amount of transverse energy ($E_T$) in the region $3 < \eta < 5.5$, measured with a sampling calorimeter with electromagnetic and hadronic sections. The measured $p + p$ minimum bias cross section $\sigma_{pb}$ for $p + C$ ($p + Pb$) of 193 mb (1422 mb) corresponds to 86% (81%) of the total geometric cross section. The number of analyzed $p + p$ minimum bias events was 1.86 (18) $p + Pb$ events.

Neutral pion yields were determined statistically by counting photon pairs with invariant mass in the $\pi^0$ mass range after subtraction of the normalized background from uncorrelated pairs. The shape of this background was determined by modeling photons from di-electron events. Only photon pairs with an energy asymmetry $E_1\leq E_2$ < 0.7 were used in the analysis. A correction for geometrical acceptance and reconstruction efficiency was applied to the raw $\pi^0$ yields. The reconstruction efficiency takes into account the loss of $\pi^0$ due to the photon identity and energy asymmetry cuts. It also models the $\pi^0$ yield for the $p + C$ shift that results from the same energy resolution of the lead-glass calorimeter convoluted with the steeply falling $p_T$ spectrum. Events of overlapping showers in the calorimeters, which were in part in central $p + Pb$ collisions, are negligible in $p + C$ and $p + Pb$ collisions. The dominant systematic uncertainties are listed in Table 3. The systematic uncertainties of the peak extraction, acceptance correction, and efficiency correction are approximately independent of $p_T$. The energy scale of the calorimeter was corrected by comparison of the measured $p_T$-dependent $\pi^0$ peak positions with GEANT simulations. The estimated uncertainty of 15% on the energy scale leads to an uncertainty on the $\pi^0$ yields that increases with $p_T$.

The spectra of the invariant $\pi^0$ yields in $p + C$ and $p + Pb$ collisions at $s_{NN} = 173$ GeV are shown in Fig. 1.
demonstrate that pQCD calculations cannot be used as a reliable reference at CERN SPS energies. The inset of Fig. 4 shows that the $^0$ yields per nucleon-nucleon collision measured in p+C are in good agreement with a parametrization of $^0$ spectra in p+p from Baltz et al. [23] that has been employed to study nuclear e effects in Pb+Pb collisions [13].

Nuclear e effects in $^0$ production can be quantified with the nuclear modification factor defined as

$$R_{AA}^0 = \frac{N_{coll}^d}{N_{part}^{10}N_{coll}^d}$$

In the absence of nuclear e effects $R_{AA}^0$ is expected to be unity for $p_t > 2$ GeV/c where hard scattering is expected to dominate particle production. $N_{coll}$ was determined with a Glauber Monte Carlo calculation using an inelastic nucleon-nucleon cross section of $N_{inel} = 31.8 \pm 2$ mb [24]. The same Glauber calculation was used to extract $N_{coll}$ values in Pb+Pb collisions. In the Glauber calculation the transverse energy $E_T$ was modeled by sampling a negative binomial distribution to determine the $E_T$ contribution of each participating nucleon [24]. The bias due to the trigger selection on the measured $E_T$ was taken into account. For minimum bias p+C and p+Pb collisions, values of $N_{coll}$ were 1.7 \pm 0.2 and $N_{coll}^{p+Pb}$ was $3 \pm 0.4$ were obtained.

The $N_{coll}$ values for Pb+Pb collisions were determined by applying cuts to the simulated $E_T$ that corresponded to the same fraction of $N_{part}^{PB}$ as the cuts applied to the measured $E_T$. These $N_{coll}$ values are listed in Table I and agree with systematics uncertainties with those of Ref. [16] that were determined with the VENUS 4.12 event generator in which $N_{inel} = 29 \pm 3$ mb was used. With the large acceptance of the WA98 $E_T$ measurement, and good description of the $E_T$ distribution, including uctuations [14], a centrality class corresponding to the 1% most central Pb+Pb collisions could be defined to access very large $N_{coll}$ values.

The transition between the minimum bias and the HEP sample occurs at $p_t = 1.7$ GeV/c. The p+C spectrum is compared to a next-to-leading-order (NLO) pQCD calculation for p+p at the same energy [23]. The calculation was performed with the CTEQ6M parton distribution functions and the Kniehl-Kam et al. (KKP) set of fragmentation functions [23] with renormalization and factorization scales set to be the same at $p_t = 2$, $p_t$ or $2p_t$. For comparison with the p+C data the pQCD calculations have been scaled by the average number of nucleon-nucleon collisions in p+C. The pQCD calculation shows a large uncertainty related to the arbitrary choice of scale. It has been suggested that the NLO perturbative expansion is not sufficient at low energies and that threshold resummation corrections must be taken into account [23]. The large theoretical uncertainties demonstrate that pQCD calculations cannot be used as

The p+Pb $^0$ spectrum appears to be softer than the p+C spectrum (see Fig. 4). The ratio of the Ncoll-normalized p+Pb and p+C spectra is shown in Fig. 4. At low $p_T$ (1 GeV/c) the ratio is consistent with scaling with the number of participating nucleons ($N_{part}^{p+Pb}$).
The $N_{\text{coll}}$-normalized ratio of $^0_\pi$ yields in $p+Pb$ and $p+C$ collisions. The box at $R_{pPb}^{p+Pb}$ 0.9 represents the expectation for the case of scaling with $N_{\text{part}}$ rather than $N_{\text{coll}}$. The box at unity indicates the $N_{\text{coll}}$ systematic uncertainty. The error bars represent the systematic uncertainties of the statistical and remaining systematic uncertainties. The energy scale uncertainty was assumed to cancel.

**FIG. 2:**

The centralities of the average $R_{AA}^0$ yield in $p+Pb$ and $p+C$ collisions. The box at $R_{pPb}^{p+Pb}$ 0.9 represents the expectation for the case of scaling with $N_{\text{part}}$ rather than $N_{\text{coll}}$. The box at unity indicates the $N_{\text{coll}}$ systematic uncertainty. The error bars represent the quadratic sum of the statistical and remaining systematic uncertainties. The $N_{\text{part}}$ values for the full points were shifted by ±5 for better visibility.

![Image 2](image2.png)

**FIG. 3:**

$R_{AA}^0$ in $p+Pb$ collisions at $p_{T}=17.3$ GeV for three centrality classes using $p+C$ or $p+Pb$ spectra as a reference. The boxes around unity reflect the systematic uncertainties related to $N_{\text{coll}}$.

![Image 3](image3.png)

**FIG. 4:**

Centralities of the average $R_{AA}^0$ for $2 < p_T < 2.5$ GeV/c and $2.5 < p_T < 3$ GeV/c is shown in Fig. 4. The $^0_\pi$ yields in $p+Pb$ in these $p_T$ ranges are not suppressed for $N_{\text{part}} < 300$ ($R_{AA}^0 > 1$). For more central $p+Pb$ collisions $R_{AA}^0$ decreases with centrality indicating significant suppression of the high $p_T$ yield. The apparent lack of suppression, or enhancement even, for $N_{\text{part}} > 300$ may be due to competing effects of suppression due to parton energy loss and nuclear $k_T$-enhancement.

In summary, $^0_\pi$ spectra were measured in minimum bias $p+C$ and $p+Pb$ collisions at $p_{T}=17.3$ GeV in the range $0.7 < p_T < 3.5$ GeV/c. Based on these spectra, the nuclear modification factors $R_{AA}^0$ for $p+Pb$ collisions at CERN SPS energies could be determined using a measured $p+A$ reference. In very central $p+Pb$ collisions (0% of $p^+p$) a significant suppression of the high-$p_T$ neutral pions was observed ($R_{AA}^0 < 0.5$). The pion suppression reported here, together with the results at higher energies from RHIC, constrain jet-quenching models and may help clarify the behavior of the energy loss of partons in strongly interacting matter.
We would like to thank the CERN-SPS accelerator crew for the excellent beam provided and the Laboratoire National Satu- 
ratre for the loan of the magnet Goliath. We thank W. Vogelsang for providing the QCD calculation shown in this paper. This work was sup-
ported jointly by the German BM BF, DFG, and the Hein-holtz-Gemeinschaft (V1VH-146), the U.S. DOE, the Swedish NFR, the Dutch Stichting FOM, the Swiss National Fund, the Humboldt Foundation, the Stiftung für deutsch-polnische Zusammenarbeit, the Department of Atomic Energy, the Department of Science and Technology and the University Grants Commission of the Government of India, the Indo-FRG Exchange Programme, the PPE division of CERN, the NTAS under contract INTAS-97-0158, the Polish KBN under the grant 2P03B16815, the Grant-in-Aid for Scientific Research (Specially Promoted Research & International Scientific Research) of the Ministry of Education, Science, Sports and Culture, JSPS Research Fellowships for Young Scientists, the University of Tsukuba Special Research Projects, and ORISE. ORNL is managed by UT-Battelle, LLC, for the U.S. Department of Energy under contract DE-AC05-00OR22725.
