Abstract

We have measured the ratio \( \sigma(e^+e^- \rightarrow \pi^+\pi^-\gamma)/\sigma(e^+e^- \rightarrow \mu^+\mu^-\gamma) \), with the KLOE detector at DAΦNE for a total integrated luminosity of \( \sim 240 \text{ pb}^{-1} \). From this ratio we obtain the cross section \( \sigma(e^+e^- \rightarrow \pi^+\pi^-) \). From the cross section we determine the pion form factor \( |F_\pi|^2 \) and the two-pion contribution to the muon anomaly \( a_\mu \) for \( 0.592 < M_{\pi\pi} < 0.975 \text{ GeV} \), \( \Delta^{\pi\pi}a_\mu = (385.1 \pm 1.1_{\text{stat}} \pm 2.7_{\text{sys+theo}}) \times 10^{-10} \). This result confirms the current discrepancy between the Standard Model calculation and the experimental measurement of the muon anomaly.

Key words: e^+e^- collisions, Initial state radiation, Pion form factor, Muon anomaly
1 Introduction

Measurements of the muon magnetic anomaly $a_\mu = (g_\mu - 2)/2$ performed at the Brookhaven Laboratory have reached an accuracy of $0.54 \text{ ppm}$: $a_\mu = (11659208.9 \pm 6.3) \times 10^{-10}$ [1, 2]. The quoted value differs from Standard Model estimates by 3.2–3.6 standard deviations [3–6]$. The difference between measurement and calculations is of great interest since it could be a signal of New Physics. The authors of Ref. 8 have proposed an interpretation in terms of Supersymmetry, which can be probed at the Large Hadron Collider. Another proposal suggests the existence of a light vector boson in the Dark Matter sector, coupled with ordinary fermions through photon exchange, which is not excluded by present low energy tests of the Standard Model [9, 10]. A new round of measurements of $a_\mu$ is expected at Fermilab [11] and J-PARC [12], with the aim of considerably reducing the experimental error. To fully exploit the significance of improved measurements of $a_\mu$ it is important to confirm the present estimate of the hadronic corrections (see below) and possibly to decrease the corresponding error.

The main source of uncertainty in the Standard Model estimates of $a_\mu$ [3, 4] is due to hadronic loop contributions which are not calculable in perturbative QCD. To lowest order, the hadronic contribution $\Delta^{h,lo}a_\mu$, can be obtained from a dispersion integral [13, 14] over the “bare” cross section $\sigma^0(e^+e^- \rightarrow \text{hadrons}(\gamma))$. $\sigma^0$ is obtained from the physical cross section, inclusive of final state radiation, removing vacuum polarization, VP, effects and contributions due to additional photon emission in the initial state. The leading-order hadronic contribution is $\sim 690 \times 10^{-10}$, the precise value depending on the authors’ different averaging procedures, as discussed in Refs. 3–6. The $e^+e^- \rightarrow \pi^+\pi^-(\gamma)$ process contributes approximately 75% of the $\Delta^{h,lo}a_\mu$ value and accounts for about 40% of its uncertainty.

In the following, we discuss the measurement of the cross sections as a function of the $\mu^+\mu^-$ and $\pi^+\pi^-$ invariant masses $M_{\mu\mu}$ and $M_{\pi\pi}$:

\[ \frac{d\sigma(e^+e^- \rightarrow \mu^+\mu^-\gamma)}{ds_\mu} \text{ and } \frac{d\sigma(e^+e^- \rightarrow \pi^+\pi^-\gamma)}{ds_\pi} \]

with $s_\mu = M_{\mu\mu}^2$, $s_\pi = M_{\pi\pi}^2$, to be used for the determination of $\sigma^0(e^+e^- \rightarrow \pi^+\pi^-)$. From the latter we obtain the two-pion contribution to the anomaly, $\Delta^{h,lo}a_\mu$ and the pion form factor $|F_\pi|^2$ for comparison to other results.

$^1$ A recent evaluation [7] finds a difference between 4.7 and 4.9 standard deviations.
2 Measurement of $\sigma(\pi^+\pi^-)$ at DAΦNE

The KLOE detector operates at DAΦNE, the Frascati $\phi$-factory, an $e^+e^-$ collider running at fixed energy, $W = \sqrt{s} \sim 1020$ MeV, the $\phi$ meson mass. Initial state radiation (ISR) provides a means to produce $\pi^+\pi^-$ pairs of variable $s_\pi$. Counting $\pi^+\pi^-\gamma$ events leads to a measurement of $d\sigma(e^+e^- \rightarrow \pi^+\pi^-\gamma)/ds_\pi$ if the integrated luminosity is known, from which $\sigma(e^+e^- \rightarrow \pi^+\pi^-)$ can be extracted. We have published three measurements [15–17] of $\sigma(e^+e^- \rightarrow \pi^+\pi^-)$ for $0.1 < M_{\pi\pi}^2 < 0.95$ GeV$^2$, with results consistent within errors and a combined fractional uncertainty of about 1%. The luminosity was obtained by counting Bhabha scattering events and using the QED value of the corresponding cross section. To lowest order, the pion form factor is defined by:

$$\langle \pi^+\pi^- | J_{\mu}^{em}(\pi) | 0 \rangle = (p_{\pi^+} - p_{\pi^-})_\mu \times F_\pi \left( s_\pi = (p_{\pi^+} + p_{\pi^-})^2 \right).$$

(1)

where $p_{\pi^+}, p_{\pi^-}$ are the momenta of $\pi^+$ and $\pi^-$. The differential cross section for $e^+e^- \rightarrow \pi^+\pi^-\gamma$ due to the ISR amplitude of Fig. 1 is related to the dipion cross section $\sigma_{\pi\pi} \equiv \sigma(e^+e^- \rightarrow \pi^+\pi^-\gamma)$ [18]:

$$s \frac{d\sigma(\pi^+\pi^-\gamma)}{ds_\pi} \bigg|_{ISR} = \sigma_{\pi\pi}(s_\pi) \ H(s_\pi, s),$$

(2)

where the radiator function $H$ is computed from QED with complete NLO corrections [19–23] and depends on the $e^+e^-$ center-of-mass energy squared $s$. $\sigma_{\pi\pi}$ obtained from Eq. 2 requires accounting for final state radiation (FSR) in Fig. 1. In the following we only use events where the photon is emitted at small angles, as discussed in detail in Refs. 16, 17. The cross section for $e^+e^- \rightarrow \pi^+\pi^-\gamma$ is proportional to the two-photon $e^+e^-$ annihilation cross section, which diverges, at lowest order, for the photon angle going to zero. This is not the case for the FSR contribution. Our choice results in a large enhancement of the ISR with respect to the FSR contribution.

Equation 2 is also valid for $e^+e^- \rightarrow \mu^+\mu^-\gamma$ and $e^+e^- \rightarrow \mu^+\mu^-$ with the same radiator function $H$. We can therefore determine $\sigma_{\pi\pi}$ from the ratio of the $\pi^+\pi^-\gamma$ and $\mu^+\mu^-\gamma$ differential cross sections for the same value of the dipion
and dimuon invariant mass (see also Refs. 24, 25). For ISR events we have:

\[ \sigma^0(\pi^+\pi^-, s') = \frac{d\sigma(\pi^+\pi^-\gamma, \text{ISR})/ds'}{d\sigma(\mu^+\mu^-\gamma, \text{ISR})/ds'} \times \sigma^0(e^+e^- \rightarrow \mu^+\mu^-, s'). \] (3)

where \( s' = s_\pi = s_\mu \).

Final state photon emission for both the \( \pi^+\pi^-\gamma \) and \( \mu^+\mu^-\gamma \) channels slightly modifies Eq. 3. These corrections are included in our analysis [26].

From the bare cross section \( \sigma^0_{\pi\pi} \) we obtain the pion form factor:

\[ |F_\pi(s')|^2 = \frac{3}{\pi} \frac{s'}{\alpha^2 \beta_\pi^2} \sigma^0_{\pi\pi(\gamma)}(s')(1 + \delta_{VP})(1 - \eta_\pi(s')) \] (4)

where \( \delta_{VP} \) is the VP correction [27] and \( \eta_\pi \) accounts for FSR radiation assuming point-like pions [28].

The advantages of the ratio method are:

(1) the \( H \) function does not appear in Eq. 3. Therefore the measurement of \( \sigma_{\pi\pi} \) is not affected by the related systematic uncertainty of 0.5% [19];
(2) using the same data sample for the \( \pi^+\pi^-\gamma \) and \( \mu^+\mu^-\gamma \) events, there is no need for luminosity measurements;
(3) vacuum polarization corrections and most other radiative corrections cancel in the ratio;
(4) using the same fiducial volume, acceptance corrections to the \( \pi^+\pi^-\gamma \) and \( \mu^+\mu^-\gamma \) spectra almost cancel resulting in a small systematic uncertainty.

In the following we describe the measurement of \( d\sigma_{\mu\mu\gamma}/ds_\mu \) using the same data as those to measure \( d\sigma_{\pi\pi\gamma}/ds_\pi \) [16].

### 3 Measurement of the \( e^+e^- \rightarrow \mu^+\mu^-\gamma \) cross section

The data sample corresponds to an integrated luminosity of 239.2 pb\(^{-1}\) collected in 2002, with low machine background and stable DAΦNE conditions. We also recorded events without offline filters with a downscaled trigger, providing control samples for evaluating efficiencies.
3.1 The KLOE Detector

The KLOE detector consists of a cylindrical drift chamber (DC) [29] and a lead–scintillating fibers electromagnetic calorimeter (EMC) [30]. The DC has a momentum resolution of $\sigma_{p_\perp}/p_\perp \sim 0.4\%$ for tracks with polar angle $\theta > 45^\circ$. Track points are measured in the DC with a resolution in $r$-$\phi$ of about 0.15 mm and about 2 mm in $z$. The EMC has an energy resolution of $\sigma_E/E \sim 5.7%/\sqrt{E} (\text{GeV})$ and an excellent time resolution of $\sigma_t \sim 57 \text{ ps}/\sqrt{E} (\text{GeV}) \oplus 100 \text{ ps}$. A cross section of the detector in the $y$, $z$ plane is shown in Fig. 2. A superconducting coil provides an axial magnetic field of 0.52 T along the bisector of the colliding beam directions. The bisector is taken as the $z$ axis of our coordinate system. The $x$ axis is horizontal, pointing to the center of the collider rings and the $y$ axis is vertical, directed upwards. The trigger [31] uses both EMC and DC information. Events used in this analysis are triggered by two energy deposits larger than 50 MeV in two sectors of the barrel calorimeter.

3.2 Identification of $e^+e^- \rightarrow \mu^+\mu^-\gamma$ events

The signature for $e^+e^- \rightarrow \mu^+\mu^-\gamma$ events with the photon emitted at small angle is just two tracks of opposite curvature, the photon being lost in the beam pipe. Four types of events contribute to the above signature: 1: $e^+e^- \rightarrow \mu^+\mu^-\gamma$, 2: $e^+e^- \rightarrow \pi^+\pi^-\gamma$, 3: $e^+e^- \rightarrow e^+e^-\gamma$, and 4: $e^+e^- \rightarrow \pi^+\pi^-\pi^0$. The four reactions can be distinguished kinematically. From the overdetermined system
of kinematical constraints of the reaction $e^+e^- \rightarrow x^+x^-\gamma$, we can compute
the common mass ($m_x$) of particles $x^+$ and $x^-$. The four processes give $m_x = m_\mu$, $m_\pi$, $m_e$ and $> m_\pi$. Additional separation between electrons and pions or muons is obtained from a particle identification (PID) estimator for each track, $L_{\pm}$, which uses time-of-flight information and the value and shape of
the energy deposit of each charged particle in the calorimeter [16]. Figure 2
shows the fiducial volume we use for muons and unobserved photons which is
identical to that used in Ref. 16 for $e^+e^\rightarrow\pi^+\pi^-\gamma$.

We list below the requirements for $\mu\mu\gamma$ event acceptance.

(1) Events must have at least two tracks of opposite sign, with origin at
the interaction point and polar angle satisfying $50^\circ < \theta < 130^\circ$. The
reconstructed momenta must satisfy $p_\perp > 160$ MeV or $|p_z| > 90$ MeV, to
ensure good reconstruction and efficiency.

(2) The polar angle $\theta_{\mu\mu}$ of the dimuon system obtained from the momentum
of the two tracks ($p_{\mu\mu} = p_+ + p_-$) must satisfy $|\cos \theta_{\mu\mu}| > \cos(15^\circ)$.

(3) Events with both tracks having $L_{\pm} < 0$ are identified as $ee\gamma$ events and
rejected. The loss due to this cut is less than 0.05%, as evaluated with
$\mu\mu$ samples, obtained from both data and Monte Carlo.

(4) The computed mass for the two observed particles must satisfy $80 < m_x < 115$ MeV.

About $8.9 \times 10^5 \mu\mu\gamma$ events pass these criteria, while $34.9 \times 10^5$ events are
selected as $\pi\pi\gamma$ [16]. Figure 3 shows the $m_x$ distribution together with the
accepted regions for $\mu\mu\gamma$ and $\pi\pi\gamma$ events.

![Fig. 3. Data $\mu\mu\gamma$ and $\pi\pi\gamma$ regions in the $m_x$ spectrum. The $\mu\mu\gamma$ and $\pi\pi\gamma$ accepted regions are shown in blue and green. A residual contamination of $\pi^+\pi^-\pi^0$ events is visible at high $m_x$ values.](image-url)
3.3 Background estimates

Residual $\pi^+\pi^-\gamma$, $\pi^+\pi^-\pi^0$ and $e^+e^-\gamma$ backgrounds are evaluated by fitting the observed $m_x$ spectrum with a superposition of Monte Carlo simulation (MC) distributions describing signal and $\pi^+\pi^-\gamma$, $\pi^+\pi^-\pi^0$ backgrounds, and a distribution obtained from data for the $e^+e^-\gamma$ background. The normalized contributions from signal and backgrounds are free parameters of the fit, performed for 30 intervals in $M_{\mu\mu}^2$ of 0.02 GeV$^2$ width for $0.35 < M_{\mu\mu}^2 < 0.95$ GeV$^2$.

In the $\rho$ mass region, the fractional $\pi^+\pi^-\gamma$ yield in the $\mu\mu\gamma$ acceptance region is about 15% of the sample. To improve the MC description of the low energy $m_x$ tail of $\pi^+\pi^-\gamma$ events in the muon peak, Fig. 3, we apply a data/MC resolution correction, function of $s_{\mu}$. This correction is evaluated from a high purity sample of $\phi \rightarrow \pi^+\pi^-\pi^0$ events, with the same track requirements used for $\mu\mu\gamma$ events, requiring in addition two photons with an invariant mass compatible with the $\pi^0$ mass, both for data and MC [26]. Figure 4 shows the comparison between data and MC before and after the resolution correction.

![Data and MC $m_x$ distributions for the $\pi^+\pi^-\pi^0$ control sample, before (upper) and after (lower) the resolution correction.](image)

The $\pi^+\pi^-\gamma$, $\pi^+\pi^-\pi^0$ and $e^+e^-\gamma$ background fractions as obtained by the fitting procedure are given in Table 1 at three $s_{\mu}$ values. The estimated $\pi^+\pi^-\pi^0$ fraction obtained from the fit procedure is consistent with the one expected from the theoretical cross section. Contributions from $e^+e^- \rightarrow e^+e^-\mu^+\mu^-$ and $e^+e^- \rightarrow e^+e^-\pi^+\pi^-$ processes are evaluated using the Nextcalibur [32] and Ekhara [33] MC generators. After analysis cuts, the $e^+e^- \rightarrow e^+e^-\pi^+\pi^-$ process is found to be negligible, while the $e^+e^- \rightarrow e^+e^-\mu^+\mu^-$ background contribution is between 0.6% and 0.1%, in the low $M_{\mu\mu}^2$ region and is subtracted from the data spectrum [26].

8
Systematic errors in the background subtraction include: (i) Errors on the parameters from the fit procedure: these decrease monotonically from 0.7% to 0.1% with respect to $s_\mu$; (ii) The uncertainty on the data/MC resolution corrections: about 1% in the $\rho$ mass region, smaller at higher $s_\mu$, negligible at lower $s_\mu$ values; (iii) The uncertainty on the $e^+e^-\rightarrow e^+e^-\mu^+\mu^-$ process: about 0.4% at low $s_\mu$ values, rapidly falling to 0.1% for $s_\mu > 0.5$ GeV$^2$. The correctness of the background estimate has been checked by two independent methods.

(1) We perform a kinematic fit of the two-track events assuming it is a $\mu\mu\gamma$ state. The $\chi^2$ value obtained is used as a discriminant variable, instead of $m_x$, in the fitting procedure described above.

(2) We improve the $\pi$-$\mu$ separation by use of $m_x$, applying a quality cut on the helix fit for both tracks. This cut reduces the dipion background in the dimuon signal region by more than a factor of two.

The background fractions obtained for both cases are in good agreement with the standard procedure [26].

### 3.4 Efficiencies, acceptance and systematic errors

The MC generator Phokhara, including next-to-leading-order ISR as well as FSR corrections [22] has been inserted in the standard KLOE MC Geanfi [34]. We compared MC efficiencies with efficiencies obtained from data control samples, and studied two major effects: the EMC response to muons clusters and the muon DC tracking efficiency.

**EMC response.** From a subsample of $\mu\mu\gamma$ events with both tracks fitted, the efficiency to find at least a cluster with $L > 0$ is found to be equal to one within $10^{-4}$. The trigger efficiency is obtained from a sample of $\mu\mu\gamma$ events where a single muon satisfies the trigger requirements. Then, the trigger response for the other muon is parametrized as a function of its momentum and direction. The efficiency as a function of $s_\mu$ is obtained using the MC event distribution and is equal to one within $5\cdot10^{-4}$.

**Tracking.** Using one muon to tag the presence of the other we find that the efficiency for a single muon track is about 99.6%, resulting in a combined
efficiency of about 99%, almost constant in $s_{\mu}$. The systematic error is evaluated varying the purity of the control sample and ranges from 0.3 to 0.6% as function of $s_{\mu}$.

**Acceptance and $m_x$.** Efficiencies for $m_x$ cuts and acceptance are evaluated from MC, corrected to reproduce data distributions. The systematic uncertainty due to the $m_x$ cut is obtained by moving the cut by about one sigma of the mass resolution and evaluating the difference in the $\mu\mu\gamma$ spectrum. We find a fractional difference of 0.4% (constant in $s_{\mu}$) which we take as systematic error. Systematic effects due to polar angle requirements for the muons, $50^\circ < \theta < 130^\circ$, and of dimuon, $|\cos\theta_{\mu\mu}| > \cos(15^\circ)$, are estimated by varying the angular acceptance by $1^\circ$ (more than two times the resolution on the polar angle of the muon tracks) around the nominal value. The systematic error ranges from 0.1 to 0.6%.

**Unfolding.** Due to the smoothness of the $\mu\mu\gamma$ spectrum and to the choice of bin width much larger than the mass resolution, resolution effects are corrected by Monte Carlo with negligible systematic error.

**Software Trigger.** A third level trigger is implemented to reduce the loss of events rejected as cosmic rays. Its efficiency for $\mu\mu\gamma$ events, evaluated from an unbiased downscaled sample, is consistent with one within $10^{-3}$ which is taken as systematic error.

4 Results

4.1 Evaluation of $\sigma(e^+ e^- \rightarrow \mu^+ \mu^- \gamma)$ and comparison with QED at NLO

The differential $\mu^+ \mu^- \gamma$ cross section is obtained from the observed event count $N_{\text{obs}}$ and background estimate $N_{\text{bkg}}$, as

$$
\frac{d\sigma_{\mu\mu\gamma}}{ds_{\mu}} = \frac{N_{\text{obs}} - N_{\text{bkg}}}{\Delta s_{\mu}} \frac{1}{\epsilon(s_{\mu}) L}.
$$

(5)

where $L$ is the integrated luminosity from Ref. 35 and $\epsilon(s_{\mu})$ the selection efficiency. Figure 5 top, shows the measured $\mu^+ \mu^- \gamma$ cross section compared with the QED calculations to NLO, using the MC code Phokhara [22]. Figure 5 bottom, shows the ratio between the two differential cross sections. The green band indicates the systematic uncertainty, experimental and theoretical, of the measured cross section. The average ratio, using only statistical errors, is $0.9981 \pm 0.0015$, showing good agreement within the quoted systematic uncertainties.
Fig. 5. Top. Comparison of data and MC results for $d\sigma_{\mu\gamma}/ds_\mu$. Bottom. Ratio of the two spectra. The green band shows the systematic error.

4.2 Determination of $\sigma(e^+e^- \rightarrow \pi^+\pi^-\gamma)$ from the $\pi^+\pi^-\gamma/\mu^+\mu^-\gamma$ ratio.

From the bin-by-bin ratio of our published $\pi^+\pi^-\gamma$ and the $\mu^+\mu^-\gamma$ differential cross sections described above, we obtain the bare cross section $\sigma^0_{\pi\pi(\gamma)}$ (inclusive of FSR, with VP effects removed) which is used in the dispersion integral for computing $\Delta_{\pi\pi}a_\mu$. Figure 6 shows the $\pi^+\pi^-\gamma$ and $\mu^+\mu^-\gamma$ event spectra after background subtraction and data/MC corrections. Figure 7 shows the

Fig. 6. Square invariant mass distributions of $\pi^+\pi^-\gamma$ (blue) and $\mu^+\mu^-\gamma$ (red) events after background subtraction and data/MC corrections.

bare cross section $\sigma^0_{\pi\pi(\gamma)}$. The pion form factor $|F_\pi|^2$ is then obtained using Eq. 4.

Table 4 gives our results for the bare cross section and the pion form factor. Only statistical errors are shown. Systematic uncertainties on $\sigma^0_{\pi\pi(\gamma)}$ and $|F_\pi|^2$ are given in Ref. 26. Most of them are smaller than the individual uncertainties on $\pi\pi\gamma$ and $\mu\mu\gamma$ due to correlation between the two measurements [26].
5 Evaluation of $\Delta^{\pi\pi}a_\mu$ and comparisons with other KLOE results

The dispersion integral for $\Delta^{\pi\pi}a_\mu$ is computed as the sum of the values for $\sigma^0_{\pi\pi(\gamma)}$ listed in Table 4 times the kernel $K(s)$, times $\Delta s = 0.01$ GeV$^2$:

$$\Delta^{\pi\pi}a_\mu = \frac{1}{4\pi^3} \int_{s_{\text{min}}}^{s_{\text{max}}} ds \sigma^0_{\pi\pi(\gamma)}(s) K(s),$$

(6)

where the kernel is given in Ref. 14. Equation 6 gives $\Delta^{\pi\pi}a_\mu = (385.1 \pm 1.1_{\text{stat}} \pm 2.6_{\text{exp}} \pm 0.8_{\text{th}}) \times 10^{-10}$ in the interval $0.35 < M^2_{\pi\pi} < 0.95$ GeV$^2$. For each bin contributing to the integral, statistical errors are combined in quadrature and systematic errors are added linearly. Contributions to the $\Delta^{\pi\pi}a_\mu$ systematic uncertainty are shown in Table 2. It is worth emphasizing that the use of the

Table 2
List of systematic errors on the $\Delta^{\pi\pi}a_\mu$ measurement. Many systematic effects on the individual $\pi\pi\gamma$ and $\mu\mu\gamma$ analyses cancel in the ratio.
\( \pi \pi \gamma \) to \( \mu \mu \gamma \) ratio results in a reduction of the total systematic error compared to the one published in Ref. 16 due to almost negligible theoretical uncertainty and correlations between the \( \pi \pi \gamma \) and \( \mu \mu \gamma \) measurements [26]:

**Background subtraction.** The systematic uncertainty is dominated by the data/MC resolution correction in the \( \mu \mu \gamma \) analysis (see Section 3.3). Other contributions from fitting function and residual background are correlated for \( \mu \mu \gamma \) and \( \pi \pi \gamma \) bringing the total systematic error to 0.6\% on \( \Delta \pi \pi a_\mu \).

**Geometrical and \( m_x \) acceptance.** The use of the same angular cuts for the \( \pi \pi \gamma \) and \( \mu \mu \gamma \) analyses yields a negligible acceptance correction in the ratio. The systematic uncertainty on \( m_x \) scale calibration is 0.2\% due to cancellations in the ratio.

**Tracking.** The tracking-efficiency corrections are very similar for pions and muons, leading to an overall correction in the ratio which ranges between 0.2\% for \( M^2_{\mu \mu} \) above 0.5 GeV\(^2\) to 0.5\% below it. The corresponding systematic uncertainty is conservatively estimated as 50\% of the correction value, fully bin-to-bin correlated, and translates to a 0.1\% systematic uncertainty on \( \Delta \pi \pi a_\mu \).

The entry “FSR correction” in Table 2 takes into account the uncertainty on possible additional photons in the unshifting procedure for pions [16] and on missing diagrams in Phokhara for \( \mu \mu \gamma \).

Figure 8 (top) shows the comparison between the present \( |F_\pi|^2 \) measurement and the previous KLOE [15] measurement, requiring the ISR photon to be reconstructed at large angle, inside the EMC barrel. Figure 8 (down) shows the fractional difference between the two measurements. They are done on independent data sets, with different running conditions (\( W = M_\phi \) here, \( W = 1 \) GeV in Ref. 15), and also with a different selection, that in turn imply independent systematic uncertainties. The two measurements are in very good agreement.

Table 3 summarizes the comparison between the two most recent KLOE published measurements and the present work on \( \Delta \pi \pi a_\mu \): the three results are in very good agreement.

### 6 Conclusions

We have measured the differential cross section \( d\sigma(e^+e^- \rightarrow \mu^+\mu^-\gamma)/dM^2_{\mu\mu} \) using events with initial state radiation photons emitted at small angle and inclusive of final state radiation. The measurement is in good agreement with QED to NLO prediction. We determined the pion form factor from the ratio...
Fig. 8. Left: the pion form factor obtained in this work, KLOE12 (crosses) and from the measurement with the photon at large angle, KLOE10 [15] (points). Right: fractional difference between the two $|F_\pi|^2$ measurements. The dark grey band is the statistical error from [15], the light grey band is the combined statistical and systematic uncertainty. In both figures, errors on crosses include combined statistical and systematic uncertainties.

Table 3
Comparison of $\Delta^{\pi\pi}a_\mu$ between our most recent measurements and the present work.

between the $d\sigma(e^+e^- \rightarrow \pi^+\pi^-\gamma)/dM_{\pi\pi}^2$ and $d\sigma(e^+e^- \rightarrow \mu^+\mu^-\gamma)/dM_{\mu\mu}^2$ cross sections, measured with the same data set. In this way, the radiator $H$ function is not used, the luminosity of the sample cancels out and the acceptance corrections compensate, resulting in an almost negligible systematic error.

This pion form factor determination is in very good agreement with previous KLOE results. We compute the $\pi^+\pi^-$ contribution to the muon anomaly in the interval $0.592 < M_{\pi\pi} < 0.975$ GeV to be:

$$\Delta^{\pi\pi}a_\mu = (385.1 \pm 1.1_{\text{stat}} \pm 2.6_{\text{sys\&exp}} \pm 0.8_{\text{sys\&th}}) \times 10^{-10},$$

with an experimental accuracy of 0.7% and a theoretical uncertainty at the 0.2% level.

This result, with comparable total experimental uncertainty and a theoretical error reduced by about 70% with respect to our previous results, confirms the
| $M^2_{\pi\pi}$ GeV$^2$ | $\sigma^{0}_{\pi\pi(\gamma)}$ nb | $|F_\pi|^2$ | $M^2_{\pi\pi}$ GeV$^2$ | $\sigma^{0}_{\pi\pi(\gamma)}$ nb | $|F_\pi|^2$ |

Acknowledgments

We would like to thank Henryk Czyż, Sergiy Ivashyn, Fred Jegerlehner, Johann Kühn, Guido Montagna, Fulvio Piccinini, Germán Rodrigo, Olga Shekhovtsova and Thomas Teubner for numerous useful discussions.

We thank the DAΦNE team for their efforts in maintaining low background running conditions and their collaboration during all data taking. We want to thank our technical staff: G. F. Fortugno and F. Sborzacchi for their dedication in ensuring efficient operation of the KLOE computing facilities; M. Anelli for his continuous attention to the gas system and detector safety; A. Balla, M. Gatta, G. Corradi and G. Papalino for electronics maintenance; M. Santoni, G. Paoluzzi and R. Rosellini for general detector support; C. Piscitelli for his help during major maintenance periods. This work was supported in part by the EU Integrated Infrastructure Initiative HadronPhysics Project under contract number RII3-CT-2004-506078; by the European Commission under the 7th Framework Programme through the ‘Research Infrastructures’ action of the ‘ Capacities’ Programme, Call: FP7-INFRASTRUCTURES-2008-1, Grant Agreement N. 227431; by the Polish National Science Centre through the Grants No. 0469/B/H03/2009/37, 03099/B/H03/2011/40, 2011/01/D/ST2/00748, 2011/03/N/ST2/02641, 2011/03/N/ST2/02652 and by the Foundation for Polish Science through the MPD programme and the project HOMING PLUS BIS/2011-4/3.
