(Received 27 April 2018; published 9 July 2018)

We present new relations for scattering amplitudes of color ordered gluons, massive quarks and scalars minimally coupled to gravity. Tree-level amplitudes of arbitrary matter and gluon multiplicities involving one graviton are reduced to partial amplitudes in QCD or scalar QCD. The obtained relations are a direct generalization of the recently found Einstein-Yang-Mills relations. The proof of the new relation employs a simple diagrammatic argument trading the graviton-matter couplings to an “upgrade” of a gluon coupling with a color-kinematic replacement rule enforced. The use of the Melia-Johansson-Ochirov color basis is a key element of the reduction. We comment on the generalization to multiple gravitons in the single color trace case.

DOI: 10.1103/PhysRevD.98.026011

I. INTRODUCTION

At the Lagrangian level Einstein’s theory of gravity and Yang-Mills (YM) gauge theory look quite different. Nonetheless, in a perturbative quantization on a flat space-time background intimate relations between their S-matrices exist, allowing one to express pure graviton scattering amplitudes through pure gluon scattering data. The first such connection are the Kawai-Lewellen-Tye relations \cite{1} derived from string theory. Later Bern, Carrasco and Johansson (BCJ) \cite{2–4} introduced a double-copy construction for graviton amplitudes from gluons. Here Lie-algebra like relations for the kinematic building blocks of gluon amplitudes were identified. The double copy technique may be used to generate loop-level integrands of gravitational theories from the simpler gauge-theory ones, this being the state-of-the-art method for higher loop computations in (super)-gravity. For the phenomenologically most relevant case of gravity minimally coupled to generic non-Abelian matter fields, i.e., QCD and scalar QCD with $N_f$ flavors minimally coupled to Einstein’s gravity. Again, we are able to present compact formulae to express single graviton-quark-gluon and graviton-scalar amplitudes in linear combinations of non-gravitational amplitudes. We comment on generalizations to higher graviton multiplicity in the discussion.

II. EINSTEIN-YANG MILLS

Gluon amplitudes may be color decomposed in various bases. A particular useful and minimal one, as it generalizes to QCD, is the Del Duca-Dixon-Maltoni (DDM) basis \cite{22} which organizes the $n$-gluon scattering amplitude in a basis of $(n - 2)!$ partial amplitudes

$$A_{\text{tree}} = \sum_{\sigma \in S_{n-2}} C(1, 2, \sigma) A^{\text{YM}}(1, 2, \sigma).$$

with the DDM factors

\[C(1, 2, \sigma, \ldots, \sigma_n) \equiv \mathring{f}^{a_1 a_2 a_3} b_3 \mathring{f}^{b_1 a_4 a_5} b_5 \ldots \mathring{f}^{b_{n-3} a_{n-2} a_1} \]

where $\mathring{f}^{abc} = i f^{abc}$ are the structure constants of the gauge group (our conventions are summarized in the Appendix).
Clearly, also for an EYM amplitude involving a single graviton and at leading order in gravitational coupling $\kappa$ (implying a color single trace structure) an identical color decomposition in the DDM basis may be applied

$$A_{n;1}^{\text{tree}} = \sum_{\sigma \in S_{n-1}} C(1, 2, \sigma) A_{\text{EYM}}(1, 2, \sigma; p),$$  

(2)

where the graviton leg $p$ is of course not participating in the color ordering. In [8] an intriguingly simple representation of this partial EYM-amplitude was derived from a string theory consideration

$$A_{\text{EYM}}(1, 2, \cdots, n; p) = \frac{\kappa}{2g} \sum_{i=0}^{n} (e_p \cdot X_i) A_{\text{YM}}(1, 2, \cdots, p, i, i+1, \cdots).$$  

(3)

Here the graviton polarization is written as $e^\mu_p = e^\sigma_p e_\sigma$. Moreover $X_{i} = \sum_{j=2} k_j$ denotes the region momentum. In a sense one half of the graviton has turned into a gluon evenly distributed amongst the $n$ gluons. Indeed the relation (3) immediately follows from the consistency of soft-limits. Both gravitons [23] and gluons [24] (resp. photons) obey universal factorization properties in the soft limit $p \to 0$

$$A_{\text{EYM}}(1, \cdots, n; p) \to 0 \sum_{i=0}^{n} (e_p \cdot k_i)^2 \frac{k_i \cdot p}{k_i \cdot p} A_{\text{YM}}(1, \cdots, n)$$

$$A_{\text{YM}}(\cdots, i, p, i+1, \cdots) \to 0 (e_p \cdot k_i - e_p \cdot k_{i+1}) \frac{k_i \cdot p}{k_{i+1} \cdot p} A_{\text{YM}}(1, \cdots, n).$$  

(4)

Our convention is that all external momenta are incoming. If one starts with (3) as an ansatz with an a priori undetermined $X_p$ one quickly arrives at the consistency conditions

$$X_1 - X_{i-1} = k_i, \quad X_2 = k_2 \quad \text{and} \quad X_n = -k_1$$  

(5)

upon taking $p$ soft. These relations are solved for the region momenta $X_i = \sum_{j=2} k_j$. In addition, the second consistency requirement of gauge invariance of (3), $e_\sigma^\mu \to p_\mu$, immediately yields the famous BCJ relation [2]

$$0 = \sum_{i=2}^{n} (p \cdot X_i) A_{\text{YM}}(1, 2, \cdots, i, p, i+1, \cdots).$$  

(6)

an essential ingredient of the double-copy construction [3,4]. So indeed (3) is entirely constrained by soft limits and gauge invariance.

### III. EINSTEIN-QCD

We now generalize (3) to QCD minimally coupled to gravity (EQCD). For this we first need to discuss the issue of color ordering in the presence of quarks and antiquarks in the fundamental representation $T^{ij}_{\mu}$ of the gauge group.

A very useful color basis for this was provided by Melia [25] and refined by Johansson-Ochirov [26], which we term the MJO-basis. An $n$-particle QCD amplitude consists of $k$ quark-antiquark pairs and $n - 2k$ gluons. Without loss of generality we take the flavors of all $k$ quark lines to be distinct. The primitive amplitudes in the MJO-basis are given by

$$\{A(\hat{1}, \hat{2}, \sigma) | \sigma \in \text{Dyck}_{k-1} \times \{\text{gluon insertions}\}_{n-2k}\}.$$  

Quarks and anti-quarks are marked with underscores or overscores, respectively. In the partial QCD amplitude $A(1, 2, \sigma)$ the permutation of the last $(n-2)$ arguments must form a Dyck word. The most intuitive definition is that a Dyck word corresponds to well formed bracket expressions with quarks preceded by opening and anti-quarks followed by closing brackets. In the MJO-basis a QCD amplitude may then be decomposed as

$$A_{n, k}^{\text{tree}} = \sum_{\sigma \in \text{MJO basis}} \chi(n, k) C(1, 2, \sigma) A_{\text{QCD}}(1, \hat{2}, \sigma),$$  

(7)

where $\chi(n, k) = (n-2)! \over k!$ is the dimension of the basis [26]. Using the bracket notation the color factors are given by

$$C(1, \hat{2}, \sigma) = (-1)^{k-1} [2|\sigma|1] \quad q \to |q| \otimes \Xi^i_{n-1}$$

$$g \to \Xi^a_i$$  

(8)

Here a level of “nestedness” $l$ has been introduced, it is the number of antiquarks minus the number of quarks to the left of the position in the Dyck word, and reflected in the tensor product structure. The important object $\Xi^i_l$ takes the form

$$\Xi^i_l = \sum_{s=1}^{l} \otimes 1 \otimes \ldots \otimes 1 \otimes T^{i} \otimes 1 \otimes \ldots \otimes 1 \otimes 1.$$  

(9)

The $\Xi^i_l$ form a representation of the gauge group Lie algebra $[\Xi^i_l, \Xi^j_l] = f^{abc} \Xi^c_l$. The explicit $C(1, \hat{2}, \sigma)$’s are sums of products of $k$ strings of generators $(T^{a_1} \ldots T^{a_k})_{ij}$ contracted over adjoint indices.

Clearly then, an Einstein-QCD amplitude at leading order in $\kappa$ (single color trace) involving a single-graviton enjoys a color decomposition in the MJO basis

$$A_{n, k;1}^{\text{tree}} = \sum_{\sigma \in \text{MJO basis}} \chi(n, k) C(1, \hat{2}, \sigma) A_{\text{EQCD}}(1, \hat{2}, \sigma; p).$$  

(10)

The central result of this letter is, that this partial EQCD-amplitude takes the form
\begin{equation}
A_{\text{EQCD}}(1, 2, \cdots, n; p) = \frac{k}{2g} \sum_{i=2}^{n} (\epsilon_p \cdot X_i) A_{\text{QCD}}(1, 2, \cdots, i, p, i+1, \cdots)
\end{equation}

in complete analogy to (3). A gauge transformation on leg \( p \) yields the BCJ relations (6) in QCD [26] which were proven in [27]. The relation (11) is also consistent with the soft limits as the soft behavior of gravitons and gluons is universal, i.e., (4) also holds for \( \{1, \ldots, n\} \) being (anti)quarks or gluons. These consistencies are strong evidence for the correctness of (11).

**IV. DIAGRAMMATIC PROOF**

In order to prove (11) consider the Feynman diagrammatic representation of the color dressed \( A_{n,k;1}^{\text{tree}} \) of (10). Starting from a pure QCD color dressed \( n \)-point amplitude \( A_{n,k}^{\text{tree}} \) the EQCD-amplitude may be obtained by attaching the graviton leg with data \( \epsilon^\mu p, \epsilon^\nu p, p^\rho \) to all propagators and vertices of the lower point QCD amplitude. The relevant vertices are depicted in Fig. 1, their mathematical expressions [28] are collected in the Appendix. Putting the graviton leg on-shell results in a subtle simplification. Let us look at the pure gluon-graviton vertices first. Here one observes a decomposition as

\[ A_{\text{tree}}(a \rightarrow b) = A_{\text{tree}}(a \rightarrow c) + A_{\text{tree}}(a \rightarrow d) \]

where the triangle attached to a leg indicates on-shellness. The dot on top of the gluon line denotes the appearance of the inverse massless propagator \( k^a_0 \) or \( k^b_0 \) which would be attached on the corresponding leg. Interestingly, the last term above represents an effective EYM vertex intimately related to the pure YM three-gluon vertex through a color-kinematical replacement rule

\[ f^{abc} \rightarrow -i \frac{\epsilon_p \cdot k_m}{2g} \delta_{mn} \]

which we demonstrate in the Appendix. In this relation the Ward identity has been used for the gluon legs \( a \) and \( b \) as they attach to invariant subamplitudes. Similarly the graviton-three-gluon vertex decomposes as

\[ f^{mpn} \rightarrow -i \frac{\epsilon_p \cdot k_m}{2g} \delta_{mn} \]

where again the dots on the top of the gluon lines denote inverse gluon propagators. Just as before the effective EYM vertex follows from the four gluon vertex upon color-kinematic replacement

\[ (T^p)_{jk} \rightarrow \frac{\epsilon_p \cdot k_m}{2g} \delta_{mn} \]

for generic indices \( m, n \) appearing in the color structure of the four gluon vertex. The final graviton dressing to be considered is the graviton-four-gluon vertex with an on-shell graviton leg. Here we observe a total decomposition into inverse propagator dressed legs only

\[ 026011-3 \]
Putting all these insights together we see that in the sum over all possible attachments of the on-shell graviton leg to the vertices and propagators of the lower point QCD amplitude, all the inverse propagator (dot on top the gluon leg) terms cancel out and the single-graviton EQCD amplitude may be evaluated by only considering the effective vertices of Eqs. (12)–(14), which are all generated by the color-kinematic replacement rule

\[ R_p := \left\{ (T^p)_{j1} \to \frac{K}{2g} (e_p \cdot k_j) \delta_{j1} \tilde{f}^{apb} \to \frac{K}{2g} (e_p \cdot k_a) \delta_{ab} \right\}, \]

from the sum over all attachments of a gluon to the same QCD amplitude. This insight entails immediately the relation for the colored amplitude

\[ A_{n,k,1}^{\text{tree}} = A_{n+1,k,0}^{\text{tree}} | R_p, \]

V. COLOR-KINEMATIC REPLACEMENT

What remains to be understood is how our color-kinematic replacement rule acts on the MJO-color basis factors \( C(\bar{1}, \bar{2}, \sigma) \). Here we find the key relation

\[ C(\bar{1}, \bar{2}, \sigma, p, \sigma') | R_{ap} = \frac{K}{2g} (e_p \cdot k_{2\sigma}) C(\bar{1}, \bar{2}, \sigma, \sigma') \]

where \( k_{2\sigma} := k_2 + k_{\sigma_1} + \ldots k_{\sigma_b} \) with \( b \) being the length of \( \sigma \). To prove this relation we closely follow a proof of a color factor symmetry found in [29]. In fact, this color factor symmetry may be understood as a direct corollary of our relation (11) under a gauge transformation \( e^\mu_p \to p^\mu \). We first prove (17) for vanishing \( \sigma \). Here with (8) and using the bracket notation we have

\[ C(\bar{1}, \bar{2}, p, \sigma') = \{ 2 | T^p \Omega_{[1]} \} \ldots = (-)^{\Omega+1} \{ 1 | \Omega T^p | 2 \} \ldots \]

where \( \Omega \) is determined by the Dyck word of \( \sigma \). One also defines \( T^p_{ji} := -T^p_{ij} \) in analogy to \( \tilde{f}^{abc} = -\tilde{f}^{cba} \). With \( T_{ap} \) we indeed find (17) for vanishing \( \sigma \). The nontrivial \( \sigma \) case is proven by induction. Let \( c = \sigma_b \) denote a gluon leg and write

\[ C(\bar{1}, \bar{2}, \sigma_1, \ldots, \sigma_b, p, \sigma_{b+1} \ldots, \sigma_{n-1}) =: C_{\ldots, [cp]} \ldots \]

We now assume that (17) is true for \( C_{\ldots, [pc]} \ldots \) and write

\[ C_{\ldots, [cp]} = \ldots \Xi_{\bar{i}}' \Xi_{\bar{i}} \ldots \]

as the two gluons are next to each other they appear at the same level of nestedness. Consider now the commutator of \( C_{\ldots, [cp]} \ldots \) and \( C_{\ldots, [pc]} \ldots \)

VI. SCALAR MATTER

Our central result Eq. (11) is in fact universal. It also applies to a theory of gravitationally minimally interacting massive, color charged scalars, Einstein-scalar-QCD. Clearly, the color structure of a scalar-QCD amplitude will be captured by the MJO basis as well. The relevant single graviton vertices are collected in Fig. 2. One again shows that the emission of a single graviton from a multi-scalar-gluon or even multi-scalar-gluon-quark process reduces to the BCJ-relation there is an associated single graviton amplitude. Relating single graviton EQCD amplitudes to QCD ones.

VII. DISCUSSION

In a sense the key statement of this paper is that for every BCJ-relation there is an associated single graviton amplitude: The BCJ-relation is nothing but the gauge invariance of this graviton. What about multiple gravitons? In [15] the figures and equations are not included in this text, but the authors conclude that their findings provide a new perspective on the color structure of graviton amplitudes and suggest further research is needed to fully understand the implications of their work for theories of strong gravity.
single graviton EYM relation was used as a seed for an all graviton multiplicity reduction of the single trace EYM amplitudes to pure YM ones. The only ingredients were gauge invariance and BCJ relations along with a structural assumption on the form of the higher graviton amplitudes. If one accepts this assumption also for our general matter case, the multigraviton, single trace formulas of [15] directly generalize. The situation for multicolor traces is less clear to us. Finally, we believe that (22) points toward a kinematical algebra structure consisting of a “mixed” color-kinematic representation which should be understood in more detail. All our results are dimension independent. We also checked our single graviton relation against known amplitudes involving massive quarks [30] and massive scalars [21] in the literature. Moreover, it is possible to extend our techniques to loop level amplitudes with one external on-shell graviton and no internal gravitons (leading order in \( \kappa \)). It is still possible to use the effective vertex notation except for the case where one inserts a graviton directly into a gluon loop. There it is not possible to use Ward identities and one additional term appears. Still, the new term will be of the same analytic form as the insertion term will be of the same analytic form as the insertion.

\[ L = L_{\text{QCD}} + L_{\text{YM}} + L_{\text{EH}} + L_{\text{GF}} + L_{\text{Ghost}}, \]

where \( R_{\mu\nu} \) is the usual Ricci tensor, \( \kappa \) is the gravitational coupling constant and \( D_{ij} = \partial_\mu \delta_{ij} - igA_\mu^a(T^a)_{ij} \) is the covariant derivative with \( g \) being the YM coupling. Furthermore, we take the textbook normalization of the SU(N) generators

\[ \text{Tr}(T^a T^b) = \frac{1}{2} \delta^{ab}. \]  

We consider the above theory in an expansion around the Minkowski vacuum

\[ g_{\mu\nu} = \eta_{\mu\nu} + \kappa h_{\mu\nu}, \]

and identify \( h_{\mu\nu} \) as the graviton. We choose the Feynman resp. de Donder gauge fixings

\[ L_{\text{GF}} = -\frac{1}{2} (\partial_\mu A_\nu^a)^2 + \left( \partial^\mu h_{\mu\nu} - \frac{1}{2} \partial_\mu h^\mu_{\nu\nu} \right)^2. \]  

The form of the ghost Lagrangian is not needed since we exclusively work at tree level. The interested reader is referred to [28].

The graviton is understood to carry momentum \( P \), polarization \( e^{\mu\nu} = e_\mu^P e_\nu^P \) and Lorentz indices \( \alpha \beta \). All momenta are ingoing. Gluons are denoted as wiggly lines, gravitons as double wiggly lines, fermions as solid arrows and scalars as dashed arrows.

\[ a \quad b = \frac{-i \eta_{\mu_2\mu_3} \delta^{ab}}{P^2} \]

\[ \alpha \beta \gamma \delta = \frac{i \bar{P}_{\alpha\beta\gamma\delta}}{P^2} \]

\[ i \quad j = \frac{i \delta^{ij}}{P^2 - m_\psi} \]

\[ i \quad j = \frac{i \delta^{ij}}{P^2 - m_\phi^2} \]

where we defined

\[ \bar{P}_{\alpha\beta\gamma\delta} = \eta_{\alpha\beta} \eta_{\gamma\delta} + \frac{1}{d-2} \eta_{\alpha\gamma} \eta_{\beta\delta} \]

\[ \eta_{\alpha\gamma} \eta_{\beta\delta} = \frac{1}{2} (\eta_{\alpha\gamma} \eta_{\beta\delta} + \eta_{\alpha\delta} \eta_{\beta\gamma}) \]  

ACKNOWLEDGMENTS

APPENDIX: DETAILS OF THE COMPUTATION

1. Feynman rules for Einstein-Yang-Mills-Scalar theory coupled to quarks

The theory under consideration is defined by the Lagrangian

\[ L = L_{\text{QCD}} + L_{\text{YM}} + L_{\text{EH}} + L_{\text{GF}} + L_{\text{Ghost}}, \]

with the usual definitions

\[ L_{\text{YM}} = -\frac{1}{4} g^{\rho\sigma} g^{\alpha\beta} F_{\mu\nu} F_{\rho\sigma} \]

\[ L_{\text{QCD}} = \sqrt{-g} \bar{\psi} (i \gamma^\mu D_\mu - m_\psi) \psi \]

\[ L_{\text{EYM}} = \sqrt{-\hat{g}} (g^{\mu\nu} (D_\nu \phi)^+ (D_\mu \phi) - m_\phi \phi^+ \phi) \]

\[ L_{\text{EH}} = \frac{2}{\kappa^2} \sqrt{-g} g^{\mu\nu} R_{\mu\nu}, \]  

\[ \text{Tr}(T^a T^b) = \frac{1}{2} \delta^{ab}. \]  

We consider the above theory in an expansion around the Minkowski vacuum

\[ g_{\mu\nu} = \eta_{\mu\nu} + \kappa h_{\mu\nu}, \]

and identify \( h_{\mu\nu} \) as the graviton. We choose the Feynman resp. de Donder gauge fixings

\[ L_{\text{GF}} = -\frac{1}{2} (\partial_\mu A_\nu^a)^2 + \left( \partial^\mu h_{\mu\nu} - \frac{1}{2} \partial_\mu h^\mu_{\nu\nu} \right)^2. \]  

The form of the ghost Lagrangian is not needed since we exclusively work at tree level. The interested reader is referred to [28].

The graviton is understood to carry momentum \( P \), polarization \( e^{\mu\nu} = e_\mu^P e_\nu^P \) and Lorentz indices \( \alpha \beta \). All momenta are ingoing. Gluons are denoted as wiggly lines, gravitons as double wiggly lines, fermions as solid arrows and scalars as dashed arrows.

\[ a \quad b = \frac{-i \eta_{\mu_2\mu_3} \delta^{ab}}{P^2} \]

\[ \alpha \beta \gamma \delta = \frac{i \bar{P}_{\alpha\beta\gamma\delta}}{P^2} \]

\[ i \quad j = \frac{i \delta^{ij}}{P^2 - m_\psi} \]

\[ i \quad j = \frac{i \delta^{ij}}{P^2 - m_\phi^2} \]

where we defined

\[ \bar{P}_{\alpha\beta\gamma\delta} = \eta_{\alpha\beta} \eta_{\gamma\delta} + \frac{1}{d-2} \eta_{\alpha\gamma} \eta_{\beta\delta} \]

\[ \eta_{\alpha\gamma} \eta_{\beta\delta} = \frac{1}{2} (\eta_{\alpha\gamma} \eta_{\beta\delta} + \eta_{\alpha\delta} \eta_{\beta\gamma}) \]  

026011-5
The interaction vertices with at most one graviton read [28] (define $P_{\alpha\beta\gamma\delta} = \tilde{P}_{\alpha\beta\gamma\delta|d=4}$)

$$a = g f^{abc} [\eta^{\mu_1\mu_2}(p_a - p_b)^{\mu_3} + \eta^{\mu_1\mu_2}(p_b - p_c)^{\mu_3} + \eta^{\mu_1\mu_2}(p_c - p_a)^{\mu_3}]$$

$$= -ig^2 \left[ f^{abc} f^{cde} (\eta^{\mu_1\mu_2\eta^{\mu_3\mu_4} - \eta^{\mu_1\mu_4\eta^{\mu_3\mu_2}}) + f^{ace} f^{bde} (\eta^{\mu_1\mu_2\eta^{\mu_3\mu_4} - \eta^{\mu_1\mu_4\eta^{\mu_3\mu_2}}) + f^{ade} f^{bce} (\eta^{\mu_1\mu_2\eta^{\mu_3\mu_4} - \eta^{\mu_1\mu_4\eta^{\mu_3\mu_2}}) \right]$$

$$a = ig^2 \left[ f^{abc} f^{cde} (p_a^{\alpha\beta} p_b + p_b^{\alpha\beta} p_a - \eta^{\mu_1\mu_2} p_a^{\mu_3} p_b^{\mu_3} + \frac{1}{2} \eta^{\alpha\beta} p_a^{\mu_3} p_b )\right]$$

$$= \kappa g f^{abc} \left[ p_a^{\alpha\beta} (p_b - p_a)^{\mu_3} + p_a^{\alpha\beta} (p_a - p_c)^{\mu_3} + p_a^{\alpha\beta} (p_c - p_b)^{\mu_3} + \eta^{\mu_1\mu_2} (p_b - p_a)^{\beta} + \eta^{\mu_1\mu_3} (p_a - p_c)^{\alpha} + \eta^{\mu_2\mu_3} (p_c - p_b)^{\beta} \right]$$
\[
\frac{i\kappa}{2} \left[ \eta^{\alpha\beta} \left( \not{p}_i - m_\psi + \frac{1}{2}\not{\psi} \right) - \gamma^{(\alpha}(p_i + \frac{1}{2}\not{\psi})^{\beta)} \right] \delta^{ji} \tag{A19}
\]

\[
\frac{i\kappa}{2} \eta^{\alpha\beta} \left( -p_i \cdot p_j - m_i^2 \right) + p_i^{(\alpha} p_j^{\beta)} \delta^{ji} \tag{A20}
\]

\[
a = ig \gamma^{\mu_\alpha} (T^\alpha)_{j\bar{i}} \tag{A21}
\]

\[
a = ig (p_i - p_j)^{\mu_\alpha} (T^\alpha)_{j\bar{i}} \tag{A22}
\]

\[
\frac{i\kappa g}{2} \left[ \eta^{\alpha\beta} (p_i - p_j)^{\mu_\alpha} - \eta^{\mu_\alpha (\alpha} (p_i - p_j)^{\beta)} \right] (T^\alpha)_{j\bar{i}} \tag{A23}
\]

\[
\frac{ig^2}{2} \gamma^{\mu_\alpha \mu_\beta} \{ T^\alpha, T^\beta \} \tag{A24}
\]
2. On-shell and effective Feynman rules

We construct on-shell Feynman rules by contracting one external graviton or gluon with its polarization tensor and using the conditions $\varepsilon_P \cdot P = \varepsilon_P^2 = 0$. Graphically we denote the on-shell leg with a triangle. We start with the two gluon one graviton vertex:

$$i \kappa g \delta^{ab} \left[ \frac{1}{2} (p_a^2 + p_b^2) \varepsilon_{P}^{\mu_a} \varepsilon_{P}^{\mu_b} + (\varepsilon_P \cdot p_a) (M^{\mu_a \mu_b} + W^{\mu_a \mu_b}) \right],$$

where we defined

$$M^{\mu \nu} = (\varepsilon_P \cdot p_a) \eta^{\mu \nu a} + \varepsilon_{P}^{\mu} p_{P}^{\nu a} - \varepsilon_{P}^{\nu} p_{P}^{\mu a},$$

$$W^{\mu \nu} = \varepsilon_{P}^{\mu} p_{b}^{\nu a} - \varepsilon_{P}^{\nu} p_{a}^{\mu a}. \tag{A28}$$

Moreover we used

$$p_a \cdot p_b = \frac{1}{2} ((p_a + p_b)^2 - p_a^2 - p_b^2), \tag{A29}$$

where the first term in the bracket is $p^2 = 0$. We write this as

$$= + + +$$

And identify
Note that in any tree level computation of a scattering amplitude the term $W^{\mu,\nu}(p_a, p_b)$ will vanish due to on-shell Ward identities. It is now straightforward to obtain

\[ i \kappa g \frac{p_a^2 \epsilon_{\alpha} \cdot \epsilon_{\beta}}{p \cdot p} \delta^{ab} \]

\[ i \kappa g \frac{p_a^2 \epsilon_{\alpha} \cdot \epsilon_{\beta}}{p \cdot p} \delta^{ab} \]

\[ i \kappa g (\epsilon \cdot p \cdot p_a) M^{\alpha,\beta} \delta^{ab} \]

\[ i \kappa g (\epsilon \cdot p \cdot p_a) W^{\mu,\nu} \delta^{ab} \]

Note that in any tree level computation of a scattering amplitude the term $W^{\mu,\nu}(p_a, p_b)$ will vanish due to on-shell Ward identities. It is now straightforward to obtain
with the identification of the effective Feynman rules

\[ \frac{\kappa g}{2} f^{abc} \left[ \eta^{\mu_\alpha \mu_\beta} \varepsilon_\alpha^\mu (\varepsilon_\beta \cdot (p_b - p_a)) + \eta^{\mu_\alpha \mu_\beta} \varepsilon_\beta^\mu (\varepsilon_\alpha \cdot (p_a - p_c)) + \eta^{\mu_\alpha \mu_\beta} \varepsilon_\alpha^\mu (\varepsilon_\beta \cdot (p_c - p_b)) \right] \]  

\[ \frac{i \kappa g}{2} \varepsilon_\alpha^\mu (\varepsilon_\beta \cdot (p_i - p_j)) (T^a)_{j\bar{i}}. \]  

The last two on-shell Feynman rules are

\[ \frac{i \kappa}{2} \varepsilon_\beta (\varepsilon_\alpha \cdot p_i) \delta_{j\bar{i}} \]
which we can compare to the on-shell Feynman rules of pure YM—one of the gluon legs is taken to be external and contracted with its polarization tensor. Consider

\[ p = ig f^a_p (T^p)_{ji} \]  

\[ p = 2ig (\varepsilon_p \cdot p_i) (T^p)_{ji} \]

where we used momentum conservation in the two scalar one gluon Feynman rule \( p_j = -p_i - p_a \). Upon a closer look we notice that we can reach the effective vertices with an external graviton via the prescription

\[ (T^p)_{ji} \rightarrow \frac{\kappa}{2g} (\varepsilon_p p_j) \delta^{ji}, \quad (T^p)_{ji} \rightarrow -\frac{\kappa}{2g} (\varepsilon_p p_i) \delta^{ji}. \]

Similarly we obtain

\[ f_{apb} = i(T^p)_{ab} \rightarrow -i \frac{\kappa}{2g} (\varepsilon_p p_a) \delta^{pb}, \quad i(T^p)_{ab} \rightarrow i \frac{\kappa}{2g} (\varepsilon_p p_b) \delta^{ab}. \]

We observe that the prescription of the fundamental color factors differs to the adjoint factors by a minus sign. Nevertheless, we can define adjoint color factors \( \tilde{f}^{abc} = i f^{abc} \) which will have the exact same behaviour in the color to kinematics prescription. Higher multiplicity vertices can also be generated by this prescription. We start with the case
\[ t^i_j = i g^2 \varepsilon^\mu_a \left( (T^a)_{jk} (T^p)_{ki} + (T^p)_{jk} (T^a)_{ki} \right) \]  

(A49)

\[
\begin{aligned}
(T^p)_{ki} &\rightarrow -\frac{\kappa}{2g} (e_p \cdot p_i) \delta^k_j,
(T^p)_{jk} &\rightarrow \frac{\kappa}{2g} (e_p \cdot p_j) \delta^k_j,
\end{aligned}
\]

(A50)

we can see that we land exactly on (A41). The four gluon vertex is more involved. We start by writing

\[ f_{cbe} f^{cae} - f_{ca} f^{cbe} = -i (f_{cbe} f^{ca} + f^{cae} f^{bep}) = -i (f_{cbe} f^{cae} + f^{cae} f^{bpe}) \]

(A51)

Let us focus on the first color structure

\[ f_{cbe} f^{ca} + f^{cae} f^{bpe} = -i (f_{cbe} f^{cae} + f^{cae} f^{cbe}) \]

(A52)

Hence

\[ -ig^2 \varepsilon^{\mu_a} \eta^{\mu_b} (f_{cbe} f^{cae} - f^{cae} f^{cbe}) \]

(A53)

which is exactly the first term in (A40). The other terms are reached in exactly the same fashion. This section concludes two statements

1. From the notion of effective on-shell Feynman rules we can deduce that the number of possible graviton insertions into a tree level diagram is the same as the amount of possible gluon insertions into the same diagram.
2. The effective on-shell Feynman rules with one external graviton, and therefore diagrams including such vertices, can be generated by the proposed double copy from pure gluon Feynman rules.

3. Proof of key relation

Equation (17) has already been proven in the case of \( \sigma_b = c \) being a gluon. It is straightforward to prove the other cases. Case 1 \( \sigma_b = c \) is an antiquark: The color factor will have some expression that depends on the Dyck word. Nevertheless we may zoom in on the position of insertion and read

\[ C_{c|\varepsilon|p|\ldots} = \cdots \{ c \} T^c \otimes \Xi_{j-1}^c \Xi_j^p \cdots = \cdots \{ c \} |T^c \otimes (\Xi_{j-1}^c \Xi_j^p) \cdots |, \]

(A54)

where we used the definition (9). Similarly we get

\[ C_{c|\varepsilon|p|\ldots} = \cdots \Xi_{j-1}^p \{ c \} T^c \otimes \Xi_{j-1}^c \cdots = \cdots \{ c \} |T^c \otimes (\Xi_{j-1}^p \Xi_{j-1}^c) \cdots |. \]

(A55)

Now computing the commutator will give

026011-12
\[ C_{\cdots |cp|\cdots} - C_{\cdots |pc|\cdots} = \cdots \{ c| \left( T^c T^p \right) \otimes \Xi_{\ell-1}^c \cdots + \cdots \{ c|T^c \otimes \left( \left[ \Xi_{\ell-1}^c, \Xi_{\ell-1}^p \right] \right) \cdots \]
\[ = \cdots \{ c| \left( T^p T^c \right) \otimes \Xi_{\ell-1}^c \cdots + \cdots \{ c| \left( [T^c, T^p] \right) \otimes \Xi_{\ell-1}^c \cdots + \cdots \{ c|T^c \otimes \left( \left[ \Xi_{\ell-1}^c, \Xi_{\ell-1}^p \right] \right) \cdots \]
\[ = \cdots \{ c| \left( T^p T^c \right) \otimes \Xi_{\ell-1}^c \cdots + \cdots \{ c| \left( T^c T^p \right) \otimes \Xi_{\ell-1}^c \cdots + \cdots \{ c| \left( [T^c, T^p] \right) \otimes \Xi_{\ell-1}^c \cdots + \cdots \}
\]

immediately implying
\[ (C_{\cdots |cp|\cdots} - C_{\cdots |pc|\cdots})|_{\mathcal{R}_p} = (e_p \cdot k_c) C_{\cdots |c|\cdots}. \] (A57)

Case 2 \( \sigma_b = c \) is a quark: We zoom in and see
\[ C_{\cdots |cp|\cdots} = \cdots \{ c| \Xi_{\ell+1}^c \cdots, \]
\[ C_{\cdots |pc|\cdots} = \cdots \{ c| \Xi_{\ell+1}^p \cdots = \cdots \{ T^p c \cdots + \cdots \{ c| \Xi_{\ell+1}^p \cdots. \] (A58)

Hence the commutator is just
\[ C_{\cdots |cp|\cdots} - C_{\cdots |pc|\cdots} = -\cdots \{ T^p c \cdots, \] (A59)

and we immediately obtain
\[ (C_{\cdots |cp|\cdots} - C_{\cdots |pc|\cdots})|_{\mathcal{R}_p} = (e_p \cdot k_c) C_{\cdots |c|\cdots}. \] (A60)

This concludes the proof of (17).
