Abstract

Starting from the time evolution of the C-odd $\bar{K}^0 K^0$ system, we analyze the asymmetries measurable at DAΦNE and their implications on CP violation and on the possible tests of T and CPT symmetries. In particular the ratio $\frac{a}{f}$ can be measured with high precision (up to about $10^{-4}$ for the real part). The CP-, T- and CPT-violating parameters can be explored in $K_S$ semileptonic decays with an accuracy of the order of $10^{-3}$. The possibility to detect $K_S \to 3\pi$ and $K_L \to \pi\pi\gamma$ decays is also discussed.

1 Introduction

The $K^0 \overline{K}^0$ state produced in the decay of the $\phi$ resonance is odd under charge conjugation and is therefore an antisymmetric $K_L \overline{K}_S$ state. This characteristic makes a $\phi$ factory very suitable to study CP violation and to test CPT symmetry in $K$ meson decays [1, 2].

For a long time it has been stressed that the presence in the same detector of $K_L$ and $K_S$ beams, produced without regeneration and thus with the relative fluxes perfectly known, will allow a very clean determination of the ratio $\frac{\mathcal{L}}{\mathcal{L}}$ [3]. A non-zero value for $\frac{\mathcal{L}}{\mathcal{L}}$ is an unambiguous signal of the existence of direct CP violation, which is naturally expected in the Standard Model. The present experimental situation is:

$$\Re \left( \frac{\mathcal{L}}{\mathcal{L}} \right) = (2.3 \pm 0.7) \times 10^{-3} \quad \Im \left( \frac{\mathcal{L}}{\mathcal{L}} \right) = (-1.2 \pm 1.7) \times 10^{-3} \quad \text{NA31}[4]$$

$$\Re \left( \frac{\mathcal{L}}{\mathcal{L}} \right) = (0.74 \pm 0.60) \times 10^{-3} \quad \Im \left( \frac{\mathcal{L}}{\mathcal{L}} \right) = (+4.7 \pm 3.5) \times 10^{-3}, \quad \text{E731}[5]$$

still consistent with $\mathcal{L} = 0$. The theoretical calculation of $\frac{\mathcal{L}}{\mathcal{L}}$ in the Standard Model is strongly affected by QCD corrections and, for large values of the top mass, large cancellations are expected [6]. The present estimate is $\Re \left( \frac{\mathcal{L}}{\mathcal{L}} \right) = (2.8 \pm 2.4) \times 10^{-4}$, [7] thus a fundamental goal of DAΦNE is certainly to reach the sensitivity of $10^{-4}$ in the measurement of this ratio. Independent information about direct CP violation could be obtained also by charge asymmetries in $K^\pm \to 3\pi$ [8] and $K^\pm \to 2\pi \gamma$ [9] decays.

Beyond the study of direct CP violation, the presence of a pure $K_S$ beam will allow the observation at DAΦNE of some suppressed $K_S$ decays, such as the semileptonic and the three-pion ones. The theoretical predictions for semileptonic decays are not strongly affected by QCD corrections and, as we will discuss later, the measurement of the semileptonic rates and charge asymmetries in $K_{S,L}$ decays can give many interesting tests of CPT and of the $\Delta S = \Delta Q$ rule. Moreover, due to the coherence of the initial state, $T$ and CPT symmetries can be directly tested in events with two leptons in the final state [10, 11].

Some time ago it was pointed out that the radiative decay $\phi \to \gamma f_0 \to \gamma (K^0 \overline{K}^0)_{c=+}$ could have a non-negligible branching ratio [12] and therefore a dangerous background, namely a $K^0 \overline{K}^0$ component even under charge conjugation, could be present. New determinations of the $\phi \to \gamma (K^0 \overline{K}^0)_{c=+}$ branching ratio [13] turn out to be much smaller, then, as we will show, the inclusion of the C-even background does not sensibly affect the measurements of $\frac{\mathcal{L}}{\mathcal{L}}$ and $K_S$ suppressed decays.

Recently it has been suggested that quantum mechanics violations may be generated by non-local theories at the Planck scale [14]. As a consequence CP- and CPT-violating effects could be induced [15]. As we will discuss, the coherence of the $\phi$-factory initial state will help in disentangling these effects, and quite stringent bounds could be obtained for the quantum mechanics violating parameters [16]. It is worth while to note that the quantum mechanics violation induces a loss of the initial state coherence which can somehow simulate the effect of a C-even background.

The plan of the paper is the following: in section 2 we recall the time evolution of the initial state. In section 3 we report its implications on the determination of real and
imaginary parts of $\zeta$. In section 4 the semileptonic decays, with possible direct tests of $T$ and CPT symmetry, are discussed. Sections 5 and 6 are devoted, respectively, to $K_S \to 3\pi$ and $K_L \to \pi\pi\gamma$ decays. In section 7 we study the effect of the C-even background. Finally, in section 8 we discuss the implications of possible quantum mechanics violations.

2 Time evolution

The antisymmetric $\bar{K}^0K^0$ state produced in the $\phi$ decay can be written as

$$\phi \to \frac{1}{\sqrt{2}} \left[ K_0^0 K_0^{(-)} - K_0^{(-)} K_0^{0} \right] = \frac{h}{\sqrt{2}} \left[ K_S^{(s)} K_L^{(-)} - K_L^{(s)} K_S^{(-)} \right],$$

where $q$ and $-q$ indicate the spatial momenta of the two-kaons and the normalization factor $h$ is

$$h = \frac{1 + |e|^2}{1 - |e|^2} \approx 1.$$ 

The decay amplitude of the two-kaon system into the final state $|\phi^{(s)}(t_1), b^{(-)}(t_2)\rangle$ is given by:

$$A \left( a^{(s)}(t_1), b^{(-)}(t_2) \right) = \frac{h}{\sqrt{2}} \left[ A(K_S \to a)e^{-i\lambda_S t_1} A(K_L \to b)e^{-i\lambda_L t_2} - A(K_L \to a)e^{-i\lambda_L t_1} A(K_S \to b)e^{-i\lambda_S t_2} \right],$$

where $\lambda_{S(L)} = m_{S(L)} - i\Gamma_{S(L)}/2$. As usual we define also:

$$\Gamma = \frac{\Gamma_S + \Gamma_L}{2}, \quad \Delta\Gamma = \Gamma_S - \Gamma_L \quad \text{and} \quad \Delta m = m_L - m_S.$$ 

If $|a\rangle \neq |b\rangle$ the two states $|a^{(s)}(t_1), b^{(-)}(t_2)\rangle$ and $|a^{(-)}(t_1), b^{(s)}(t_2)\rangle$ are physically different for any value of $t_1$ and $t_2$, therefore the double differential rate is:

$$\Gamma(a(t_1), b(t_2)) = |h|^2 \int \left\{ |A_S^a|^2 |A_L^b|^2 e^{-\Gamma_{S(t_1)} + \Gamma_{L(t_2)}} + |A_L^a|^2 |A_S^b|^2 e^{-\Gamma_{L(t_1)} + \Gamma_{S(t_2)}} 
-2\Re \left[ A_S^a A_L^b A_S^b A_L^a e^{-\Gamma_{S(t_1)} + \Gamma_{S(t_2)}} \right] \right\} d\phi_a d\phi_b,$$

where $\phi_a$ and $\phi_b$ are the phase spaces of the final states. Integrating eq. (5) on $t_1$ and $t_2$, one obtains the probability for the decay into the $|a, b\rangle$ state with both the decay vertices inside the detector:

$$P(a, b) = \frac{|h|^2}{\Gamma_S \Gamma_L} \left[ \left( \Gamma_S^a \Gamma_L^b + \Gamma_L^a \Gamma_S^b \right) S_L - 2 \frac{\Gamma_S \Gamma_L}{\Gamma^2 + \Delta m^2} \int \Re \left( A_S^a A_L^a A_L^b A_S^b e^{-\Gamma_{S(t_1)} + \Gamma_{L(t_2)}} \right) d\phi_a d\phi_b \right],$$

where $S_L = (1 - e^{-D/d_L})$ is the $K_L$ acceptance of the detector: the KLOE project quotes for the fiducial length $D \approx 120 \text{ cm}$ [3] ($d_L = 340 \text{ cm}$ is the $K_L$ mean decay path), thus $S_L \approx 0.3$. 

2
For $|a| = |b|$ the interchange of $q \leftrightarrow -q$ is equivalent to $t_1 \leftrightarrow t_2$, thus:

$$P(a, a) = |h|^2 \Gamma_S^e \Gamma_L^e \left[ S_L - \frac{\Gamma_S \Gamma_L}{\Gamma^2 + \Delta m^2} \right].$$ (7)

As will be discussed in the following, the choice of appropriate time integration intervals supplies a powerful tagging of $K_L$ or $K_S$ decays.

Finally we define also the so-called “time difference distribution”:

$$I(a, b; t) = \int dt_1 dt_2 |A(a(t_1), b(t_2))|^2 \delta(t_1 - t_2 - t)$$

$$= \frac{|h|^2 e^{-\Gamma |t|}}{2\Gamma} \left\{ |A_S^e|^2 |A_L^e|^2 e^{-\frac{\Delta \rho}{2}|t|} + |A_S^b|^2 |A_L^b|^2 e^{+\frac{\Delta \rho}{2}|t|} - 2\Re \left[ A_S^e A_S^b^* A_L^e A_L^b^* e^{+i\Delta m t} \right] \right\}. \quad (8)$$

3 Real and imaginary parts of $\frac{\epsilon'}{\epsilon}$

As extensively discussed, for example in Refs. [3, 17, 18], the study of the time difference distribution, for $\pi^+\pi^-$, $\pi^0\pi^0$ final states, leads to the determination of both $\Re \left( \frac{\epsilon'}{\epsilon} \right)$ and $\Im \left( \frac{\epsilon'}{\epsilon} \right)$.

Introducing as usual the amplitudes

$$\eta^{+} = \frac{A(K_L \rightarrow \pi^+\pi^-)}{A(K_S \rightarrow \pi^+\pi^-)} = \epsilon + \epsilon' \quad \text{and} \quad \eta^{00} = \frac{A(K_L \rightarrow \pi^0\pi^0)}{A(K_S \rightarrow \pi^0\pi^0)} = \epsilon - 2\epsilon', \quad (9)$$

eq. (8), integrated over the pion phase space, gives:

$$F(t) = \int d\phi_+ d\phi_0 I(\pi^+\pi^-, \pi^0\pi^0; t)$$

$$= \frac{\Gamma_S^e \Gamma_L^e}{2\Gamma} e^{-\Gamma |t|} \left[ |\eta^{+}|^2 e^{-\frac{\Delta \rho}{2}|t|} + |\eta^{00}|^2 e^{\frac{\Delta \rho}{2}|t|} - 2\Re \left( \eta^{+} (\eta^{00})^* e^{-i\Delta m t} \right) \right]. \quad (10)$$

If $\epsilon' \neq 0$ there is an asymmetry between the events with positive and negative values of $t$:

$$A(t) = \frac{F(|t|) - F(-|t|)}{F(|t|) + F(-|t|)} = A_R(t) \times \Re \left( \frac{\epsilon'}{\epsilon} \right) - A_I(t) \times \Im \left( \frac{\epsilon'}{\epsilon} \right), \quad (11)$$

neglecting in eq. (11) terms proportional to $\left( \frac{\epsilon'}{\epsilon} \right)^2$, the $A_R(t)$ and $A_I(t)$ coefficients, shown in Fig.1, are given by:

$$A_R(t) = \frac{3}{4} \frac{e^{-|t|\Gamma_L} - e^{-|t|\Gamma_S}}{e^{-|t|\Gamma_L} + e^{-|t|\Gamma_S} - 2 \cos (\Delta m |t|) e^{-|t|\Gamma}}.$$ (12)

$$A_I(t) = \frac{3}{4} \frac{2 \sin (\Delta m |t|) e^{-|t|\Gamma}}{e^{-|t|\Gamma_L} + e^{-|t|\Gamma_S} - 2 \cos (\Delta m |t|) e^{-|t|\Gamma}}.$$ (12)
Figure 1: Coefficients of $\Re \left( \frac{c'}{c} \right)$ (full line) and $\Im \left( \frac{c'}{c} \right)$ (dashed line) defined in eq.(11).

It can be seen that $A_R(t)$ becomes nearly independent of $t$, and equal to 3, for $t \gg \tau_S$; on the other hand $A_I(t)$ is strongly dependent on $t$ and vanishes for $t \gg \tau_S$.

Therefore a measurement of the asymptotic value of $A(t)$ or of the value of the integrated asymmetry

$$A = \frac{F(t > 0) - F(t < 0)}{F(t > 0) + F(t < 0)} \approx 3 \Re \left( \frac{c'}{c} \right)$$

allows a clean determination of $\Re \left( \frac{c'}{c} \right)$. The statistical error on $A$ is given by:

$$\sigma_A = \sqrt{\frac{(1 + A) \times (1 - A)}{N}},$$

where $N$ is the number of $\phi \rightarrow \pi^+\pi^-, \pi^0\pi^0$ events. At the reference DAΦNE luminosity the statistical error on $\Re \left( \frac{c'}{c} \right)$ is then:

$$\frac{\sigma_{\Re} \left( \frac{c'}{c} \right)}{3} \approx \frac{1}{3\sqrt{N}} \approx 1.7 \times 10^{-4}.$$  \hspace{1cm} (15)

The integrated asymmetry $A$ allows a precise determination of $\Re \left( \frac{c'}{c} \right)$ but gives no information on the imaginary part of $\frac{c'}{c}$. To overcome this problem a further method can be exploited to measure both $\Re \left( \frac{c'}{c} \right)$ and $\Im \left( \frac{c'}{c} \right)$ from the $K_LK_S \rightarrow \pi^0\pi^0, \pi^+\pi^-$ decay.
Figure 2: Comparison between the theoretical $F(d)$ distribution for $\Re \left( \zeta' \right) = 2.8 \times 10^{-4}$ and that obtained with an experimental vertex resolution $\sigma = 5 \text{mm}$.

time difference: the experimental distribution $F(d)$ \footnote{The decay times are measured through the decay paths, and the time difference $t$ is given by $t = (d_c - d_n) \tau_S / d_S = d \tau_S / d_S$, where $d_c$ ($d_n$) is the decay path into charged (neutral) pions and $d_S \simeq 0.6 \text{cm}$ is the mean decay path of the $K_S$.} can be fitted by the theoretical distribution of eq. (10), and $\Re \left( \zeta \right)$ and $\Im \left( \zeta \right)$ can be used as free parameters of the fit.

It must be stressed that this procedure is very sensitive to the experimental resolution on the measurement of $d$. The information contained in the shape of the $F(d)$ distribution can be easily washed out, in particular in the region of interest for the determination of $\Im \left( \zeta \right)$, where $d \simeq d_S$. In fact only in this range of $d$ values can $A_I (d)$ be different from zero and the strongly varying behaviour of $A_I (d)$ smeared out by a bad vertex reconstruction. This effect is shown in Fig. 2, where the theoretical distribution is compared with a simulated experimental distribution with a Gaussian error on the $d$ measurement equal to 5 mm.
The effects of the finite experimental resolution have been discussed, for example in [18], to which we refer. The results of the quoted analysis are that the determination of \( \Re\left(\phi'\right) \) is practically unaffected by the experimental resolution, while the statistical error on \( \Im\left(\phi'\right) \) increases by more than a factor 2. This analysis estimates that the accuracy achievable for a realistic detector is:

\[
\sigma_{\Re}\left(\phi'\right) = 1.8 \times 10^{-4} \quad ; \quad \sigma_{\Im}\left(\phi'\right) = 3.4 \times 10^{-3}.
\]

These numbers have to be compared with the present experimental situation shown in the introduction.

4 Semileptonic Decays

4.1 Theoretical introduction

We will discuss the semileptonic decays of neutral kaons in a very general framework, without assuming the \( \Delta S = \Delta Q \) rule and the CPT symmetry.

The \( \Delta S = \Delta Q \) rule is well supported by experimental data and is naturally accounted for by the Standard Model, where the \( \Delta S = -\Delta Q \) transitions are possible only with two effective weak vertices. Explicit calculations give a suppression factor of about \( 10^{-6}-10^{-7} \) [19]. Furthermore in any quark model, \( \Delta S = -\Delta Q \) transitions can be induced only by operators with dimension higher than 6 and therefore are suppressed [20].

Although it is very unlikely to have a theory with a large violation of the \( \Delta S = \Delta Q \) rule, this does not conflict with any general principle. On the contrary CPT symmetry must hold in any Lorentz-invariant local field theory. The problem of possible sources of CPT violation has recently received much attention. Attempts to include also gravitation in the unification of fundamental interactions lead to non-local theories, like superstrings, which suggest possible CPT violation above the Planck mass, which turns out to be the natural suppression scale [21].

We neglect for the moment quantum mechanics violating effects [14, 15], which will be discussed later, introducing CPT violation through an “ad hoc” parametrization of the decay amplitudes and the mass matrix elements.

Following the notations of Ref. [20] we define:

\[
\begin{align*}
A(K^0 \to l^+ \nu \pi^-) & = a + b \\
A(K^0 \to l^- \nu \pi^+) & = c + d \\
A(\bar{K}^0 \to l^- \nu \pi^+) & = a^* - b^* \\
A(\bar{K}^0 \to l^+ \nu \pi^-) & = c^* - d^*
\end{align*}
\]

CPT implies \( b = d = 0 \), CP implies \( \Im(a) = \Im(c) = \Re(b) = \Re(d) = 0 \), T requires real amplitudes and \( \Delta S = \Delta Q \) implies \( c = d = 0 \).
Writing the mass matrix for the $K^0 \bar{K}^0$ system in the form:

\[
\begin{pmatrix}
M_{11} - i\Gamma_{11}/2 & M_{12} - i\Gamma_{12}/2 \\
M_{21} - i\Gamma_{21}/2 & M_{22} - i\Gamma_{22}/2
\end{pmatrix},
\]

the eigenstates are given by:

\[
K_S = \frac{1}{\sqrt{2(1 + |\epsilon_s|^2)}} \left[ (1 + \epsilon_s) K^0 + (1 - \epsilon_s) \bar{K}^0 \right]
\]

\[
K_L = \frac{1}{\sqrt{2(1 + |\epsilon_L|^2)}} \left[ (1 + \epsilon_L) K^0 - (1 - \epsilon_L) \bar{K}^0 \right],
\]

where the $\epsilon$ parameters are:

\[
\epsilon_S = \frac{-i \Im (M_{12}) - \frac{1}{2} \Im (\Gamma_{12}) - \frac{1}{2} \left[ M_{11} - M_{22} - \frac{1}{2} (\Gamma_{11} - \Gamma_{22}) \right]}{m_L - m_S + i(\Gamma_S - \Gamma_L)/2} = \epsilon_M + \Delta
\]

\[
\epsilon_L = \frac{-i \Im (M_{12}) - \frac{1}{2} \Im (\Gamma_{12}) + \frac{1}{2} \left[ M_{11} - M_{22} - \frac{1}{2} (\Gamma_{11} - \Gamma_{22}) \right]}{m_L - m_S + i(\Gamma_S - \Gamma_L)/2} = \epsilon_M - \Delta.
\]

Then the masses and widths are:

\[
m_{S(L)} = \frac{M_{11} + M_{22}}{2} \pm \Re (M_{12}), \quad \Gamma_{S(L)} = \frac{\Gamma_{11} + \Gamma_{22}}{2} \pm \Re (\Gamma_{12}).
\]

CPT symmetry would require $M_{11} = M_{22}$ and $\Gamma_{11} = \Gamma_{22}$, recovering the relation $\epsilon_S = \epsilon_L = \epsilon_M$.

Using eqs. (17) and (19) the semileptonic partial rates are given by:

\[
\Gamma_{S}^{L/}\bar{L} = \frac{|a|^2}{2} \left[ 1 \pm 2\Re (\epsilon_S) \pm 2\Re \left( \frac{b}{a} \right) + 2\Re \left( \frac{c^*}{a} \right) \mp 2\Re \left( \frac{d^*}{a} \right) \right]
\]

\[
\Gamma_{L}^{L/}\bar{L} = \frac{|a|^2}{2} \left[ 1 \pm 2\Re (\epsilon_L) \pm 2\Re \left( \frac{b}{a} \right) - 2\Re \left( \frac{c^*}{a} \right) \pm 2\Re \left( \frac{d^*}{a} \right) \right];
\]

thus the charge asymmetries for $K_S$ and $K_L$ are:

\[
\delta_S = \frac{\Gamma_{S}^{+} - \Gamma_{S}^{-}}{\Gamma_{S}^{+} + \Gamma_{S}^{-}} = 2\Re (\epsilon_S) + 2\Re \left( \frac{b}{a} \right) - 2\Re \left( \frac{d^*}{a} \right)
\]

\[
\delta_L = \frac{\Gamma_{L}^{+} - \Gamma_{L}^{-}}{\Gamma_{L}^{+} + \Gamma_{L}^{-}} = 2\Re (\epsilon_L) + 2\Re \left( \frac{b}{a} \right) + 2\Re \left( \frac{d^*}{a} \right).
\]
A non-vanishing value of the difference $\delta_S - \delta_L$ would be an evidence of CPT violation, either in the mass matrix or in the $\Delta S = -\Delta Q$ amplitudes ($\Delta$ and $d^*/a$ cannot be disentangled by semileptonic decays alone). The sum $\delta_S + \delta_L$ has CPT-conserving ($\Re(\epsilon_M)$) and CPT-violating ($\Re(a/b)$) contributions that cannot be disentangled.

The ratio of $K_S$ and $K_L$ semileptonic widths

$$\eta = \frac{\Gamma'_S}{\Gamma_L} = 1 + 4\Re\left(\frac{e^*}{a}\right),$$

where $\Gamma'_{S(L)} = \Gamma^S_{S(L)} + \Gamma^L_{S(L)}$, allows us to determine the CPT-conserving part of the amplitudes with $\Delta S = -\Delta Q$.

All imaginary parts disappear from the rates and only the time evolution can potentially give some information on them.

### 4.2 Determination of semileptonic branching ratios at DAΦNE

The semileptonic branching ratios of the $K_S$ can be measured at DAΦNE by selecting the following final states $|l^\pm \pi^\mp \nu(t_1), x_L(t_2)|$, where $t_1 \leq 10\tau_S$, $t_2 \geq 10\tau_S$ and $|x_L|$ is one of the allowed final states in $K_L$ decays ($|\pi^\mp \pi^- \pi^0|$ or $|l^\pm \pi^\mp \nu|$). The probability of such events is obtained by integrating eq. (5) in the appropriate time intervals. Therefore the number of events for $N_0$ initial $K_S K_L$ pairs is given by:

$$N_S(l^\pm) = N_0 \left\{ Br(K_S \rightarrow l^\pm \pi^\mp \nu) Br(K_L \rightarrow x_L) S_1 + Br(K_L \rightarrow l^\pm \pi^\mp \nu) Br(K_S \rightarrow x_L) S_2 - \Re \left[ S_3 \int A(K_S \rightarrow l^\pm \pi^\mp \nu) A^*(K_L \rightarrow l^\pm \pi^\mp \nu) A(K_L \rightarrow x_L) A^*(K_S \rightarrow x_L) \frac{d\phi_{x_L} d\phi_{x_L}}{\Gamma_S \Gamma_L} \right] \right\};$$

where

$$S_1 = (1 - e^{-10}) \left( e^{-10 \frac{\Gamma_S}{\Gamma_L}} - e^{-10 \frac{\Gamma_L}{\Gamma_S}} \right) = 0.28 \approx S_L,$$

$$S_2 = \left( 1 - e^{-10 \frac{\Gamma_L}{\Gamma_S}} \right) e^{-10} = 7.8 \times 10^{-7},$$

$$S_3 = \frac{2\Gamma_S \Gamma_L}{|\Gamma|^2 + |\Delta m|^2} e^{-10 \frac{\Gamma_L + i\Delta m}{\Gamma_S}} = (0.3 - i4.8) \times 10^{-5}.$$

As can be seen, $S_1$ is by far the dominant contribution; the branching ratio products in eq. (25) are predicted to be of the same order, while the interference term should be

---

3If CPT is not conserved the only change in time evolution equations concerns the normalization factor, which becomes $h = \sqrt{(1 + |\epsilon_L|^2)(1 + |\epsilon_S|^2)/(1 - \epsilon_L \epsilon_S)} \approx 1$.

3The general constraints on the time intervals for $K_S$ tagging are: $t_1 \leq t_{1\text{max}}$ and $t_2 \geq t_{2\text{min}}$, with $\tau_S \ll t_{1\text{max}} \ll t_{2\text{min}} \ll \tau_L$. A good choice is given by $t_{1\text{max}} = t_{2\text{min}} = 10\tau_S$. 

---
The project luminosity of DAΦNE (\(L = 5 \times 10^{32} \text{ cm}^2 \text{s}^{-1}\)) gives about \(8.6 \times 10^9 K_L K_S/\text{year}\). Using eq. (22) and the present upper limit on the violation of the \(\Delta S = \Delta Q\) rule [22], we estimate \(Br(K_S \to \mu^\pm \pi^\mp \nu) = 4.66 \times 10^{-4}\) and \(Br(K_S \to e^\pm \pi^\mp \nu) = 6.68 \times 10^{-4}\), therefore \(2.1 \times 10^6\) events/year are expected.

With these numbers we can estimate the sensitivity of DAΦNE to CP, CPT and the \(\Delta S = \Delta Q\) rule violating parameters defined in eqs. (23) and (24). Since the \(\mu^\mp \pi^- \nu\) final state can hardly be distinguished from the \(\mu^- \pi^+ \bar{\nu}\) one, we conservatively assume that only electrons can be used to derive \(K_S\) charge asymmetry. In this case the number of event is \(1.2 \times 10^6/\text{year}\) and the statistical error on \(\delta_S\) turns out to be \(\sigma_{\delta_S} = 9.0 \times 10^{-4}\). Since the experimental value of \(K_L\) charge asymmetry is \(\delta_L = (3.27 \pm 0.12) \times 10^{-3}\) [22], we expect \(\sigma_{\delta_S-\delta_L/\delta_L} \simeq 0.28\), testing the CPT prediction \(\delta_S = \delta_L\) at a significant level.

Eq. (24) (test of \(\Delta S = \Delta Q\) rule) involves the semileptonic rates of \(K_S\) and \(K_L\); thus to estimate the error on \(\eta\) one has to take into account also the experimental errors on tagging branching ratios and on \(K_{S,L}\) widths. Using the values in Ref. [22], these effects give a large contribution to the total error, which turns out to be \(\sigma_\eta = 1.1 \times 10^{-2}\), whereas the pure statistical contribution would give only \(= 1.4 \times 10^{-3}\). This large value for \(\sigma_\eta\) will perhaps be lowered by measuring all the quantities involved in the same experimental set-up.

In Table 1 we report the predicted sensitivity of DAΦNE in comparison with other experiments. As one can see, DAΦNE is very powerful to test \(\Delta S = \Delta Q\) rule.

Table 1: Comparison between the present experimental data [22], CPLEAR present and expected sensitivity [23] and the achievable sensitivity in 1 year at DAΦNE, for the semileptonic parameters. For both CPLEAR and DAΦNE only the statistical error has been reported. Note that \(A_T\) and \(A_{CPT}\) asymmetries have different theoretical expressions, for CPLEAR and DAΦNE, if one considers CPT violation in the decay amplitudes.
4.3 Direct tests of T and CPT symmetries

The dilepton events allow direct tests of T and CPT symmetries [2, 10]. A long time ago Kabir [24] showed that T violation implies different probabilities for $K^0 \to \bar{K}^0$ and $\bar{K}^0 \to K^0$ transitions, while CPT requires equal probabilities for $K^0 \to K^0$ and $\bar{K}^0 \to \bar{K}^0$ transitions. Then a T-violating asymmetry:

$$A_T = \frac{P (\bar{K}^0 \to K^0) - P (K^0 \to \bar{K}^0)}{P (\bar{K}^0 \to K^0) + P (K^0 \to \bar{K}^0)}$$ (28)

and a CPT-violating one:

$$A_{CPT} = \frac{P (K^0 \to K^0) - P (\bar{K}^0 \to \bar{K}^0)}{P (\bar{K}^0 \to K^0) + P (K^0 \to \bar{K}^0)}$$ (29)

can be defined.

Both these tests can be done at a $\phi$ factory, where the initial state is an antisymmetric $K^0\bar{K}^0$ state, if the $\Delta S = \Delta Q$ rule holds.

If a neutral kaon decays into a positive lepton at a time $t$, the other neutral kaon is at the same time a $\bar{K}^0$ and the sign of the lepton, emitted in a subsequent semileptonic decay, signals if the $\bar{K}^0$ has changed or conserved its own flavour. Therefore, if $|A(K^0 \to l^+x)|^2 = |A(\bar{K}^0 \to l^-x)|^2$, the charge asymmetry in equal-sign dilepton pairs measured at the $\phi$ factory will be equal to $A_T$. On the other hand, time asymmetry in opposite-sign dilepton pairs signals CPT violation.

In the more general case, taking into account also possible violations of the $\Delta S = \Delta Q$ rule one gets4:

$$A_T = \frac{L^{++} - L^{--}}{L^{++} + L^{--}} = 2 \Re (\epsilon_L + \epsilon_S) + 4 \Re \left( \frac{b}{a} \right) = \delta_L + \delta_S,$$ (30)

and

$$A_{CPT} = \frac{L^{--} - L^{+-}}{L^{--} + L^{+-}} = 2 \Re (\epsilon_L - \epsilon_S) + 4 \Re \left( \frac{d^*}{a} \right) + 4 \Re \left( \epsilon_L + \epsilon_S \right) \Re \left( \frac{e^*}{a} \right)
+ \frac{4}{S_L} \left[ \Im (\epsilon_L - \epsilon_S) - 2 \Im \left( \frac{e^*}{a} \right) + 2 \Im \left( \epsilon_L + \epsilon_S \right) \Re \left( \frac{e^*}{a} \right) \right] \frac{\Delta m \Gamma_L}{\Gamma^2 + \Delta m^2},$$ (31)

where $L^{+-}$ ($L^{-+}$) is the number of dilepton pairs with the positive lepton emitted before (after) the negative one. The number of equal-sign electron pairs ($L^{++} + L^{--}$) and that of opposite-sign ($L^{+-} + L^{-+}$) expected at DAΦNE is about $3.3 \times 10^5$ events/year, therefore the T- and CPT-violating asymmetries can be measured with a statistical error of about $1.7 \times 10^{-3}$.

4In the following equations we include also the CPT-conserving higher-order terms, namely the ones proportional to $\epsilon_M \frac{e^*}{a}$. 

10
Violation of the $\Delta S = \Delta Q$ rule does not affect eq. (30) but the CPT violation in the decay amplitude contributes together with the true T-violating term $(\epsilon_L + \epsilon_S)$. On the contrary in eq. (31) the effects of CPT violation and $\Delta S = -\Delta Q$ transitions cannot be disentangled. In the CPT limit the time asymmetry can be written as:

$$\tilde{A}_{CPT} = 8R(\epsilon_M)E \left( \frac{c^*}{a} \right) - 8 \frac{\Re \epsilon_M}{S_L} \frac{\Delta m \Gamma_L}{\Gamma^2 + \Delta m^2}$$

and inserting the experimental limits on $c^*/a$ [22] one has:

$$|\tilde{A}_{CPT}| < 1.1 \times 10^{-3}.$$  

Thus a value of $A_{CPT}$ larger than $10^{-3}$ indicates an actual CPT violation either in the kaon mass matrix or in $\Delta S = -\Delta Q$ transition amplitudes.

More information can be obtained by the study of the time dependence of opposite sign dilepton events. Choosing for the final states of eq. (8) $|a\rangle = |e^+ \pi^- \nu\rangle$ and $|b\rangle = |e^- \pi^+ \bar{\nu}\rangle$ and integrating over the phase space one gets:

$$I(e^+, e^-; t) = \frac{\Gamma^e_{L}}{8 \Gamma_{S}} e^{-\frac{|t|}{\Gamma}} \left[ 1 + 4 R \Delta - 4 R \left( \frac{d^*}{a} \right) - 8 \Re \epsilon_M \Re \left( \frac{c^*}{a} \right) \right] e^{-\frac{|t|}{\Gamma}}$$

$$+ \left[ 1 - 4 R \Delta + 4 R \left( \frac{d^*}{a} \right) + 8 \Re \epsilon_M \Re \left( \frac{c^*}{a} \right) \right] e^{\frac{|t|}{\Gamma}} + 2 \cos(\Delta m t)$$

$$-8 \left[ R \Delta + R \left( \frac{c^*}{a} \right) - 2 \Re \epsilon_M \Re \left( \frac{c^*}{a} \right) \sin(\Delta m t) \right]$$

$$= \frac{\Gamma^{e}_{L}}{4 \Gamma_{S}} e^{-\frac{|t|}{\Gamma}} \left[ \cosh \left( \frac{\Delta m t}{2} \right) + \cos(\Delta m t) - 4 \Delta_R \sinh \left( \frac{\Delta m t}{2} \right) - 4 \Delta_I \sin(\Delta m t) \right]$$

where

$$\Delta_R = R \Delta - R \left( \frac{d^*}{a} \right) - 2 R \Re \epsilon_M \Re \left( \frac{c^*}{a} \right), \quad \Delta_I = R \Delta + R \left( \frac{c^*}{a} \right) - 2 \Re \epsilon_M \Re \left( \frac{c^*}{a} \right).$$

The difference in the asymptotic limits ($|t| \gg \tau_S$) leads to the determination of $\Delta_R$, while the interference term singles out $\Delta_I$. The higher-order terms can be neglected (their upper bound is about $0.6 \times 10^{-4}$, smaller than the DA$\Phi$NE sensitivity), but the CPT-violating parameter $\Delta$ and the $\Delta S = -\Delta Q$ contributions are still mixed. An exact determination of the statistical error on $\Delta_R$ and $\Delta_I$ would require a simulation of the experimental apparatus, which is beyond the purpose of this work. To give an idea of the DA$\Phi$NE sensitivity we report in Fig. 3 the asymmetry in opposite-sign dileptons as a function of the time difference

$$A_{CPT}(t) = \frac{I(e^+, e^-; |t|) - I(e^+, e^-; -|t|)}{I(e^+, e^-; |t|) + I(e^+, e^-; -|t|)},$$

for $\Delta_I = 0$ and $\Delta_I = \pm 5 \Delta_R$. As can be seen the asymptotic value is reached very soon and the three curves are clearly distinct. Therefore we estimate $\sigma_{\Delta_R} \simeq \sigma_{A_{CPT}}/4 \simeq 5 \times 10^{-4}$.  

11
Figure 3: The asymmetry $A_{CPT}(t)$ as a function of the time difference for $\Delta R = 1/4$. The full, dashed and dot-dashed lines correspond to $\Delta_I = 0$, $\Delta_I = 5\Delta_R$ and $\Delta_I = -5\Delta_R$ respectively.

The value of $\sigma_{\Delta I}$ depends critically on the experimental resolution. We estimate that, as happens for the real and the imaginary parts of $\xi$, $\sigma_{\Delta_I}$ will be about 20 times larger than $\sigma_{\Delta_R}$.

As shown in Ref. [20], the inclusion in the analysis of the $K \to \pi\pi$ decays allows us to disentangle almost all the amplitudes. Indeed, in the Wu-Yang phase convention,\(^5\) unitarity implies that the phase of $\epsilon_M$ is equal to $\phi_{SW} \equiv \arctan(2\Delta m/\Delta \Gamma) = (43.64 \pm 0.15)^\circ$ and the phase of $[\Delta - \Re(B_0)/A_0]$ is $[\phi_{SW} \pm \frac{\pi}{2}]$; therefore, one has [10, 20]:

$$\frac{1}{3}(2\eta^{++} + \eta^{00}) = |\epsilon_M|e^{i\phi_{SW}} \pm i|\Delta - \frac{\Re B_0}{A_0}|e^{i\phi_{SW}}. \quad (37)$$

The present experimental data on $\eta^{++}$ and $\eta^{00}$ [22] give:

$$|\Delta - \frac{\Re B_0}{A_0}| = (1.7 \pm 2.8) \times 10^{-5} \quad \text{and} \quad |\epsilon_M| = (2.266 \pm 0.017) \times 10^{-3}. \quad (38)$$

As can be seen, the CPT constraint is at present very well satisfied and, assuming CPT conservation in decay amplitudes, the limit in $K^0\bar{K}^0$ mass difference is

$$\frac{|M_{11} - M_{22}|}{m_K} \leq 10^{-18} \text{ GeV}, \quad (39)$$

\(^5\)The $\pi\pi$ decay amplitudes are parametrized in each isospin channel like the semileptonic ones, $A_I$ is the CPT-conserving part and $B_I$ the CPT-violating one. The Wu-Yang convention is $\Im(A_0) = 0$. 

12
close to the natural scale factor $m_K/M_{Planck}$.

In addition, from the measured value of $K_L$ charge asymmetry one gets:

$$-\Re \Delta + \Re \left( \frac{b}{a} \right) + \Re \left( \frac{d^*}{a} \right) = (-0.06 \pm 0.6) \times 10^{-4}.$$  \hspace{1cm} (40)

The future measurement of $\delta_S$ at DAΦNE would lead also to the determination of $\Re(b/a)$, while the CPLEAR experiment will give direct measurement of $\Re c_S$ and of $\Im(c^*/a)$. Therefore all the parameters that appear in the observables introduced above can be disentangled, and some consistency relations must be satisfied. The preliminary data of the CPLEAR collaboration [23] have large errors and still do not give significant bounds. We report in Table 2 the relations between the observables and the theoretical parameters with the corresponding statistical errors from present and future experiments, together with the consistency equations and the corresponding sensitivity. To simplify the notations of the table we define

$$w = \Delta - \frac{\Re B_0}{A_0} = \epsilon_M - \frac{1}{3} (2\eta^{++} + \eta^{00}).$$  \hspace{1cm} (41)

Table 2: Statistical errors on parameters and consistency relations, using present experimental data [22] (for $\eta^{++}$, $\eta^{00}$ and $\delta_L$) together with DAΦNE (for $\delta_S$, $A_T$, $\Delta_R$ and $\Delta_I$) and CPLEAR (for $\Re c_S$ and $\Im(c^*/a)$) future results. The $\sigma$ of the last equation in the table is only a guess.

5 $K_S \rightarrow 3\pi$

The $K_S \rightarrow 3\pi^0$ decay is a pure CP-violating transition, while the $K_S \rightarrow \pi^+\pi^-\pi^0$ decay receives both CP-conserving and CP-violating contributions.

The CP-conserving $K \rightarrow 3\pi$ decay amplitudes are well described by Chiral Perturbation Theory (ChPT). They have been calculated, including the next-to-leading-order
corrections, in Ref. [25] and turn out to be in good agreement with the experimental data. The CP-conserving $K_S \rightarrow \pi^+\pi^-\pi^0$ decay amplitude is odd under $\pi^+ - \pi^-$ momenta exchange and thus, neglecting final states with high angular momenta, it is induced by a $\Delta I = 3/2$ transition. The ChPT calculation of Ref. [25] leads to the prediction:

$$Br(K_S \rightarrow \pi^+\pi^-\pi^0)_{CP^+} = (2.4 \pm 0.7) \times 10^{-7},$$

consistent with the recent data:

$$Br(K_S \rightarrow \pi^+\pi^-\pi^0)_{CP^+} = (3.9^{+5.4}_{-1.8} \pm 0.9) \times 10^{-7}, \quad E621 [26]$$

$$Br(K_S \rightarrow \pi^+\pi^-\pi^0)_{CP^+} = (7.8^{+5.7}_{-4.1} \pm 7.3) \times 10^{-7}, \quad CPLEAR [23]$$

As in $K \rightarrow 2\pi$ decays, for the CP-violating amplitudes it is convenient to define the ratios:

$$\eta^{+0} = \frac{(A^{+0}_{S})_{CP^+}}{A^{+0}_{L}} = \epsilon_S + \epsilon_{+0},$$

$$\eta^{000} = \frac{A^{000}}{A^{000}_{L}} = \epsilon_S + \epsilon_{000}. \tag{46}$$

The direct CP-violating parameters $\epsilon_{+0}$ and $\epsilon_{000}$ have been evaluated at lowest order in ChPT [27] and turn out to be of the same order as $\epsilon'$. As shown in [28], higher-order terms can substantially enhance $\epsilon_{+0}$ and $\epsilon_{000}$ which are nevertheless negligible$^6$ compared to $\epsilon$. The predicted branching ratios are:

$$Br(K_S \rightarrow (\pi^+\pi^-\pi^0)_{CP^+}) \simeq 1.06 \times 10^{-9},$$

$$Br(K_S \rightarrow 3\pi^0) \simeq 1.94 \times 10^{-9}, \tag{48}$$

much smaller then the present upper limits [22, 23, 29].

Due to the smallness of the branching ratios it is very hard to detect $K_S \rightarrow 3\pi$ decays, especially the CP-violating ones. Tagging the $K_S$ as in the case of the semileptonic decays (eqs. (25) and (26)) and inserting the numerical values, one gets for $3\pi^0$ final state:

$$N_S(3\pi^0) = N_0 Br(K_L \rightarrow 3\pi^0) [3.8 \times 10^{-4} |\eta^{000}|^2 + 8.9 \times 10^{-10} - 1.8 \times 10^{-10} \Im(\eta^{000})]. \tag{49}$$

The total number of events is very small ($\simeq 6$ per year) and the ratio of right events (those with a $K_S \rightarrow 3\pi^0$ decay) to wrong ones (those with a $K_L \rightarrow 3\pi^0$ decay) is only 2.2.

In the case of the CP-conserving $K_S \rightarrow \pi^+\pi^-\pi^0$ decay, the expected number of events is about 440 with a negligible background.

$^6$In $K \rightarrow 3\pi$ we will neglect possible CPT-violating effects, thus in the following we will assume $\epsilon_S = \epsilon_L = \epsilon$. 

Figure 4: The asymmetries $A^{000}(t)$ (full line) and $A^{+0}(t)$ (dashed line). We have fixed $\eta^{000} = \eta^{+0} = |\epsilon| e^{i\phi_{SW}}$.

A more promising way to detect the CP-violating $K_S \to 3\pi$ decays is to study the interference terms of $I(a,b; t)$, in eq. (8), choosing $|a\rangle = |3\pi\rangle$ and $|b\rangle = |l^{\pm}\pi^{\mp}\nu\rangle$, as suggested in Refs. [30, 31]. For the $K_S \to 3\pi^0$ it is useful to define the asymmetry:

$$A^{000}(t) = \frac{\int [I(3\pi^0, l^+\pi^-\nu; t) - I(3\pi^0, l^-\pi^+\nu; t)] d\phi_{3\pi} d\phi_{l\pi\nu}}{\int [I(3\pi^0, l^+\pi^-\nu; t) + I(3\pi^0, l^-\pi^+\nu; t)] d\phi_{3\pi} d\phi_{l\pi\nu}}$$

(50)

which, integrating over the $3\pi$ and $\pi l\nu$ Dalitz plots, becomes:

$$A^{000}(t) = \frac{2\Re \epsilon e^{\frac{i\Delta m t}{2}} - 2\Re (\eta^{000} e^{i\Delta m t})}{\epsilon^2 + \eta^{000} \eta^{+0} e^{-\frac{i\Delta m t}{2}}}. \quad (51)$$

For positive and large values of the time difference $t$, eq. (51) reads: $A^{000} \simeq 2\Re\epsilon$; on the other hand, for negative value of $t$, one gets an interesting interference effect between $\epsilon$ and $\eta^{000}$, as shown in Fig. 4. The asymmetry for $t < 0$ is quite large, but the total number of events is small, about $2 \times 10^3$ per year.

In the case of the $\pi^+\pi^-\pi^0$ final state, the CP-violating and CP-conserving amplitudes have opposite symmetry under $\pi^+ \to \pi^-$ momentum exchange. Therefore it is possible to select the CP-violating and the CP-conserving part of the interference term in eq. (8) with an even or an odd integration over the $3\pi$ Dalitz plot. Analogously to the $3\pi^0$ case, for the CP-violating part we define the asymmetry:

$$A^{+0}(t) = \frac{\int [I(\pi^+\pi^-\pi^0, l^+\pi^-\nu; t) - I(\pi^+\pi^-\pi^0, l^-\pi^+\nu; t)] d\phi_{3\pi} d\phi_{l\pi\nu}}{\int [I(\pi^+\pi^-\pi^0, l^+\pi^-\nu; t) + I(\pi^+\pi^-\pi^0, l^-\pi^+\nu; t)] d\phi_{3\pi} d\phi_{l\pi\nu}}$$

15
Figure 5: The ratio $R^+(t)$ defined in eq.(53). The full, dashed and dotted lines correspond to $\delta = 0$, $\delta = 0.2$ and $\delta = 0.4$ respectively.

$$
R^+(t) = \frac{2(\Re e) e^{+i\Delta t} - 2\Re(\eta^+ e^{i\Delta t})}{e^{+i\Delta t} + \frac{e^{+i\Delta t}}{1 + e^{-i\Delta t}}},
$$

(52)

while the CP-conserving part can be singled out by the ratio:

$$
R^\pm(t) = \frac{\int_+ I(\pi^+\pi^-\pi^0, l^\pm\pi\nu; t) d\phi_{3\pi} d\phi_{l\pi\nu} - \int_- I(\pi^+\pi^-\pi^0, l^\pm\pi\nu; t) d\phi_{3\pi} d\phi_{l\pi\nu}}{\int [I(\pi^+\pi^-\pi^0, l^\pm\pi\nu; t)] d\phi_{3\pi} d\phi_{l\pi\nu}},
$$

(53)

where $f_\pm d\phi_{3\pi}$ indicates the integration in the region $E_{\pi\pm} > E_{\pi\pi}$.

The behaviour of $A^+({}^{000}(t)$ is completely analogous to the one of $A^{000}(t)$ (Fig. 4). As discussed in refs. [30, 31] the study of $R^\pm(t)$ will certainly lead to a determination of the $(A^+_S{}^{000})_{CP+}$ amplitude, performing an interesting test of ChPT in the $\Delta I = 3/2$ transitions, and perhaps could also lead to a direct measurement of the $\pi^+\pi^-\pi^0$ rescattering functions. The phase $\tilde{\delta}$ of eq. (53) can be written as:

$$
\tilde{\delta} \simeq \delta_{1S} - \delta_2,
$$

(54)

where $\delta_2$ and $\delta_{1S}$ are the $3\pi$ strong phases of the $I = 2$ and of the symmetric $I = 1$ final states, respectively. The ChPT prediction is $\tilde{\delta} = (10 \pm 1)^\circ$ [31] and the first measurement [26] gives $\tilde{\delta} = (59 \pm 48)^\circ$. With a different integration over the Dalitz plot, also the phase of the non-symmetric $I = 1$ final state could be selected [30, 31]. Figure 5 shows the behaviour of $R^\pm$ for different values of $\delta$. 

16
6 Interference in $K \to \pi \pi \gamma$

In this section we will discuss the possibility to detect CP violation through the study of the time difference distribution $I(a, b; t)$, defined in eq. (8), choosing $|a\rangle = |\pi^- \pi^- \gamma\rangle$ and $|b\rangle = |\pi^+ \pi^+ \nu\rangle$ [30]. To this purpose we recall some useful decomposition of the $K \to \pi^+ \pi^- \gamma$ decay amplitude, referring to [9] for a more detailed discussion of these decays.

The amplitude for $K(p_\nu) \to \pi^+(p_+) \pi^-(p_-) \gamma(q, \varepsilon)$ decays can be generally decomposed as the sum of two terms: the inner bremsstrahlung ($A_{IB}$) and the direct emission ($A_{DE}$) [9]. The first term, which has a pole at zero photon energy, is completely predicted by QED in terms of the $K \to \pi^+ \pi^- \gamma$ amplitude [32]:

$$A_{IB}(K_{S,L} \to \pi^+ \pi^- \gamma) = e \left( \frac{\varepsilon \cdot p_-}{q \cdot p_-} - \frac{\varepsilon \cdot p_+}{q \cdot p_+} \right) A(K_{S,L} \to \pi^+ \pi^-) .$$

(55)

The second term, which is obtained by subtracting $A_{IB}$ from the total amplitude, depends on the structure of the $K \to \pi^+ \pi^- \gamma$ effective vertex and provides a test for mesonic interaction models.

The $K \to \pi^+ \pi^- \gamma$ amplitude is usually decomposed also in a different way, separating the electric and the magnetic terms. Defining the dimensionless amplitudes $E$ and $M$ as in [33], we can write:

$$A(K_{S,L} \to \pi^+ \pi^- \gamma) = \varepsilon_\mu(q) \left[ E(z_i) (p_+ \cdot q p^\mu_+ - p_- \cdot q p^\mu_-) + M(z_i) \varepsilon^\mu\nu\rho\sigma p_+ p_- q_\nu q_\rho \right] / m_K^3 ,$$

(56)

where

$$z_\pm = \frac{p_\pm \cdot q}{m_K^2}, \quad \text{and} \quad z_3 = \frac{p_\nu \cdot q}{m_K^2} = z_+ + z_- .$$

(57)

As can be seen from eq. (55), the inner bremsstrahlung amplitude can contribute only to the $E(z_i)$ term, while the direct emission amplitude can contribute to both the $E(z_i)$ and the $M(z_i)$ terms. Summing over photon helicities there is no interference between electric and magnetic terms:

$$d\Gamma = \frac{m_K}{(4\pi)^3} \left[ |E(z_i)|^2 + |M(z_i)|^2 \right] \left[ z_+ z_- (1 - 2z_3 - 2r_m^2) - r_m^2 (z_+^2 + z_-^2) \right] dz_+ dz_- ,$$

(58)

($r_m = m_\pi/m_K$). Thus the two contributions $A_{IB}$ and $A_{DE}^{electric}$ can interfere in the $E(z_i)$ amplitude, contrary to the case of the amplitude $M(z_i)$ where only a direct emission contribution appears:

$$|A(K_{S,L} \to \pi^+ \pi^- \gamma)|^2 = |A_{IB}|^2 + 2R \{ A_{IB}^* A_{DE}^{electric} \} + |A_{DE}^{electric}|^2 + |A_{magnetic}|^2 .$$

(59)

Finally the magnetic and the electric direct emission amplitudes can be decomposed in a multipole expansion (see Refs. [9, 34]). Since higher multipoles are suppressed by angular momentum barrier, in the following we will consider only the lowest multipole component.
(the dipole one). In this approximation the electric amplitude is CP-conserving in the $K_S$ decay and CP-violating in the $K_L$ one, while the magnetic amplitude is CP-conserving in the $K_L$ decay and CP-violating in the $K_S$ one. For this reason, since $A_{1B}$ is enhanced by the pole at zero photon energy, the $K_S$ decay is completely dominated by the electric transition, while electric and magnetic contributions are of the same order in the $K_L$ decay.

Similar to $K \to 2\pi$ and $K \to 3\pi$ cases it is convenient to introduce the CP-violating parameter:

$$\eta_{+-\gamma} = \frac{A(K_L \to \pi^+\pi^-\gamma)_{IB+E_1}}{A(K_S \to \pi^+\pi^-\gamma)_{IB+E_1}},$$  \hspace{1cm} (60)$$

where the subscript $E_1$ indicates that only the lowest multipole component of the electric direct emission amplitude has been considered. Using eq. (55) we can write:

$$\eta_{+-\gamma} = \eta_{+-} + \epsilon_{\pi\pi\gamma} \frac{A(K_S \to \pi^+\pi^-\gamma)_{E_1}}{A(K_S \to \pi^+\pi^-\gamma)_{IB+E_1}} \approx \eta_{+-} + \epsilon_{\pi\pi\gamma} \frac{A(K_S \to \pi^+\pi^-\gamma)_{E_1}}{A(K_S \to \pi^+\pi^-\gamma)_{IB}},$$  \hspace{1cm} (61)$$

where $\eta_{+-}$ is the usual $K \to 2\pi$ CP-violating parameter. The term proportional to $\epsilon_{\pi\pi\gamma}$ in eq. (61) is a direct CP-violating contribution, not related to the $K \to \pi\pi$ amplitude and consequently not suppressed by the $1/22$ factor of the $\Delta I = 1/2$ rule. However, although $\epsilon_{\pi\pi\gamma}$ could be much larger than $\epsilon_{\pi\pi}$, the second term in eq. (61) is suppressed by the factor $A_{E1}/A_{1B} \ll 1$.

The $\eta_{+-\gamma}$ parameter has already been measured at Fermilab obtaining for the IB contribution [35]

$$|\eta_{+-\gamma(IB)}| \approx \left| \frac{A(K_L \to \pi^+\pi^-\gamma)_{IB}}{A(K_S \to \pi^+\pi^-\gamma)_{IB}} \right| = (2.414 \pm 0.065 \pm 0.062) \times 10^{-3};$$ \hspace{1cm} (62)$$

$$\phi_{+-\gamma(IB)} = \text{arg}(\eta_{+-\gamma(IB)}) = (45.47 \pm 3.61 \pm 2.40)^\circ.$$ \hspace{1cm} (63)$$

DAΦNE should improve these limits by studying the time evolution of the decay.

Referring to [36] for an extensive analysis, here we show how to take advantage of the $\phi$-factories possibilities to measure $\eta_{+-\gamma}$. Choosing as final states $f_1 = \pi^+l^+\nu$, $f_2 = \pi^+\pi^-\gamma$ and following the notation of Section 2, the time difference distribution, integrated over final phase space, is given by:

$$I(\pi^+l^+\nu, \pi^+\pi^-\gamma; t < 0) = \frac{\Gamma(K_L \to \pi^+l^+\nu)\Gamma(K_S \to \pi^+\pi^-\gamma)}{2\Gamma} \left\{ R_L e^{-\Gamma t} |t| + e^{-\Gamma t} \right\}$$

$$\pm \frac{2e^{-\Gamma |t|}}{\Gamma(K_S \to \pi^+\pi^-\gamma)} \left[ \Re \langle E \rangle_{int} \cos(\Delta m |t|) + \Im \langle E \rangle_{int} \sin(\Delta m |t|) \right],$$ \hspace{1cm} (64)$$

where $R_L = \Gamma(K_L \to \pi^+\pi^-\gamma)/\Gamma(K_S \to \pi^+\pi^-\gamma)$ and

$$\langle E \rangle_{int} \equiv \frac{m_K}{(4\pi)^3} \int d\omega_1 dz_1 \int d\omega_2 dz_2 (E_{1B}^S + E_{2B}^S)(E_{1B}^I + E_{2B}^I) \times$$

$$\times [z_+ z_- (1 - 2z_3 - 2r_m^2) - r_m^2 (z_+^2 + z_-^2)].$$ \hspace{1cm} (65)$$

\footnote{In the following we neglect possible violations of CPT and of the $\Delta S = \Delta Q$ rule.}
Neglecting the phase space dependence of $\eta_{+\gamma}$ one should have \( \langle E \rangle_{\text{int}} = \eta_{+\gamma} \Gamma(K_S \to \pi^+\pi^-\gamma), \) and therefore the interference term of eq. (64) measures the CP-violating $K_L \to \pi^+\pi^-\gamma$ amplitude. The expression for $t > 0$ is obtained by interchanging $\Gamma_S \leftrightarrow \Gamma_L$ and changing the sign of the $\sin(\Delta m |t|)$ term. By fitting the experimental data with the theoretical expression of eq. (64), one should be able to measure the interference term and then improve the measurement of $\eta_{+\gamma}$. Very useful to this purpose will be the difference among the fluxes defined in eq. (64) with positive and negative lepton charges, as discussed for $K_S \to 3\pi$ decays.

To conclude, we remark that not only the semileptonic tagging but also the $K \to 2\pi$ one can be used to measure $\eta_{+\gamma}$ [30].

7 C-even background

Some years ago it was pointed out that the radiative $\phi$ decay ($\phi \to \gamma f_0(980) \to \gamma(K^0\bar{K}^0)_{C=+}$) could have a non-negligible branching ratio and therefore could spoil the power of a $\phi$ factory in measuring $\xi$ and to single out the suppressed $K_S$ decays [12]. More recent determinations of the resonant contribution consider also the $a_0(980)$, $f_0(980)$ interference effect and give a much lower value: the ratio

$$ r = \frac{Br(\phi \to \gamma (K^0\bar{K}^0)_{C+})}{Br(\phi \to (K^0\bar{K}^0)_{C-})}, \quad (66) $$

is estimated to be in the range $(3 \times 10^{-7}) - (5 \times 10^{-9})$ [13].

These predictions are strongly model-dependent and larger values could perhaps be obtained; however we can trust that $r$ is certainly smaller than $10^{-4}$. The non-resonant contribution to $\phi \to \gamma K^0\bar{K}^0$ has been evaluated in the current algebra framework [36] to be of the order of $10^{-9}$, comparable to the lower predictions of [13]. As we will show, the effects of the C-even background on the DAFNE measurements are negligible also for unrealistically large values of $r$.

The C-even $K^0\bar{K}^0$ state can be written as:

$$ \frac{1}{\sqrt{2}} [K^0(+)\bar{K}^0(-) + K^0(-)\bar{K}^0(+)] $$

$$ \approx \frac{1}{\sqrt{2}} [K^0_S(+)K^0_S(-) - K^0_L(+)K^0_L(-) - 2\Delta(K^0_S(+)K^0_L(-) + K^0_L(+)K^0_S(-))], \quad (67) $$

where terms of order $\epsilon^2$ have been neglected but the effect of possible CPT violation has been included.

The $K_SK_S$ component has a CP-conserving decay into the $|2\pi, 2\pi\rangle$ final states and could be a dangerous background in the $\xi_\epsilon$ measurement. However, the time difference distribution of these events,

$$ \mathcal{F}(t) = \frac{\Gamma^+_S \Gamma^0_S}{2\Gamma^+_S} e^{-\Gamma_S t}, \quad (68) $$
is symmetric and cannot simulate the effect of $\epsilon'$. Furthermore, it vanishes very rapidly for large values of $|l|$, and therefore it does not affect the determination of $\Re(\epsilon')$. In effect, as shown in [37], by means of a suitable cut the background contribution can be eliminated in the event sample used to determine $\Re(\epsilon')$, also for very large values of $r$.

The background contribution overlaps the signal just in the interference zone, $d \simeq d_s$, worsening the resolution on $\Re(\epsilon')$. However the signal $(K_L K_S \rightarrow \pi^0 \pi^0, \pi^\pm \pi^-)$ and the background $(K S K_S \rightarrow \pi^0 \pi^0, \pi^\pm \pi^-)$ have different spatial behaviour, which is of help in disentangling the signal contribution from the background. The C-even background has been added to the signal in the fitting procedure of [18] and the accuracy achievable on $\Re(\epsilon')$ has been estimated again. The result is that for a realistic vertex resolution the worsening is around 5%, even if $r$ would be as large as $10^{-4}$.

The $K_L K_L$ component can affect the determination of the suppressed $K_S$ branching ratios and the corresponding CP-violating asymmetries, as we will discuss in the following.

If the $K_S$ semileptonic decays are tagged as in eq. (25), the number of events generated by a single C-even $K^0 \bar{K}^0$ pair is:

$$\overline{N}(l^\pm) = Br(K_L \rightarrow l^\pm \pi^\mp \nu) Br(K_L \rightarrow x_L) S_1 (1 - e^{-10^\tau \Gamma_L / T})$$

then eq. (27) is modified in:

$$N_S(l^\pm)_{\exp} = 0.22 \times N_0 \left[ Br(K_S \rightarrow l^\pm \pi^\mp \nu) + r \cdot \frac{10^\tau \Gamma_L}{\Gamma_S} Br(K_L \rightarrow l^\pm \pi^\mp \nu) \right],$$

and the measured charge asymmetry becomes:

$$\left( \delta_S \right)_{\exp} = \frac{N_S(l^+)_{\exp} - N_S(l^-)_{\exp}}{N_S(l^+)_{\exp} + N_S(l^-)_{\exp}} = \frac{\delta_S + 10^\tau \delta_L}{1 + 10^\tau \delta_L}.$$  

As can be seen the correction is absolutely negligible and cannot simulate CPT violation, in fact $\left( \delta_S \right)_{\exp} - \delta_L = (\delta_S - \delta_L)/(1 + 10^\tau \delta_L)$.

The number of equal-sign dilepton events generated by $(K^0 \bar{K}^0)_{C=\pm}$ is:

$$\overline{L}^{\pm+} = \frac{1}{2} Br(K_L \rightarrow l^\pm \pi^- \nu) Br(K_L \rightarrow l^\pm \pi^- \nu) S_L \cdot S_L,$$  

and that of opposite sign is:

$$\overline{L}^{\pm-} = \overline{L}^{+-} = \frac{1}{2} Br(K_L \rightarrow l^\pm \pi^- \nu) Br(K_L \rightarrow l^- \pi^+ \nu) S_L \cdot S_L.$$

Therefore the experimentally measured T- and CPT-violating asymmetries are:

$$\left( A_T \right)_{\exp} = \frac{\delta_S + \delta_L + 87r(2\delta_L)}{1 + 87r},$$

and

$$\left( A_{CPT} \right)_{\exp} = \frac{A_{CPT}}{1 + 87r}.$$
Figure 6: The effect of the C-even background on $A^{000}(t)$. The full line corresponds to $r = 0$ and the dashed one to $r = 3 \times 10^{-7}$.

Also in this case the effect of the C-even background is negligible and the CPT prediction $A_T = 2\delta_L$ is still valid.

Finally we discuss the effect of C-even background in $K_S \to 3\pi$ decays, where the largest influence is expected.

The inclusion of the background contribution in eq. (49) gives:

$$\begin{align*}
(N_S(3\pi^0))_{\exp} &= N_0 Br(K_L \to 3\pi^0) \times \\
&\times \left[3.8 \times 10^{-4}|\eta^{000}|^2 + 8.9 \times 10^{-10} - 1.8 \times 10^{-10} \Re(\eta^{000}) + 3.8 \times 10^{-3} r\right].
\end{align*}$$

(76)

Therefore, for $r \geq 10^{-7}$ the background is comparable to the signal, enforcing the conclusion that the direct tag of the $K_S$ is not useful to determine $\text{Br}(K_S \to (3\pi)_{CP-})$. On the contrary, if the $K_S \to (\pi^+\pi^-\pi^0)_{CP+}$ branching ratio is $\sim 10^{-7}$, in agreement with ChPT predictions and preliminary CPLEAR results, the background contribution to this decay can be neglected and the corresponding branching ratio can be measured.

The modifications induced in interference measurements require a more detailed study. The analogue of the time difference distribution defined in eq. (8) for an initial $K_L \bar{K}_L$ state is

$$\bar{T}(a,b;t) = \frac{1}{2\Gamma_L}|A_L(a)A_L(b)|^2 e^{-r_L|t|}(1 - e^{-2D/\Gamma_L + 2|\Gamma_L|}|t|),$$

(77)

where the last factor accounts for having both $K_L$ decays inside the detector. Thus the C-even background, which is symmetric in $\pi^+\pi^-$ momenta, modifies eqs. (51, 52) in the
following way:

\[
(A^{000}(t))_{\text{exp}} = \frac{2\Re \left[ e^{+\frac{\Delta T}{2} t} + r \frac{1}{\Gamma} e^{+\frac{\Delta T}{2} t} \left( 1 - e^{-2D/d_{L} + 2\Gamma_{L} t} \right) \right] - 2\Re \left( \eta^{000} e^{i\Delta m t} \right)}{e^{+\frac{\Delta T}{2} t} + [\eta^{000}]^{2} e^{-\frac{\Delta T}{2} t} + r \frac{1}{\Gamma} e^{+\frac{\Delta T}{2} t} \left( 1 - e^{-2D/d_{L} + 2\Gamma_{L} t} \right)},
\]

and

\[
(A^{+-0}(t))_{\text{exp}} = \frac{2\Re \left[ e^{+\frac{\Delta T}{2} t} + r \frac{1}{\Gamma} e^{+\frac{\Delta T}{2} t} \left( 1 - e^{-2D/d_{L} + 2\Gamma_{L} t} \right) \right] - 2\Re \left( \eta^{+-0} e^{i\Delta m t} \right)}{e^{+\frac{\Delta T}{2} t} + [\eta^{+-0}]^{2} e^{-\frac{\Delta T}{2} t} + r \frac{1}{\Gamma} e^{+\frac{\Delta T}{2} t} \left( 1 - e^{-2D/d_{L} + 2\Gamma_{L} t} \right)}.
\]

The contribution of the C-even background becomes important (especially in the numerator) for large and negative values of the time difference, where the number of events is absolutely negligible, but, as can be seen from Fig. 6, does not affect the results for \( t \geq -10\tau_{S} \).

In the CP-conserving ratio \( R^{\pm}(t) \) the C-even background contributes in the denominator only and can be safely neglected.

8 Quantum mechanics violations

Research in the theory of quantum gravity has led to a proposal for a modification of quantum mechanics time evolution [14, 15], which might transform a pure initial state into an incoherent mixture. This effect becomes particularly interesting in the kaon system, where quantum oscillations can be accurately measured. Moreover the \( \phi \)-factory, where the initial \( K^{0}\overline{K}^{0} \) is an antisymmetric coherent state, is a very suitable facility to test this idea. We will not discuss the theoretical models of quantum mechanics violations [14, 15] but, following the analysis of Ref. [16], we shall analyze some examples of observable effects at DAΦNE.

To describe the time evolution to incoherent states, one has to introduce the formalism of the density matrix. In Ref. [15] it has been proposed to modify the quantum mechanics time evolution equation in the following way:

\[
i \frac{d}{dt} \rho = H \rho - \rho H^\dagger + \tilde{H} \rho,
\]

where \( \rho \) is the \( 2 \times 2 \) kaon density matrix, \( H = M - i\Gamma/2 \) is the usual non-Hermitian kaon Hamiltonian (see eq. (18)) and \( \tilde{H} \rho \) is the quantum mechanics violating term. For \( \tilde{H} = 0 \) the eigenmatrices of eq. (80) are the usual matrices:

\[
\rho_{LL} = |K_{L}\rangle\langle K_{L}|, \hspace{1cm} \rho_{SS} = |K_{S}\rangle\langle K_{S}|,
\]

\[
\rho_{SL} = |K_{S}\rangle\langle K_{L}|, \hspace{1cm} \rho_{LS} = |K_{L}\rangle\langle K_{S}|.
\]

Under reasonable assumptions (probability conservation, not decreasing entropy and strangeness conservation) \( \tilde{H} \) can be expressed in terms of the three real parameters \( \alpha, \beta \)
and $\gamma$ of Ref. [15]. With this parametrization the new eigenmatrices become:

\[
\tilde{\rho}_{LL} = \rho_{LL} + \left[ \frac{\gamma}{\Delta \Gamma} + 4\beta \frac{\Delta m}{\Delta \lambda^2} \left( \frac{e_L}{\Delta \lambda^2} - \frac{\beta^2}{\Delta \lambda^2} \right) \right] |K_1\rangle\langle K_1| \\
+ \frac{\beta}{\Delta \lambda} |K_1\rangle\langle K_2| + \frac{\beta}{\Delta \lambda} |K_2\rangle\langle K_1|
\]

\[
\tilde{\rho}_{SS} = \rho_{SS} - \left[ \frac{\gamma}{\Delta \Gamma} + 4\beta \frac{\Delta m}{\Delta \lambda^2} \left( \frac{e_S}{\Delta \lambda^2} - \frac{\beta^2}{\Delta \lambda^2} \right) \right] |K_2\rangle\langle K_2| \\
- \frac{\beta}{\Delta \lambda} |K_1\rangle\langle K_2| + \frac{\beta}{\Delta \lambda} |K_2\rangle\langle K_1|
\]

\[
\tilde{\rho}_{SL} = \rho_{SL} - \frac{\beta}{\Delta \lambda} |K_1\rangle\langle K_1| + \frac{\beta}{\Delta \lambda} |K_2\rangle\langle K_2| - i \frac{\alpha}{2\Delta m} |K_2\rangle\langle K_1| \\
\tilde{\rho}_{LS} = \rho_{LS} - \frac{\beta}{\Delta \lambda} |K_1\rangle\langle K_1| + \frac{\beta}{\Delta \lambda} |K_2\rangle\langle K_2| - i \frac{\alpha}{2\Delta m} |K_1\rangle\langle K_2|,
\]

(82)

where $|K_{1,2}\rangle$ are the usual CP eigenstates and

\[
\Delta \lambda = \Delta m + i \frac{\Delta \Gamma}{2} = |\Delta \lambda| e^{i(\pi/2-\phi_{SW})}.
\]

(83)

The analysis of fixed target experiments has led the authors of Ref. [16] to put stringent bounds on the quantum mechanics violating parameters $\beta$ and $\gamma$:

\[
\beta = (0.32 \pm 0.29) \times 10^{-18} \text{GeV},
\]

\[
\gamma = (-0.2 \pm 2.2) \times 10^{-21} \text{GeV}.
\]

(84)

Quite similar results have been obtained in [38], where also a bound for $\alpha$ ($\alpha \leq 4.8 \times 10^{-16} \text{GeV}$) is derived. It is interesting to note that, using the values in eq. (84), the limits on $\alpha/m_K$ and $\beta/m_K$ turn out to be of the order of $m_K/M_{Planck}$, which could be the natural suppression factor for these parameters.

These limits have been obtained assuming that there is no CPT violation in the decay amplitudes. In the more general case the effects of $\beta$, $\gamma$ and those of the conventional CPT-violating terms are mixed together.

This situation could be improved at DAΦNE. In effect, quantum mechanics predicts a vanishing amplitude for the transition to the final state $\{f(t_1), f(t_2)\}$, with $t_1 = t_2$, independently from possible CPT violations. Therefore, as pointed out in [16], any measurement of equal time $f_1 = f_2 = f$ events can give a bound for pure quantum mechanics violations. It should be stressed however that the finite experimental resolution will partially wash out these effects (see Fig. 2). Moreover, also the C-even background gives rise to equal time events. Thus only the time distribution, which is different for C-even background and quantum mechanics violations, could help in disentangling them.

In Ref. [16] the consequences of quantum mechanics violation to several DAΦNE observables have been analyzed. In particular the explicit formula of the $|\pi^+\pi^-, \pi^0\pi^0\rangle$
Figure 7: The time asymmetry $A(t)$ for $\Re(\zeta') = 5 \times 10^{-4}$. The full lines correspond to quantum mechanics predictions of eqs. (11) and (12), with $\Im(\zeta') = -4 \times 10^{-3}$ (a), 0 (b) and $4 \times 10^{-3}$ (c). The dashed lines correspond to the predictions of [16] with the upper bounds of quantum mechanics violating parameters $\beta = 0.71 \times 10^{-18} \text{GeV}$ and $\gamma = 2.2 \times 10^{-21} \text{GeV}$, for the previous values of $\Im(\zeta')$.

time difference distribution has been derived, discussing the quantum mechanics violating effects in the measurement of $\zeta'$. For $t \gg \tau_S$ the time asymmetry of eq. (11) becomes:

$$A(t) \overset{\Delta S}{=} 3\Re(\zeta') \left[ 1 - \frac{\gamma}{\sqrt{2} |\Delta\lambda||e|} - 2 \frac{\beta}{|\Delta\lambda||e|} \right] - 3\Im(\zeta') \left[ 2 \frac{\beta}{|\Delta\lambda||e|} \right]. \quad (85)$$

In Fig. 7 we have plotted $A(t)$ in the usual quantum mechanics case and in the quantum mechanics violating case (following the analysis of [16]), for $\Re(\zeta') = 5 \times 10^{-4}$ and $\Im(\zeta') = -4 \times 10^{-3}$, 0 and $+4 \times 10^{-3}$ (close to the predicted DAΦNE sensitivity). The quantum mechanics violating parameters have been chosen to be: $\beta = 0.71 \times 10^{-18} \text{GeV}$ and $\gamma = 2.2 \times 10^{-21} \text{GeV}$, in order to maximize their effects. As one can see, for very small values of the time difference $t$ the effects of quantum mechanics violations are striking, but probably beyond any realistic experimental resolution. The determination of $\Im(\zeta')$ should not be affected, but an effect could be present in the asymptotic value of the asymmetry where, contrary to the usual quantum mechanics case, also $\Im(\zeta')$ contributes.

Using the expressions of Ref. [16] and neglecting a possible violation of the $\Delta S = \Delta Q$ rule, we have calculated also the quantum mechanics violating effects for eq. (25). The
measured charge asymmetry for $K_S$ semileptonic decays would become:

$$
(\delta_S)^{\exp} = \left( \frac{N_S(l^+)}{N_S(l^-)} \right)^{\exp} = \frac{\delta_S - 2\Re \left( \frac{\beta}{\Delta M} \right) + 4\sqrt{2} \frac{\beta}{\Delta M} + 20 \frac{\gamma}{\Delta t} \delta_L}{1 + 20 \frac{\gamma}{\Delta t}},
$$

where $\delta_{S,L}$ are the usual asymmetries, as defined in eq. (23). The effect of the $\gamma$ term simulates a C-even background and interestingly, with the limit of eq. (84), this correction turns out to be of the order of the one estimated in the previous section (for $r \sim 10^{-5}$). The $\beta$ term simulates a CPT violation, however, using the bound in eq. (84), this effect turns out to be smaller than the DAΦNE sensitivity.

Concluding, we can say that quantum mechanics violating effects can be neglected in integrated asymmetries at DAΦNE. Nevertheless, if $\alpha$, $\beta$ and $\gamma$ were suppressed only linearly by $m_K/M_{Planck}$, some effects in time-dependent distributions could be observable. An estimate of DAΦNE sensitivity on these effects would require an accurate simulation of the experimental apparatus, which is beyond the purpose of this work.

9 Conclusions

From the previous analysis it is clear that a $\phi$ factory is very suitable for an accurate study of the origin of CP violation in $K_S$ and $K_L$ decays and to test the Standard Model predictions.

The real part of the ratio $\zeta^r$, which is a clear signal of direct CP violation, can be measured with high precision, about $10^{-4}$. A non-vanishing value of the imaginary part of $\zeta^r$, which would imply CPT violation, can be detected up to some units in $10^{-3}$. Even if the fixed target experiments will reach a similar sensitivity, the KLOE apparatus has a completely different systematics and such experimental result will be very important.

The presence of a pure $K_S$ beam will allow, for the first time, the direct detection of CP violation in $K_S$ decays. Moreover many interesting tests of T and CPT symmetries (in addition to $\Im(\zeta^r)$) can be performed.

The combined analysis of DAΦNE, CPLEAR, E731 and NA31 experiments will allow to disentangle the CPT-violating contributions in decay amplitudes from those in mass matrix and also the $\Delta S = -\Delta Q$ transitions can be singled out. All the real parts of the parameters could be bounded up to $\simeq 5 \times 10^{-4}$ while a lower sensitivity ($\sim 10^{-3}$–$10^{-2}$) is expected for the imaginary parts.

More doubtful is the situation for $K_S \rightarrow 3\pi$ decays. We think that the CP-conserving decays will certainly be measured and some information on the rescattering phases could be obtained. For the CP-violating ones we observe, without doing a complete statistical analysis, that the shape of the interference effect of Fig. 4 is very characteristic and could easily be detected over a flat background. The analysis of the possibility to measure $\eta_{+-\gamma}$ leads to similar conclusions.
Also the recent suggestions on possible quantum mechanics violations might be tested at DAΦNE.

Acknowledgements
We wish to thank V. Patera and N. Paver for very useful suggestions and comments. We acknowledge also the members of the DAΦNE working groups for interesting discussions.
